EXPERIMENTS carried out on five samples of tallow showed that the gradients of the temperature-hardness and temperature-compression curves were proportional to the titre tests (solidif. pt. of insoluble fatty acids). The samples examined had the following titre values: mutton tallow with 15% of stearine, 48·6° C.; mutton tallow, 48·1° C.; beef tallow, 46·1° C.; beef tallow and "C" grade beef tallow, 48·25° C.; "C" grade beef tallow, 42·2° C. Hardness tests were carried out in a modified Brinell tester, in which a steel ball ⅜" in diam. was crushed into the surface of the tallow by the impact from a weight of 0·25 lb. falling a distance of 6" on to a steel rod or piston in contact with the upper surface of the ball. Depth of sinkage was registered directly by a lever acting from a collar on the piston to a scale reading to 0·001" by means of a vernier. Both hardness (expressed in arbitrary units) and compression (in tons per sq. ft.) were found to be proportional at a number of temperatures below the titre figure to the titre number, and the hardness test is recommended for ascertaining the suitability of tallows for launching purposes. The load-sustaining power and also the titre value of an unknown tallow can be conveniently determined by interpolation from reference to curves correlating these figures on known samples. The load-sustaining power at different temperatures may similarly be interpolated. Purified recovered tallow is unsatisfactory owing to its brittle and crumbly character. As a lubricant for use between the general ways and the sliding way, a mixture of "Vaxel" (a lime-resin-oil soap softened with mineral oil) and soft soap proved the most efficacious in inhibiting amalgamation of the tallow surfaces. The effect of boiling a natural tallow for 4 hrs. was to increase the hardness, the hardness factor falling from 101 units to 71 units (a hardness factor of zero on the scale corresponding to an actual hardness of infinity).—A. de W.

PATENTS.

Fatty acids in fats and oils; Neutralisation of ——. E. R. Bolton and E. J. Lush. E.P. 159,58?, 28.11.19.

THE free fatty acids in an oil or fat are neutralised by subjecting the oil or fat in an inert gas to the action of the chemically equivalent proportion of mono- and di-glycerides of the fatty acids separately prepared, at a temperature of, *e.g.*, 250° C. for about 3 hrs. The neutralised product is subsequently heated *in vacuo* in the same reaction vessel to evaporate the water chemically formed. The neutralised oils can be refined by ordinary processes, *e.g.*, for the production of edible oils. —A. de W.

Fat; Manufacture of —— *from spent sulphite cellulose lyes.* W. Jeroch, and Reichsausschuss für pflanzl. u. tier. Oele und Fette Ges. E.P. 146,430, 3.7.20. Conv., 24.1.17.

SEE G.P. 305,091 of 1917; J., 1920, 663 A.

Fat and glue-water. E.P. 137,842. *See* XV.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins used for making varnishes; Characters of ——. P. Nicolardot and C. Coffignier. Chim. et Ind., 1921, 5, 150—156. (*Cf.* J., 1911, 815.)

AN apparatus for determining the relative hardness of different resins consists essentially of a support for a test-block of the resin and a vertical weighted rod carrying at its lower end a steel ball which presses on the surface of the resin. Usually the ball has a diameter of 2 mm. and the rod is weighted with 5 kg.; the diameter of the impression made in the resin is measured after 5 secs. and again after 10 mins., or at other periods during which the pressure is applied. The test is applied at 0° C. or at 25° C. Resins are classified as follows: — *Hard resins:* Zanzibar, Madagascar, Demerara. *Semi-hard resins:* Congo, Benguela, Cameroon, Angola red, Kissel, Brazil, Angola white, Sierra Leone. *Soft resins: Aucoumea Klaineana, Hopea odorata, H. dealbata.* Various: Yellow amber, cloudy amber, kauri, Manila, pontianac.—W. P. S.

Gum-oleoresin of Boswellia serrata; Extraction of turpentine, resin, and gum from the —— without the use of solvents. G. J. Fowler and M. A. Malandkar. J. Ind. Inst. Sci., 1921, 4, 27—42.

The turpentine is first removed from the oleoresin by distillation with wet steam. The yield amounted to 8—9%, and the oil, which was pale yellow, had the following constants: sp. gr. 0·8435 at 30° C., $[\alpha]_D=+4° 54'$, fraction distilling below 160° C. 81%, 160°—180° C. 14·4%. The gum-resin remaining after the removal of the turpentine is heated with about three times its weight of water in an autoclave at 30 lb. pressure, whereby the hydrated resin rises to the surface and solidifies on cooling, whilst the gum forms a flocculent precipitate or mucilage on the bottom of the vessel. The resin after dehydration by heating to about 130° C. forms a brown transparent mass, amounting to 54% of the original gum-resin and not differing appreciably in appearance from that extracted by a solvent. It has the following constants: acid value 51·6, saponif. value 51·3, iodine value 108·1. The gum on drying forms a dark grey mass, amounting to 23% of the original gum resin. It forms a mucilage with water of but feeble adhesive power.—G. F. M.

Colophony; Constitution of the resin acids of ——. A. Grün. Z. Deuts. Oel- u. Fettind., 1921, 41, 49—52. Chem. Zentr., 1921, 92, I., 496.

From a consideration of earlier experiments (*cf.* J., 1919, 506 A), the author considers that abietic acid does not contain two double bonds, but, like pinene, one double bond and a bridge linkage. A formula is proposed which is claimed to explain better than those hitherto suggested the known properties of the compound and to be in conformity with its origin from pinene. The formation of abietic acid takes place by union of one molecule each of α- and β-pinene, and subsequent oxidation of a methyl to a carboxyl group. By different modes of combination of the two molecules of pinene, a series of abietic and pimaric acids could be formed and others could be formed in an analogous manner from camphene or fenchene.—A. de W.

Low-temperature tar. Fischer and Ehrhardt. *See* III.

Patents.

[Concrete paint or] composition impervious to oil, spirit, water, and the like. Anti-corrosive paint or composition. C. H. Ivinson and G. S. Roberts. E.P. (A) 159,542, and (B) 159,543, 28.10.19.

(A) A composition for coating concrete, etc., consists of the double chlorides of zinc and/or magnesium and ammonium, together with oxides of magnesium and/or zinc, and finely-divided iron, with or without the addition of fillers or extenders, *e.g.*, to every ... pts. by weight of a mixture of 25 pts. of zinc oxide, 1 pt. of silica, 0·5 pt. of sodium biborate, and ...5 pt. of powdered glass, are added 14 pts. of zinc chloride and 1 pt. of ammonium chloride. About ... pt. of water may be added to 2 pts. of the combined powders, or the water may be added in the form of a saturated solution of the mixed chlorides. (B) A protective paint for zinc, concrete, wood, and the like, consists of a mixture of asphaltum and a volatile solvent with acid-resisting or anti-corrosive substances, *e.g.*, aluminium, calcium, or magnesium oleates or stearates, gum elemi, masticated rubber, gutta-percha, or paraffin wax, and fillers, *e.g.*, asbestos, silica, etc., together with lime-proof pigments ground in a suitable medium, *e.g.*, ferric oxide, lithopone, or zinc oxide ground in linseed or tung oil, thinners, or a drying oil varnish.
—A. de W.

Paint or varnish and method of making the same. M. Darrin, Assr. to The Koppers Co. U.S.P. 1,370,195, 1.3.21. Appl., 10.5.19.

A paint or varnish comprises a resin obtained from solvent naphtha subjected to an autoclave process, and linseed oil.—A. de W.

Paint; Water-resistant ——. R. Plönnis. G.P. 301,783, 17.9.16.

The paint consists of calcium carbonate as a pigment and a mixture of potassium silicate (water-glass) and potassium hydroxide as a medium.
—A. R. P.

Gum from grass trees (Xanthorrhœa); Process for the extraction of ——. H. J. Pooley and J. L. Strevens. E.P. 160,080, 12.3.20.

The outside portions of the grass tree are extracted, at a temperature of not less than 160° F. (71° C.), with the alcoholic solvent derived from the fermentation and rectification of the sweet wort obtained by exhaustion of the inner core of the tree with warm water, such solvent being concentrated to a strength of at least 70% of alcohol. Extraction of the gum may be carried out either by percolation or exhaustion with the vapour of the alcoholic solvent, and the dissolved gum may be separated from the solvent by distillation.—A. de W.

[Rosin soap] emulsions; Method of making ——. J. A. De Cew, Assr. to Process Engineers, Inc. U.S.P. 1,370,884, 8.3.21. Appl., 11.11.20.

Hot rosin soap containing free rosin is diluted by agitating 1 pt. of hot size with 7 pts. of hot water, with subsequent addition of cooler water.—L. A. C.

Linoleum, lincrusta, artificial leather, etc.; Production of ——. G. Ruth and E. Asser. G.P. 328,580, 21.6.19.

A mixture of equal parts of chromium or aluminium naphthenate heated to 250°—260° and of a metal salt of naphthenic acid heated to 160° C. is used. A naphthenate partly decomposed by heating to 200° C. may also be used.—H. J. H.

Oils, boiled oils, varnishes, oily pastes, and luting compositions; Preparation of ——. Rostschutz-Farbwerke Liebreich, G.m.b.H. G.P. 330,670, 25.12.19.

The oils etc. are heated to at least 240° C. with metals or oxides of metals (CuO, ZnO) conferring little or no siccative properties, whereby the compound formed remains unsaponified in the presence of alkaline lyes etc. The oils may also be heated with driers and metallic oxides together.—A. de W.

Shoe-creams, wax-, metal-, wood- and leather-polishes; Preparation of ——. P. Friesenhahn. G.P. 331,050, 5.7.19.

The usual solid constituents of such preparations are dissolved or emulsified in cyclohexanols or cyclohexanones or their homologues either alone or together with other solvents. The syrupy nature of the products of the hydrogenation of phenols is favourable to the retardation of the drying of the finished products and facilitates emulsification of the solid constituents.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Polythionic chlorides. Bruni and Amadori. *See* VII.

Patents.

Rubber; Manufacture of ——. S. C. Davidson. E.P. 159,602, 1.12.19 and 19.1.20.

Fresh latex is treated with a dilute alkaline solution of phenol (E.P. 11,470 of 1912, 13,438 of 1913,

and 22,138 of 1914; J., 1913, 799; 1914, 758; 1915, 1020), which acts as a preservative and permits the postponement of further treatment for any desired period. The latex is subsequently coagulated by the addition of a suitable acid or of a suitable mixture of a salt such as magnesium sulphate with sulphuric or pyroligneous acid (*e.g.*, in the apparatus described in E.P. 22,489 of 1914), the dehydration of the resulting coagulum being facilitated by fine perforations in the manner already described (E.P. 151,344; J., 1920, 757 A). The coagulum is then rolled into sheet or crêpe and, if desired, pressed into block. By this procedure the rubber is brought into a marketable condition in a much shorter time than usual.—D. F. T.

Rubber mix and process of compounding rubber. R. C. Hartong, Assr. to The Goodyear Tire and Rubber Co. U.S.P. 1,370,965, 8.3.21. Appl., 30.1.19.

RUBBER is well mixed with water containing aluminium hydroxide in suspension and the water is driven off from the mixture, which is then vulcanised in the usual manner.—A. R. P.

Plastic, rubber-like material from cellulose esters; Manufacture of ——. F. Clouth, Rheinische Gummiwaarenfabr. m.b.H. G.P. 324,944, 18.12.17. Addn. to 319,723 (J., 1920, 568 A).

OTHER high-boiling oils, such as creosote oil, are used instead of anthracene oil, as described in the chief patent.—L. A. C.

Rubber-like products; Hindering oxidation in synthetic ——. Badische Anilin- und Soda-Fabr. G.P. 330,741, 27.2.18.

THE addition of 1% of α- or β-naphthol, resorcinol, or quinol, to the material before vulcanisation yields a product which does not deteriorate during storage.—L. A. C.

Adhesive solutions; Manufacture of highly —— *from varieties of artificial rubber which are insoluble or soluble with difficulty in the usual solvents, or give solutions of little adhesive power.* Akkumulatoren-Fabr. A.-G. G.P. 331,031, 6.12.17.

THE rubber is heated in air to at least its melting point, *i.e.*, about 140° C., under a pressure of about 1 atm., and is subsequently cooled, cut up, and dissolved in petroleum spirit.—L. A. C.

Substance resembling rubber; Manufacture of a ——. F. de la Rosée. G.P. 331,334, 15.2.18.

RESIN, *e.g.*, balsam resin, is melted with calcium chloride, and repeatedly distilled with further additions of calcium chloride and bleaching powder. A mixture of the oily product with rubber or rubber regenerates is then vulcanised.—L. A. C.

Caoutchouc; Art of vulcanising ——. C. W. Bedford, Assr. to The Goodyear Tire and Rubber Co. U.S.P. 1,371,662—4, 15.3.21. Appl., 6.1.17, 19.3.19, and 17.5.19.

SEE E.P. 130,857 of 1918; J., 1919, 731 A.

XV.—LEATHER; BONE; HORN; GLUE.

Depsides and tannins. K. Freudenberg. Collegium, 1921, 10—19.

A HISTORICAL account of Fischer's synthesis of gallotannic acid and tannin-like substances. Carbomethoxybenzoic acid was prepared from *p*-hydroxybenzoic acid and was converted, by means of the Schotten-Baumann reaction, into an ester anhydride of *p*-hydroxybenzoic acid. This was termed a depside. By partial saponification of triacetylgallic acid to diacetylgallic acid and combination of the free hydroxyl group with triacetylgalloyl chloride, a penta-acetyl-*m*-digallic acid was obtained, which proved to be a true tannin, like the corresponding didepsides of the dihydroxybenzoic acids. There yet remained the 7% of dextrose obtained from gallotannic acid, which was not easily liberated, and hence was not present in the form of a glucoside. The absence of free carboxyl groups in gallotannic acid indicated that the carboxyl groups in gallic acid were united to the hydroxyl groups in the dextrose. Fischer and Bergmann prepared pentadigalloylglucose and found it very similar to Chinese gallotannic acid. It was not identical, since the natural product consists of a mixture of isomers, whilst the synthetic product was a single substance. The synthesis of fully methylated gallotannic acid was also effected. The comparison of pentagalloylglucose with Turkish gallotannic acid was rendered difficult owing to the presence of an ellagic acid tannin in the natural product. Glucogallin, a constituent of rhubarb, was identified by Fischer and Bergmann as 1-galloyl-β-glucose, and was synthesised from acetobromoglucose and silver triacetylgallate. Fischer worked out a new method for preparing partially acetylated glucose derivatives. Two molecules of acetone are combined with one of dextrose in presence of a little hydrochloric acid, forming a diacetoneglucose. The free hydroxyl group is combined with an acid chloride and the acetone is split off one molecule at a time. Further developments have been along the lines of analysis with tannase which has helped to explain the constitution of chlorogenic acid ($C_{16}H_{18}O_9$). By its aid, hamameli-tannin was shown to consist of a new sugar esterified with two molecules of gallic acid. Chebulinic acid from myrobalans contains a digalloylglucose combined with an unknown acid. There are four groups of tannins, ester tannins, catechins, oak and chestnut, and ellagic acid tannin. Crystalline tannins are difficultly soluble in water, amorphous tannins are more readily soluble.—D. W.

Oakwood extracts; Cause of the development of gas in ——. F. Liebert. Collegium, 1921, 76—77.

A SAMPLE of strongly fermenting extract was inoculated on a plate of malt extract-gelatin and kept at 22° C. for 2 days. A pure yeast culture was obtained which closely resembled *Saccharomyces apiculatus*. This is an extraordinary instance of selective growth of yeasts to the exclusion of bacteria and moulds. The infection was traced to exposure of the concentrated extract to the air after being run out of the evaporator. Covers and disinfection prevented it. The acidity of the extract also helped the growth of the yeast, and an extract neutralised with calcium carbonate would not ferment.—D. W.

Tannin analysis. I. V. Kubelka and B. Köhler. Collegium, 1921, 77—83.

AFTER shaking solutions of certain solid pine bark and oak wood extracts with hide powder in accordance with the provisions of the official method of analysis, and filtering, the filtrate gave a precipitate with gelatin and with iron salts and was coloured. A fresh portion of hide powder absorbed a large amount of matter from this filtrate and rendered it "tannin-free" according to qualitative tests. Similar observations were made with liquid extracts, but the maximum amount of matter absorbed from the first filtrate (10%) was obtained with solid extracts. Samples of an oak bark extract tested by four different analysts gave results showing variation in tans from 38·6% to 45·7% by the "shake" method. In tanning practice with some materials, the hide is first entered into nearly exhausted liquors, whereas in the analysis the powder is treated with freshly made

iquor. The "shake" method was worked out for ertain tanning materials and is not suitable for ome new products. The principle of the official nethod is wrong, since all those substances which re not quickly absorbed are classified as non-tans, lthough they may be capable of being absorbed by ide powder and react with gelatin and iron salts. n the filter method of analysis, the first layers of ide powder are saturated with tannin from the resh strong tannin solution and then the other ayers come into contact with the partially de-annised solution. Where the "shake" method oes not give completely detannised solutions, the filter" method should be employed. Tables are ppended showing the suitability of the "shake" ethod of analysis for quebracho, mimosa, chest-ut, and sumach extracts and the efficacy of the ouble shake method and filter bell method with akwood, oak and pine bark extracts.—D. W.

anning [and dyeing] rabbit skins for furs. G. Desmurs. J. Soc. Leather Trades' Chem., 1921, 5, 84—87.

KINS of rabbits and similar animals are tanned in quors made up from a mixture of 100 pts. of un-lphited quebracho tannin (40% tans), 10 pts. of much extract (22% tans), 2½ pt. of anhydrous dium sulphate, and ½ pt. of aluminium sulphate. similar mixture is also suitable for tanning sheep-ins in the paddle. After a preliminary treat-ent with sodium carbonate, ammonia, or caustic da, the furs are dyed black with logwood and stic and mordanted with copper sulphate or pyro-nite of iron. Grey, brownish-black, or greyish-own shades can be obained with *p*-phenylene-amine, *o*- and *p*-aminophenol, *m*-toluylenedi-ine and hydrogen peroxide.—D. W.

lehyde tannage. VI. W. Moeller. Collegium, 1921, 20—31. (*Cf.* J., 1920, 36 A, 730 A.)

RMALDEHYDE is absorbed in large amounts by imal charcoal under special conditions. The lume and concentration of the formaldehyde solu-ns and the time factor have been overlooked in vious researches. The assertion that formalde-de does not act on agar-agar is not borne out by eriment. The action of dilute solutions of maldehyde on hide powder has been determined. 55% of the formaldehyde present in a 3·5% ution was adsorbed by the hide powder after days' contact. The amount of formaldehyde orbed increases with the length of time of tact. Similar results were obtained with tralised solutions of formaldehyde, but much was absorbed from concentrated solutions. The ition of alkali even to neutralise the formalde-e solution causes the Cannizzaro inversion to eed to a certain extent, the polymerisation of formaldehyde, and further the reaction of the decomposition products with a certain portion he formaldehyde to form methyleneamino-acids. se reactions must cause the neutralised form-hyde solution to react acid, and three different tions of formaldehyde were found to be acid r being in contact with hide powder for 14 days. methyleneamino-acids have a hydrolysing on, hence the "proteolytic-constant" of hide ler is increased by formaldehyde solutions. lack of permanency in formaldehyde-tanned ers is easily explained by insufficient washing e tanned leather. Methyleneamino-acids re-in the leather and they slowly hydrolyse the , causing brittleness. There is not as much of hide substance with 15—30% solutions of ldehyde owing to the more intense tannage. total acid formed in these concentrated solu-is the same as that formed in the dilute solu-. Samples of powder tanned with formalde-solutions of different strengths were extracted with water and those tanned in concentrated solutions were found to be less stable to the solvent action of water, and powders tanned in neutral formaldehyde solutions were less stable than the others. The small amount of formaldehyde-tannin taken up in alkaline solution gives all the desired properties required for aldehyde-leather, and the absolute amount of formaldehyde-tannin taken up is not a vital factor.—D. W.

Mineral tannages. IV. W. Moeller. Collegium, 1921, 67—75.

NEUTRALISED and unneutralised solutions of ferric chloride of different strengths (1·1%—10·9% Fe_2O_3) were allowed to be in contact with hide powder for periods varying from 1 day to 3 months. Half the total iron absorbed was taken up the first day, after which there was very little increase for a month. Neutralisation of iron salts does not produce a fully satisfactory tanning solution. The electrolytic dissociation of iron salts is excessive and results in hydrolytic decomposition of the hide after prolonged contact. As much as 67% of the hide powder was dissolved by the strongest solutions after 3 months' contact. This explains the "loose" fibre and tendency to become brittle of iron-tanned leathers. The ready dissociation of all iron salts even in neutral solution causes the difficulties connected with iron tannages and renders it difficult to obtain a permanently peptised system. The acid peptiser is continuously dissociating and the acid portion effects the hydrolysis of the hide and the decomposition of the leather. Unlike other tannages, there appears to be no limit to the amount of iron which can be absorbed by the hide. The assertion that mineral salts such as chromium and ferric salts can tan without the addition of soda is not borne out by experiment. The hydrions in such unneutralised solutions decompose the hide with which they are in contact and the hide decomposition products act just like any other alkali. The basic groups combine with the acids and a more or less peptised system results from the presence of these basic decomposition products. The longer such a solution is in contact with the hide substance the more tanning effect it will exert upon the hide. Such a process of tanning is useless for practical purposes, since it does not give a satisfactory leather. Modern processes for iron tannages provide acceptors for the hydrions in the tanning salts in order to obviate their hydrolytic action during tannage and storage.—D. W.

Gelatin jellies; Elastic properties of ——. S. E. Sheppard and S. S. Sweet. J. Amer. Chem. Soc., 1921, 43, 539—547.

MEASUREMENTS of the modulus of rigidity of gelatin jellies under torsion show that they follow Hooke's law nearly to the breaking point, the elastic limit nearly coinciding with the tenacity (*cf.* J., 1920, 758 A). The expression $E=kc^n$ expresses the relation between the modulus of elasticity, E, and the concentration, c, but the constants k and n differ for different grades of gelatin. The elasticity is not a simple function of hydrogen ion concentration in the case of acid jellies. Alcohol and glycerol increase the jelly strength up to a certain concentration. Jellies with more than 40% of alcohol separate into two phases under torsion. The bearing of the results on theories of jelly structure is discussed. (*Cf.* J.C.S., May.)—E. H. R.

Colloidality; The zone of maximum ——. Its relation to viscosity in hydrophile colloids, especially karaya gum and gelatin. J. Alexander. J. Amer. Chem. Soc., 1921, 43, 434—440.

THE viscosity of reversible emulsoid or hydrophile colloids sometimes increases as the dispersed phase becomes finer, as in oil emulsions, and sometimes

as it becomes coarser, as in the case of soaps. There appears, in fact, to be a "zone of maximum colloidality," the size of particles giving maximum viscosity being probably different for different substances. This zone of maximum colloidality is not limited to so-called emulsoid colloids. Thus with steel the Fe_3C—Fe dispersion reaches its maximum hardness in martensite and becomes softer if the dispersion becomes greater (austenite) or less (troostite, sorbite, pearlite). Experiments in which karaya gum of different degrees of fineness was dispersed in water showed that the viscosity increased with increasing fineness of the gum particles from 5- to 10-mesh (about 4 mm.) to 200-mesh (about 0·1 mm.). The hydration and dehydration of karaya gum and gelatin is discussed. The decrease in the viscosity of highly degraded glue or gelatin is probably due to an increase in the dispersion. Both the jelly strength and viscosity of cold aqueous dispersions of commercial ground glues and gelatins increase with decrease in size of particle, but the optimum conditions for maximum viscosity are not identical with those for maximum jelly strength. (*Cf.* J.C.S., May.)—E. H. R.

Proteins [gelatin]; Method of purifying certain kinds of ——. A. M. Field. J. Amer. Chem. Soc., 1921, **43**, 667—668.

In consequence of its amphoteric properties (J., 1919, 331 A), any protein with iso-electric point at a hydrogen-ion concentration greater than that of water will lose any combined basic elements when dialysed sufficiently long against dilute acid, and the resulting protein-acid compound can then be completely converted into protein by dialysis against water. Gelatin purified by this procedure forms an opaque white jelly, free from ash. Similarly, proteins with iso-electric points less than that of water in respect of hydrogen ions may be successively treated with dilute alkali and water. —J. K.

Proteins [gelatin]; Ion series and the physical properties of ——. *III. Action of salts in low concentration.* J. Loeb. J. Gen. Physiol., 1921, **3**, 391—414.

The Hofmeister lyotropic series is founded on an error due to a failure to notice the influence of the added salt on p_H. At the same p_H the effect of ions on the swelling, osmotic pressure, and viscosity of gelatin depends only on the sign and valency of the ions, and univalent ions of the same sign have practically the same effect. Divalent and still more trivalent ions have a greater effect but do not differ much among themselves if they have the same sign. (*Cf.* J.C.S., May.)—G. B.

Proteins [gelatin]; Colloidal behaviour of ——. J. Loeb. J. Gen. Physiol., 1921, **3**, 557—564.

The potential difference between gelatin chloride solutions inside a collodion bag and an aqueous solution outside is depressed by a neutral salt in the same proportion as the osmotic pressure is depressed; the potential difference can be calculated by Nernst's formula if it is assumed to be due to the difference in the p_H measured inside and outside the bag, which latter difference seems to result from the Donnan membrane equilibrium. (*Cf.* J.C.S., May.)—G. B.

Anthrax spores. Müller. *See* XIXB.

Patents.

Tanning of hides and skins; Apparatus for rapid ——. F. Gilardini. E.P. 160,422, 5.12.19. Addn. to 114,631 (J., 1919, 297 A).

Relates to mechanical improvements in the apparatus described in the chief patent.—D. W.

Colouring-matter for leather and method of using the same. J. H. Pfingsten, Assr. to Presto Color Co. U.S.P. 1,371,572, 15.3.21. Appl., 2.7.17.

Pulverulent, insoluble pigment is suspended in water, and the leather is agitated therein in the presence of heat, so that the pigment is uniformly deposited in the interstices of the leather.—D. W.

Glue-water; Apparatus for treating mixtures of fat and —— *derived from boiling and drying organic substances.* K. Niessen. E.P. 137,842, 13.1.20. Conv., 2.10.16.

Two receptacles are arranged side by side with their lower parts connected by a siphon for equalising the pressure. One receptacle of such size that it can hold not only the maximum output of fat from the steriliser but also a small quantity of glue water, serves as fat separator and the other as glue-water holder and evaporator. Both receptacles are connected with a steriliser and glue extractor by means of a series of pipes fitted with valves. By operating the valves the glue-water and fat separate in the fat separator, which is emptied by means of another valve, and the glue-water is returned to the extractor.—D. W.

Ferro-leather; Process for producing ——. W. Mensing. U.S.P. 1,371,803, 15.3.21. Appl., 23.1.17. Renewed 27.1.21.

See G.P. 314,885 of 1916; J., 1920, 199 A.

Artificial leather. G.P. 328,580. *See* XIII.

XVI.—SOILS; FERTILISERS.

Soils; Rate of formation of soluble substances in several organic ——. M. M. McCool and L. C. Wheeting. Soil Sci., 1921, **11**, 233—247.

In organic soils, for a given moisture content, the rate of formation of soluble material varies with the temperature. At higher temperatures (25° C.) optimum moisture conditions tend to bring greater amounts of material into solution than when the soil is saturated. The reverse is true at lower temperatures (7° C.). In moist soils the concentration of soluble substances generally increases on standing up to a certain point and then decreases. In organic soils the amount of soluble substances present and the rate at which they are produced vary with the depth. In general the ability to yield soluble materials decreases regularly from the surface to the water-table, the muck soils studied being very inactive below a depth of 2 ft. The zone of weathering and the region of greatest activity coincide.—W. G.

XVII.—SUGARS; STARCHES; GUMS.

Ammonia; Recovery of —— in beet sugar manufacture. K. Andrlik and V. Skola. Z. Zuckerind. Czechoslov., 1921, 45, 179—182, 187—190, and 195—198.

EXPERIMENTS carried out in a beet sugar factory showed the amount of ammonia liberated reckoned as a percentage of the weight of roots sliced was 0·0019 (12·5% of the total amount) during carbonatation, and 0·0058 (38·4% of the total) during heating; while 0·0074 (49·0% of the total) was dissolved in the condensed waters drained from the quadruple effect evaporator. (*Cf.* J., 1920, 379 A; 1921, 233 A.)—J. P. O.

Saccharimeter; Re-testing the 100° point of the ——. I. Detection of small amounts of invert sugar in the presence of much sucrose. A. Kraisy. Z. Ver. Deuts. Zucker-Ind., 1921, 123—144.

A METHOD of determining reducing sugars which is said to be capable of detecting at least 0·005% in the presence of 10 g. of sucrose is described. Shortly before use 25 c.c. of a solution containing 2 g. Cu (7·86 g. $CuSO_4+5H_2O$) per litre is mixed in a 250 c.c. Erlenmeyer flask with 25 c.c. of a solution containing 3·292 g. of sodium carbonate and 20 g. of Rochelle salt per litre. At the same time, in a second Erlenmeyer flask, 50 c.c. of the sugar solution containing 10 g. of sucrose is mixed with 5 c.c. of $N/10$ $KHCO_3$. Both liquids are separately heated to boiling, the first added to the second, and ebullition continued for exactly 10 min., at the end of which time 50 c.c. of cold, recently boiled distilled water is added. After leaving the flask for 5 min. in cold water, 1—1·25 c.c. of $4N$ HCl is run in, followed immediately by standard iodine (1 c.c. =1 mg. Cu, that is $N/63·57$), the excess of which is then titrated with thiosulphate, using starch solution as indicator. Using this so-called "neutral Fehling's solution," the copper reduced in the case of refined sugars purified by crystallisation from alcohol was 1·5—4·6 mg. Cu; using Striegler's solution, 5·4—9·2; and using ordinary alkaline Fehling's solution it was 36—43, operating in all three cases in the presence of 10 g. of sucrose and under exactly the same conditions. It is concluded that whereas ordinary Fehling's solution is capable of detecting not less than 0·05% of reducing sugars, the reagent now proposed is sufficiently sensitive to establish the presence of 0·002% in samples of refined sugar.—J. P. O.

Sugars; Chemistry of the ——. H. Kiliani. Ber., 1921, 54, 456—472.

MANY examples are given of a new method of using nitric acid with the sugar group. The substance is treated with slightly more than the calculated amount of nitric acid, generally of sp. gr. 1·2 (32% HNO_3); in certain cases a more concentrated acid is used, or, when reaction is difficult, mixtures of the ordinary acid and the fuming acid, or of the fuming acid and water. In all cases it is important that the room temperature should be maintained throughout the oxidation. Arabinose, xylose, and rhamnose are smoothly oxidised to the corresponding monocarboxylic acids or their lactones, but reaction with dextrose appears rather more complex, leading, however, under certain specified conditions to the formation of calcium glycuronate. Under like conditions ketoses do not appear to be affected. A new method for the preparation of lævulose from sucrose and of treating the mixtures of sugars obtained by the hydrolyses of glucosides is thus indicated. As demonstrated by the conversion of metasaccharin into calcium trihydroxyadipate and of *l*-mannonic acid into the lactone of *l*-mannosaccharic acid, a convenient process for the preparation of dicarboxylic acids is given. Further, glyceric and tartronic acids, and probably also glyceraldehyde, are readily prepared from glycerol. Finally, the process forms an excellent means of oxidising (and in many cases of nitrating) organic substances which are attacked by nitric acid of any concentration at the ordinary temperature; thus castor oil is converted into azelaic and, apparently, suberic acids, whilst cinnamic and benzoic acids give mainly *m*-nitrobenzoic acid. —H. W.

Sugars; Unsaturated products of reduction of —— and their transformations. I. The glucal problem. M. Bergmann and H. Schotte. Ber., 1921, 54, 440—455.

ELUCIDATION of the constitution of glucal triacetate (Ber., 1920, 53, 509) has made the formula,

$$\underbrace{OH.CH_2.CH(OH).\overbrace{CH.CH(OH).CH:CH}}_{O}$$

highly probable for the parent substance, but this fails to account for the reducing properties of glucal preparations hitherto examined, unless they can be attributed to the unknown influence of the 2.3-dihydrofuran ring. Examination of the analogously constituted rhamnal,

$$CH:CH.CH(OH)CH.CH(OH)(CH_3)$$
(with O bridging the first CH and the CH before CH(OH)(CH_3))

shows that this is not the case, since the

latter does not behave as an aldehyde. By the use of alcoholic ammonia in place of aqueous barium hydroxide for the hydrolysis of glucal triacetate the authors have succeeded in preparing crystalline glucal, needles, m.p. about 60° C., $[\alpha]^{18}_D = -7.2$ in aqueous solution, which, like rhamnal, does not show aldehydic properties. One of the impurities which confers strong reducing powers on syrupy "baryta" glucal is 2-desoxyglucose. On oxidation with benzoper-acid glucal is converted into mannose. (*Cf.* J.C.S., May.) —H. W.

XVIII.—FERMENTATION INDUSTRIES.

Saccharase [invertase] preparations; Preparation of highly active ——. O. Svanberg. Z. physiol. Chem., 1920, **109**, 65—98. (*Cf.* J., 1920, 636 A, 795 A; 1921, 191 A.)

HIGHLY active invertase preparations were made by autolysing yeast, extracting the residue with water, and fractionating by means of alcohol, protein being removed from the resulting enzyme solutions by treatment with kaolin. A purer preparation was obtained by dialysis.

Yeast; Nutritional requirements of ——. *III. Synthesis of water-soluble B.* V. E. Nelson, E. I. Fulmer, and R. Cessna. J. Biol. Chem., 1921, **46**, 77—81.

A YEAST was sub-cultured 180 times on a salt and sucrose medium, and yet contained enough vitamin B to cure rats. The vitamin, therefore, must have been synthesised by the yeast, which result invalidates Williams's method of estimating this vitamin (*cf.* following abstract). (*Cf.* J.C.S., May.) —G. B.

Vitamins and yeast growth. R. J. Williams. J. Biol. Chem., 1921, **46**, 113—118.

THE author's quantitative test for vitamin B (J., 1919, 692 A; 1920, 608 A) gives results fairly concordant with Osborne and Mendel's rat-feeding experiments, but bakers' yeast, by the yeast method, shows a much higher vitamin content than brewers' yeast, whereas for animal experiments the reverse holds good. "This is interpreted to mean that there is some specificity in growth stimulants, but not necessarily two totally different substances stimulating growth of the two varieties of yeast" (*cf.* preceding abstract).—G. B.

Acetone fermentation process in India. G. J. Fowler, Y. D. Wad, and A. G. Gokhale. J. Ind. Inst. Sci., 1921, **4**, 1—15.

As raw material for the acetone fermentation process, mahua flowers (*Bassia latifolia*), containing 40—60% of total sugars, 0·65—1·1% of nitrogen, and little or no starch, were tried under various conditions but gave very unsatisfactory results. Good fermentations were obtained, however, with starch-containing materials, such as rice, but jawari (cholam) flour was preferred on account of its cheapness. In small scale experiments 1200 g. of jawari flour containing about 52% of starch and 1·2% nitrogen gave about 70 c.c. of acetone and 128 c.c. of butyl alcohol. The most vigorous fermentation took place with cultures only two or three generations from spores, and it is important to ensure that the cultures do not lose their power to sporulate, as they tend to do after continued subculture in simple maize mash. This was achieved by inoculating in a mash containing meat extract, peptone, or gelatin. The chief difficulty in large scale work is the maintenance of sterility up to the point of inoculation 4 hrs.' heating under 15 lb. steam pressure was found to be requisite. The problem of the disposal of the effluent, which amounts to 50,000 galls. per ton of acetone produced, was studied. A cake utilisable for cattle food is obtained by pressing the husk along with the sludge resulting from plain sedimentation. The turbid liquid remaining is clarified by treatment with excess of lime, and gives a further sludge which has valuable manurial properties. In connexion with the above work rough experiments were made on the flashing and explosive concentrations of mixtures of acetone vapour and air, indicating that a concentration of acetone vapour up to 2·3% was safe. The mixture flashes above this concentration, reaching a maximum violence at a concentration of 5·61% of acetone, and settling down to a quiet flame at 10·2% of acetone vapour.—G. F. M.

Iron; Determination of small quantities of —— *in organic liquids, especially in wines.* P. Malvezin and C. Rivalland. Ann. Chim. Analyt., 1921, **3**, 90—92.

THE ash from a portion of the liquid (*e.g.*, from 20 c.c. of wine) is dissolved in 10 c.c. of 5% hydrochloric acid, the solution filtered and treated with 0·5 c.c. of hydrogen peroxide; after 15 mins., the solution is boiled to decompose excess of peroxide, 5 c.c. of 1% copper sulphate solution and 1 c.c. of 2% sodium salicylate solution are added, the mixture is boiled and titrated with thiosulphate solution, the end-point being denoted by the disappearance of the violet coloration (ferric salicylate). The copper sulphate acts as catalyst in the reduction of the ferric salt.—W. P. S.

XIXA.—FOODS.

Dough; Relation between the mechanical properties of —— *and bread-making.* M. Chopin. Bull. Soc. d'Encour., 1921, **133**, 261—273.

AN apparatus is described and figured by means of which it is possible to measure the tenacity of a dough in terms of the effort necessary to cause a sample to assume a given shape in a constant time, and to measure the capacity of the dough to stretch into a thin membrane. It is shown that temperature, composition of the dough, method of working the dough, age of the flour, and length of time the dough is allowed to stand, all have an influence on the results. Measurements with numerous samples of flour show that the difference between the specific volume of bread which can be obtained with a flour and the initial specific volume of the dough from this flour is proportional to the square root of the coefficient of extension of this dough developed in a thin membrane. Thus it is possible to determine the index of swelling during bread-making and the yield of bread from a given flour.—W. G.

Starches, flours, etc.; Commercial classification of ——. Arpin. Ann. Chim. Analyt., 1921, **3**, 74—84.

It is suggested that the word flour be used to describe ground cereals, that the word starch be reserved for the amylaceous products obtained from cereals and grains, and that the amylaceous products of tubers, roots, etc., be called "fecula." Analyses and microscopical characters of these different classes of material are given.—W. P. S.

Milk; Titration of organic acids in ——. B. Kramer and C. H. Greene. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxxviii—xxxix.

The application of Van Slyke and Palmer's method for the estimation of titratable organic acid in urine (J. Biol. Chem., 1920, **41**, 567) to milk is described. 10 c.c. of milk, 50 c.c. of distilled water, 2—5 c.c. of 20% $CuSO_4$, and 10 c.c. of 10% suspension of $Cu(OH)_2$ are successively put into a 100 c.c. volumetric flask, repeatedly shaken, made up to 100 c.c. after 15 min., and filtered through a Buchner funnel. 50 c.c. of the filtrate is titrated with $N/10$ hydrochloric acid, using first 0·5 c.c. of 1% phenolphthalein as indicator, and when this has been decolorised (p_H=8), adding 5 c.c. of 0·02% "tropaeolin 00" and titrating further until the solution matches the standard (0·6 c.c. of 0·2 N HCl, 5 c.c. of "tropaeolin 00," and water to 60 c.c.). Similar large test tubes are used, and a corrective is applied for the 0·1 N hydrochloric acid used in the blank titration of distilled water from p_H 8·0 to 2·7.—G. B.

Milk; Dialysis indicator method for the determination of the hydrogen ion concentration of ——. B. Kramer and C. H. Greene. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xlii—xliii.

The dialysis indicator method of Levy, Rowntree, and Marriott is used. 5 c.c. of milk is dialysed in a collodion sac against an equal volume of 0·9% sodium chloride solution; the level of the salt solution is above that in the sac. After at least 5 mins. the external solution is colorimetrically compared with phosphate or acid phthalate standards and Clark and Lubs' indicators. Parallel electrometric estimations showed excellent agreement. The following values for p_H were found: Human milk, 6·8; cow's milk, 6·4; protein milk, 4·8; butter-milk, 4·4. (*Cf.* Lovatt Evans, J. Physiol., 1921, **54**, 353.) —G. B.

Goat's milk; Acidity of —— in terms of hydrogen ion concentration, with comparisons to that of cow's and human milk. E. W. Schultz and L. R. Chandler. J. Biol. Chem., 1921, **46**, 129—131.

Average goat's milk has p_H 6·53, when fresh, and 3·92 when fully soured. For fresh cow's milk Van Slyke and Baker (J., 1920, 130 A) found 6·5—7·2, mostly 6·5—6·76, and other authors 6·52—6·8; the maximum acidity of soured cow's milk is 4·65. Human milk has p_H between 6·86 and 7·46.—G. B.

Milk; Iron as the cause of formaldehyde and diphenylamine reactions [for nitrates] of ——. F. Reiss. Z. Unters. Nahr. Genussm., 1921, **41**, 26—29.

Milk containing iron yields reactions with formaldehyde and diphenylamine-sulphuric acid reagents indicating the presence of nitrates. The iron may be derived from the cans in which the milk is kept; the colorations obtained can be attributed to the presence of nitrates only when the milk is proved to be free from hydrogen peroxide and from dissolved iron.—W. P. S.

Milk-powder; Determination of moisture in ——. N. Schoorl and S. C. L. Gerritzen. Pharm. Weekblad, 1921, **58**, 370—378.

The determination of moisture in milk-powder by heating for 3—4 hrs., either at 95° or at 103° C., gives results which are 1·6—1·9% too low, as compared with the correct moisture found by exposure *in vacuo* over phosphorus pentoxide for 24 hrs. at 95° C. Addition of sand to the sample does not influence the results. On prolonged heating at 95° C. a very gradual loss in weight takes place, but even after 29 hrs. the correct moisture is not indicated. If drying is continued at 103° C., there is a progressive loss of weight, and at a certain stage decomposition of the milk sugar sets in owing to presence of phosphates in the milk-powder. By drying in air which has been passed through sulphuric acid, a correct moisture figure may be obtained after 36 hrs. A rapid method for moisture determination, giving results correct within 0·1—0·3%, consists in heating the milk-powder in undried air at 110° C. for a period not exceeding 2 hrs., the weighing bottles being placed on an asbestos sheet in the oven to avoid risk of decomposition.—W. J. W.

Casein solutions; Chemical and physical behaviour of ——. J. Loeb. J. Gen. Physiol., 1921, **3**, 557—564.

Extension to casein solutions of conclusions previously arrived at for gelatin and egg albumin that the forces determining the combination between proteins and acids or alkalis are the same forces of primary valency which also determine the reaction between acids and alkalis with crystalloids, and that the valency and not the nature of the ion in combination with a protein determines the effect on the physical properties of the latter. (*Cf.* J.C.S., May.)—G. B.

Proteins; Digestibility of —— in vitro. I. Effect of cooking on the digestibility of phaseolin. H. C. Waterman and C. O. Johns. J. Biol. Chem., 1921, **46**, 9—17.

The protein of the navy bean is rendered more digestible by cooking; 5 minutes' cooking gave a detectable, and 45 minutes' cooking a maximum increase in digestibility.—G. B.

Proteins; Physicochemical method of characterising ——. E. J. Cohn. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., **46**, iii—iv.

The hydrogen ion concentration at iso-electric point gives the ratio of the acid to the basic dissociation constants (1). By plotting the ratio of acid to protein—and of protein to base (expressed as mols. of HCl or NaOH added to 1 g. of anhydrous iso-electric protein)—against hydrogen ion concentration, a titration curve is obtained, and a slope of a tangent to this curve at the iso-electric point represents the apparent strength of the multivalent protein as acid or base (2). Values of (1) and (2) together with the hydrogen ion concentration at the iso-electric point are tabulated for five proteins and show considerable differences.—G. B.

Lecithin. III. Fatty acids of lecithin of the egg-yolk. P. A. Levene and I. P. Rolf. J. Biol., Chem., 1921, **46**, 193—207.

Methods are given for obtaining lecithin (from egg yolk powder) free from fats, cerebrosides, and saturated lipoids, and with a minimum content of amino nitrogen. On hydrolysis about half the fatty acid was found to be oleic acid, the other half a mixture of palmitic and stearic acids. These facts suggest the existence of more than one lecithin in egg-yolk.—G. B.

Foods; Determination of alkalinity and phosphates in the ashes of ——. J. Tillmans and A. Bohrmann. Z. Unters. Nahr. Genussm., 1921, **41**, 1—17.

A PORTION of the ash is boiled with an excess of $N/10$ acid, 30 c.c. of 40% calcium chloride solution is added, and the excess of acid is titrated with $N/10$ alkali, using phenolphthalein as indicator; the number of c.c. (A) of $N/10$ acid used is a measure of the alkalinity (carbonate plus oxide). The carbonate may be determined separately. Another portion of the ash (at least 0·2 g.) is boiled for 1 hr. with 100 c.c. of $N/10$ hydrochloric acid, cooled, filtered, and titrated with $N/10$ sodium hydroxide solution, using methyl orange as indicator; the number of c.c. of $N/10$ acid neutralised by the ash is noted (B). Twenty c.c. of saturated sodium oxalate solution is added and the titration is continued until the mixture is neutral to phenolphthalein (C). If the ash is alkaline, orthophosphates (Y) only can be present and their quantity, in mg. of PO_4, is given by the formula $Y=3/2(B-A)\times3·167$. When the ash is not alkaline, and C has a positive value, orthophosphates and pyrophosphates (Z) are present; in this case $Y=3C\times3·167$ and $Z=2(B-2C)\times4·75$. If C has a negative value, pyrophosphates and metaphosphates (U) are present; then $Z=2B\times5·75$ and $U=-C\times9·5$. Milk ash contains very little true alkalinity, and about 30—40% of phosphate ions in the form of orthophosphate; pyro and metaphosphates are not present. Flour ash is free from true alkalinity and contains a mixture of phosphates. Meat (beef and horse) ash is also free from oxides and carbonates but contains a mixture of ortho and pyrophosphates (6—7% as ortho and 47—50% as pyrophosphate ions). Fruit juice ashes consist mainly of carbonate and the phosphate is present wholly as orthophosphate. The alkalinity of cocoa ash consists of about one-third oxide and two-thirds carbonate; orthophosphate is present.—W. P. S.

Pepsin; Use of edestin in determining proteolytic activity of ——. J. F. Brewster. J. Biol. Chem., 1921, **46**, 119—127.

A MODIFICATION of the method of Fuld and Levison (J., Chem. Soc., 1907, ii., 76) and a method for preparing pure edestin from hemp seeds are described. After mixing various amounts of 1% edestin and $N/10$ hydrochloric acid solutions with equal amounts of 10% sodium chloride in a series of tubes, equal amounts of 1% pepsin are added, and the time necessary to produce a clear solution is noted.
—G. B.

Antiscorbutic properties of commercially dried orange juice. J. F. McClendon, W. S. Bowers, and J. P. Sedgwick. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, ix—xi.

THE dried preparation (*cf.* following abstract) was about as active in preventing guinea-pig scurvy as an equivalent of fresh juice, so that drying did not significantly impair the antiscorbutic properties.
—G. B.

Fat-soluble vitamin. H. Steenbock, M. T. Sell, E. M. Nelson, and M. V. Buell. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxxii—xxxiii.

As in the case of yellow and white maize, the fat-soluble vitamin content runs parallel to the content of yellow pigment in different varieties of carrots, sweet potatoes, and squash. In yellow maize the vitamin is localised in the endosperm, which, in distinction from the embryo, contains most of the pigment. Carotin after numerous crystallisations, is still active on rats, but, on the other hand, very active cod-liver oil may be free from yellow pigment. Light, which destroys the pigment, also destroys vitamin. The latter, obtained from alfalfa (lucerne) hay, was not destroyed by hot saponification, nor by hydrogen peroxide or nascent hydrogen. Crystalline acetyl derivatives of the non-saponifiable vitamin fraction were prepared without destruction of the vitamin.—G. B.

Orange juice; Commercial drying of —— *retaining its antiscorbutic properties.* J. F. McClendon and S. M. Dick. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, x—xi.

A DEHYDRATING unit consists of an octagonal chamber 20 ft. in diameter and 20 ft. high, with 12 hot-air ports in three tiers. The upper tier admits air at a velocity of 300 ft. per min., the middle at 600 ft., and the lower at 150 ft. per min. A centrifugal spray is in the centre, and just below the level of the upper tier of ports. It consists of a hollow shaft (admitting the juice) and a head made of a series of concave discs serrated at their margins (12 in. in diameter). Between the discs is a series of grooved collars distributing the juice from the hollow shaft to the concave sides of the discs. The shaft rotates at 5000 revolutions per minute and transforms the juice into a fog. The air currents retard the falling of the spray. The exhaust ports are at the bottom of the cell and so large as not to retard the falling of the dried juice in the dead air space. The incoming air is at 55°—70° C., but evaporation prevents the juice reaching this temperature; moreover, a droplet is only exposed for 1 min. to hot air. Orange juice is one-eighth solids; on evaporation to one-fifth of its original weight the pectin forms a clot from which a syrup oozes, but on evaporation to one-sixth no clot separates. The high content of monosaccharides makes the dried juice hygroscopic. The taste is not affected by drying. Milk may be dried in the same apparatus and then mixed with the orange preparation to restore the antiscorbutic substance lost in pasteurisation.—G. B.

Antiscorbutic property of some desiccated fruit juices. M. H. Givens and I. G. Macy. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xi—xii.

THE juices of lemons, grapes, tomatoes, raspberries, grape fruit, and orange, dried by the Merrell-Soule Co., Syracuse, N.Y., were examined for antiscorbutic substance in regard to guinea-pigs; all except dried grape and raspberry juices still contained a significant amount; in most cases the products were tested 14—20 months after desiccation. Orange juice was still active when tested two years after being desiccated.—G. B.

Available carbohydrate in thrice boiled vegetables. L. O'Reilly and E. H. McCabe. J. Biol. Chem., 1921, **46**, 83—89.

BOILING vegetables three times has been advocated in order to remove carbohydrate for diabetics. After such treatment canned string beans, cauliflower, pumpkin, cabbage, and carrots still retained 0·5% of carbohydrate as determined by means of taka-diastase. Boiling with 0·05—0·1% sodium carbonate is much more efficient.—G. B.

Sea water; Method for utilisation of the nutritive salts of ——. J. F. McClendon. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxvii.

OCEAN water is treated with phosphoric acid (6g. per l.) and evaporated to complete dryness, giving a non-hygroscopic, non-bitter product containing iodine for the thyroid, fluorine for the teeth, etc. The product may be added to common salt to prevent caking and improve the nutritive qualities of the latter.—G. B.

Feeds; The salt or sodium chloride content of ——. G. S. Fraps and S. Lomanitz. Texas Agr. Exp. Stat., Bull. No. 271, 1920. 14 pages.

To determine the quantity of added salt in fodders, 5·85 g. of the sample is treated with sufficient water to make up 200 c.c. and the mixture shaken for 1 hr.; 80 c.c. of the solution is treated with 1 g. of carbon black or 1 g. of lead acetate, filtered, and 50 c.c. of the filtrate is acidified with nitric acid, an excess of $N/10$ silver nitrate solution is added, and the excess then titrated with $N/10$ thiocyanate solution, using ferric alum as indicator. All unmixed fodders contain but small quantities of sodium chloride, with the exception of alfalfa (lucerne) (1·0%), molasses (1·12%), and some meat products (1·3—2·8%).—W. P. S.

Oxidising nitrogen [e.g., for use in flour bleaching]; Electrodes for ——. F. H. Loring. E.P. 159,709, 31.12.19.

A FLAMING continuous arc is drawn out by means of reciprocating metallic electrodes in a magnetic field, the main axis of which coincides with the axis of the electrodes. For this purpose the lower ferromagnetic electrode or an extension thereof is preferably surrounded by a magnetising coil. The upper electrode may be of copper in tubular form or solid, and in the former case air may be drawn through the tube and passed through the arc. The electrode chamber may be of cast iron to serve as return circuit for the magnetic lines.—J. S. G. T.

Bread-making. C. J. Patterson and R. W. Mitchell. U.S.P. 1,370,354, 1.3.21. Appl., 17.11.19.

THE moisture content of dough of a given consistency is increased by the addition of calcium peroxide, not exceeding 0·007% of the weight of flour. —C. A. K.

Milk food products; Manufacture of ——. C. S. Townsend. E.P. 160,234, 10.12.19.

SKIM milk and vegetable fatty matter each warmed to 75°—100° F. (24°—38° C.) are agitated together, the mixture is emulsified and allowed to stand until lactic acid ether is produced, whereupon the mass is concentrated or dried.—H. H.

Buttermilk; Condensed ——, *buttermilk powder, and process for making same.* I. S. Merrell, Assr. to Merrell-Soule Co. U.S.P. 1,370,828, 8.3.21. Appl., 8.4.16.

XIXB.—WATER PURIFICATION; SANITATION.

Ice; Water softening for the manufacture of raw water ——. A. S. Behrman. J. Ind. Eng. Chem., 1921, 13, 235—237.

DISSOLVED solids and impurities in natural waters have a detrimental effect on the quality of the ice prepared from them. Calcium and magnesium compounds, present as "temporary hardness," form milky patches and bubbles, and frequently an opaque under crust, which is deposited as a sediment on melting. Permanent hardness is less objectionable, especially if magnesium compounds, which form white ice, are replaced by calcium compounds. Traces of iron give ice a reddish-brown colour; a muddy or bright yellow colour results from the presence of organic matter; and silica and alumina give the ice a muddy appearance and form a slimy sediment on melting. Sodium salts are deposited as white solids and tend to cause brittleness and cracking. During the process of freezing with air agitation most of the above solids collect as a central "core," and may to a certain extent be removed by suction pumping, followed by introduction of fresh water; this, however, involves considerable labour and expense. A satisfactory method of treatment is found in softening the water with lime; calcium chloride and sulphate retained in the water are not appreciably detrimental, and in any case less so than sodium salts; for this latter reason lime is preferable to soda ash. The objections attaching to sodium salts also render the use of zeolites for softening undesirable. —W. J. W.

Anthrax spores; Resistance of —— *to chlorine, pickling liquors, formaldehyde, and mercuric chloride.* A. Müller. Arch. Hyg., 1920, 89, 363—372. Chem. Zentr., 1921, 92, I., 501.

A 1·5% CHLORINE solution killed the spores in 8 hrs., 0·5% solution in 21 hrs. A pickle containing 0·5% of hydrochloric acid was ineffective even after 31 days, 4% hydrochloric acid solution at 37° C. killed the spores after 2 days, 2% hydrochloric acid after 6 days, 1% and 0·5% after 7 days, 0·5% formaldehyde solution killed the spores in 6 days, 5% in 5 days; 0·1% mercuric chloride solution was ineffective in 1 day, and 2% solution in 88 days. At 37° C. 0·1—5% solution of mercuric chloride killed the spores in 20—5 days.—D. W.

Sulphiformin or methanal-sulphurous acid. P. Malvezin. Bull. Assoc. Chim. Sucr., 1921, 38, 210—220.

"SULPHIFORMIN" or formaldehyde-sulphurous acid, $HO.CH_2.SO_3H$, may be prepared by acting on 40% formaldehyde solution with gaseous or dissolved sulphur dioxide, or in a more concentrated form by the interaction of gaseous sulphur dioxide with moist formaldehyde vapour in a suitable apparatus. Various reactions of the product are described, but in a footnote it is stated that the substance first formed on mixing solutions of formaldehyde and sulphurous acid is formaldehyde sulphoxylate, $HO.CH_2.SO_2H$, and this is slowly oxidised to formaldehyde-sulphurous acid. Sulphiformin is readily resolved into its components and accordingly exerts a strongly antiseptic action. A 1% solution has been employed for spraying vines, and experiments described illustrate its toxic action on yeast and bacteria.—J. H. L.

Nitrous fumes in air. Moir. *See* XXIII.

Adsorption by asbestos. Kolthoff. *See* XXIII.

PATENTS.

Water-treating apparatus. J. Roche and R. J. Parker, Assrs. to Electric Twin Water Purification Corp. U.S.P. 1,371,814, 15.3.21. Appl. 7.2.19.

AN apparatus for water treatment comprises a container which is divided into compartments by a series of perforated partitions of electrically conducting material. The compartments contain a filtering agent consisting in alternate compartments of a layer of carbon with a superposed layer of quartz and of quartz alone. Means are provided for connecting alternate partitions with the opposite poles of an electric circuit.—W. J. W.

Distilled water; Process for producing ——. B. Hilliger. G.P. 329,264, 27.5.19.

STEAM is distilled from water at less than atmo-

spheric pressure, and is condensed in a chamber surrounding the distillation vessel, whereby the latent heat evolved on condensation is utilised in heating the water remaining in the distillation vessel. The apparatus is very compact, rendering conduction and radiation losses extremely small.
—J. S. G. T.

Filter-elements. E.P. 134,228. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Yohimbine; Determination of —— in yohimbé bark. A. Schomer. Pharm. Zentralh., 1921, **62**, 169—171.

Fifteen g. of the powdered bark is shaken for 10 mins. with 150 g. of ether, 10 g. of 15% sodium hydroxide is then added, and, after 1 hr., 100 g. of the ethereal layer is drawn off and extracted with successive quantities (20, 10, and 10 c.c.) of 1% hydrochloric acid; the acid extracts are shaken with chloroform to remove impurities, then rendered alkaline with sodium carbonate solution, and extracted with chloroform. The chloroform extract is evaporated, the residue dissolved in alcohol to which is added a few drops of hydrochloric acid, the alcohol is evaporated, the residue treated with ether and evaporated, and finally warmed with 50 drops of alcohol. When most of the alcohol has evaporated 50 g. of chloroform is added, the mixture cooled at 0° C. for 30 mins., and the crystals of yohimbine hydrochloride then collected, dried at 100° C., and weighed. Three samples of bark examined yielded 0·78—1·26% of yohimbine. The crystals of the hydrochloride obtained had m.pt. 272° C., whilst pure yohimbine hydrochloride has m.pt. 285°—290° C.—W. P. S.

Humins and humic acids; Synthesis of ——. J. Marcusson. Ber., 1921, **54**, 542—545. (*Cf.* J., 1919, 350 A; 1920, 180 A.)

Furan when treated with concentrated hydrochloric acid gives a pale brown infusible resin, which is converted by fusion with potassium hydroxide into a humic acid. The course of the reaction appears to be: Furan → αδ-dihydroxydivinyl, HO.CH:CH.CH:CH.OH → succinaldehyde. The latter yields the aldol and subsequently the α-peri-difuran, which polymerises with formation of humin. The acidity of the humic acids has been ascribed by Eller and Koch (J., 1920, 717 A) to the presence of phenolic hydroxyl groups; the ready, if incomplete, esterification of these substances when heated with alcoholic hydrogen chloride (3%) and the elimination of carbon dioxide at 250° C. in the presence of superheated steam, however, indicates the presence of carboxyl groups. (*Cf.* J.C.S., May.)—H. W.

Yeast-nucleic acid. S. J. Thannhauser and P. Sachs. Z. physiol. Chem., 1920, **109**, 177—182.

No precipitate of the brucine salt of uridinephosphoric acid was obtained by shaking Böhringer's yeast-nucleic acid with water for 24 hrs., concentrating the filtrate under reduced pressure, boiling with brucine, and treatment with alcohol. It is concluded therefore that the yeast-nucleic acid does not contain free uridinephosphoric acid, and that the barium salt obtained by Steudel and Peiser by fractionating yeast-nucleic acid with barium acetate (J., 1921, 60 A) is not that of uridinephosphoric acid.

Nucleic acids of the lymphatic ganglions and of the thymus; Physiological properties of the ——. Conditions for obtaining a thymonucleic acid very active to blood. Doyon. Comptes rend., 1921, **172**, 820—821.

The ganglions of the mesentery, carefully freed from membranes and fat, when treated according to Neuman's method, yield a nucleic acid preparation, which is quite white and permits of the preparation of a very stable, limpid, colourless blood plasma. In preparing nucleic acid from the thymus of a calf, the material should be crushed, mixed with water, and allowed to putrefy for 15—18 hrs. before applying Neuman's method, and only 200—300 g. should be used. This gives a very active preparation.—W. G.

Arsphenamine [salvarsan]; Arsenical compounds related to ——. G. W. Raiziss and J. L. Gavron. J. Amer. Chem. Soc., 1921, **43**, 582—585.

The undesirable symptoms which sometimes follow intravenous injection of salvarsan are conceivably due to chemical impurities. Some of those possibly present have therefore been examined. 3.5.3′.5′-Tetramino-4.4′-dihydroxyarsenobenzene tetrahydrochloride, from the corresponding dinitrohydroxyphenylarsinic acid and sodium hydrosulphite, exerts a curative influence on trypanosome infections, and exists in two forms, one easily soluble in methyl alcohol, the other sparingly. The preparation of 3.5-diamino-4-hydroxy- and 3-amino-4-hydroxy-phenylarsinic acids (G.P. 224,953; J., 1910, 1178) and the reduction of their acetyl derivatives to arsenobenzene derivatives are described. (*Cf.* J.C.S., May.)—J. K.

Neoarsphenamine [neosalvarsan]; Chemistry of —— and its relation to toxicity. G. W. Raiziss and M. Falkov. J. Biol. Chem., 1921, **46**, 209—221.

Three commercial samples were examined, particularly as regards the distribution of the sulphur. A lower arsenic content may be due to the presence of uncombined sodium formaldehyde-sulphoxylate, sulphate, or choride. The arsenic:nitrogen ratio equals the theoretical in good samples and may be taken as an index of purity. The amount of iodine necessary for complete oxidation is in excess of that required merely by arsenic; this is attributed to uncombined sulphoxylate; sulphoxylate combined with the amino group does not react with iodine. The amount of combined sulphoxylate indicates that the samples were mixtures of mono- and di-substituted products.—G. B.

Neoarsphenamine [neosalvarsan]; Examination of ——. A. D. Macallum. J. Amer. Chem. Soc., 1921, **43**, 643—645.

The best criterion of the purity of neosalvarsan consists in the determination of the sulphoxylate group, $\cdot CH_2OSONa$, by subtracting from the total reducing power, determined by iodine, that due to free reducing substances and to arsenic, and multiplying the result by 3·9553. Details of the estimations are given, although it is not possible to obtain a product in which the ratio sulphoxylate group:arsenic is exactly 1:2, the best preparations approximate closely to this value.—J. K.

Adrenaline solutions; Preparation and preservation of ——. F. Richard and M. Malmy. J. Pharm. Chim., 1921, **23**, 209—214.

A solution which keeps well is prepared by dissolving 1 g. of adrenaline in 100 c.c. of 0·75% sodium chloride solution containing 1 g. of dissolved sulphur dioxide and then diluting the mixture to 1000 c.c. with 0·75% sodium chloride solution which has been sterilised previously.
—W. P. S.

Saccharin; Detection of ——. A correction. L. Thevenon. J. Pharm. Chim., 1921, **23**, 215.

A reaction described recently (J., 1921, 60 A) is not characteristic of saccharin, since one of the

reagents used (β-naphthol) itself yields a red coloration with nitrous acid in dilute acid solution. —W. P. S.

Aristol. G. H. Woollett. J. Amer. Chem. Soc., 1921, **43**, 553—561.

By the action of one, two, and four equivalents each of iodine and alkali hydroxide on thymol, iodothymol, a gum almost completely soluble in alcohol, and aristol are respectively obtained, and iodothymol can be converted into the other products by treatment with appropriate amounts of iodine and alkali hydroxide. Ordinary aristol is a mixture of the gum (ca.40%) with a faintly yellow product, insoluble in alcohol, resembling the leuco derivative of Lautemann's Red (Annalen, 1861, **120**, 309) in its oxidisability to a red product, $(C_{10}H_{11}IO)_n$, sparingly soluble in alcohol. The colour of fresh aristol is due, not to adsorbed iodine, but to this oxidation product, which suffers gradual reduction and liberates iodine from the gummy portion. Lautemann's Red similarly liberates iodine from iodothymol. (*Cf.* J.C.S., May.)—J. K.

Dicyanodiamide; Action of sulphuric acid on ——. T. L. Davis. J. Amer. Chem. Soc., 1921, **43**, 669—672.

It is shown that the formation of guanidine by the action of 61% sulphuric acid on dicyanodiamide is slow at 100° C., but an 85% yield is obtained after six hours at 140° C. and the yield is only slightly improved at 200° C. At the higher temperature carbon dioxide is produced in excess of that calculated, probably owing to some further hydrolysis of guanidine. (*Cf.* J.C.S., May).—J. K.

Perchloromethylmercaptan. O. B. Helfrich and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 591—594. (*Cf.* Frankland and others, J., 1920, 256 T).

Perchloromethylmercaptan is best obtained by chlorinating carbon bisulphide at 20°—30° C. in diffused light in presence of 0·3—0·4% of iodine until its volume is doubled. Sunlight, a temperature above 30° C., and over-chlorination favour production of carbon tetrachloride, and no other "carrier" than iodine is suitable. By reduction with iron and hydrochloric acid, thiophosgene and carbon tetrachloride are obtained, and the latter is the sole product of boiling the compound with iron alone. Zinc and hydrochloric acid apparently convert it into methane. (*Cf.* J.C.S., May.)—J. K.

Nitrotartaric acid. A. Lachman. J. Amer. Chem. Soc., 1921, **43**, 577—581.

Nitrotartaric acid is the dinitrate of tartaric acid, $CO_2H.CH(ONO_2).CH(ONO_2).CO_2H$, since it yields by hydrolysis with fairly concentrated mineral acid nitric and tartaric acids, but with water alone gives rise to nitrous and dihydroxytartaric acids, with some tartronic and oxalic acids, whilst the last two are the only organic acids produced in presence of alkali. In explanation of these reactions, it is suggested that the acid reacts in a pseudo-form, $CO_2H.C(OH)(ONO).C(OH)(ONO).CO_2H$. Although the moist acid decomposes with some violence below 100°, it is stable at the boiling point of xylene when dry. (*Cf.* J.C.S., May.)—J. K.

[Organic] acids; Identification of ——. VI. Separation of acids by means of phenacyl esters. J. B. Rather and E. E. Reid. J. Amer. Chem. Soc., 1921, 43, 629—636.

A number of illustrations, chosen from naturally occurring organic acids, are given to show that the constituents of a mixture of such acids may frequently be identified by preparation of their phenacyl esters from the sodium salts (J., 1920, 501 A), followed by fractional crystallisation.—J. K.

Alkylamines; Detection of volatile —— in the presence of ammonia and volatile tertiary alkylamines in the presence of volatile primary and secondary alkylamines. H. E. Woodward and C. L. Alsberg. J. Biol. Chem., 1921, **46**, 1—7.

Incipient decomposition of foodstuffs may be recognised by the presence of traces of amines, which are, however, difficult to distinguish from the ammonia also present. In dilute alkaline solution ammonia reacts with formaldehyde to form hexamethylenetetramine, but methylamines (*e.g.*, 10 c.c. of 0·01—0·02 *N* amine distilled into 1 c.c. of 40% formaldehyde) furnish methyl alcohol and formic acid. The formic acid is detected by a solution containing 180 g. of mercuric bromide and 120 g. of potassium bromide per litre, which gives on warming a white precipitate of mercurous bromide, when a quantity of formic acid corresponding to 0·5 mg. of amine nitrogen is present. Ammonia, mono- and dimethylamine also give a white precipitate with mercuric bromide, but this is soluble in excess of formaldehyde. Trimethyl and triethylamine form with potassium mercuric iodide (450 g. HgI_2 and 330 g. KI per litre), yellow crystalline compounds melting at 136° and 77° C. respectively, if excess of potassium iodide be avoided. Trimethylamine is still precipitated at 3 mg. in 5 c.c.; dimethylamine requires to be at least six times as concentrated. At suitable concentrations the tertiary amine only is precipitated, and then may be obtained pure by distilling the mercuric iodide compound with sodium hydroxide and sulphide.—G. B.

Catalytic hydrogenations over copper. P. Sabatier and B. Kubota. Comptes rend., 1921, **172**, 733—736.

The catalyst is prepared by slowly reducing black tetracupric hydroxide at 200° C. When benzaldehyde and hydrogen are passed over this catalyst at 350° C. the main products are benzene and carbon monoxide, together with some toluene. Under similar conditions acetophenone yields ethylbenzene, and ethyl phenyl ketone yields propylbenzene. Benzoylpropanone is, however, decomposed, giving acetophenone, acetaldehyde, ethyl alcohol, and a little ethylbenzene. Benzoquinone gives almost exclusively quinol. Phthalic anhydride at first yields benzene and carbon monoxide, but soon the action changes and phthalide is formed, together with some toluene and carbon monoxide as products of an accessory change.—W. G.

Catalysts; Influencing of —— and specifically active catalysts. K. W. Rosenmund and F. Zetzsche. Ber., 1921, **54**, 425—437.

The catalytic reduction of acid chlorides to aldehydes (J., 1918, 442 A) by means of hydrogen in the presence of palladinised barium sulphate is somewhat uncertain, and the effect of a large number of substances on the conversion of benzoyl chloride into benzaldehyde in benzene, toluene, and cumene solution has therefore been investigated. With pure materials, practically no aldehyde is formed; the most effective addition is "sulphured" quinoline (quinoline boiled under a reflux condenser for 5—7 hrs. with one-sixth of its weight of sulphur); specimens of the latter which have been used previously appear to be even better reagents than the freshly-prepared material, the yields reaching 88%. Under similar conditions, *o*-chlorobenzoyl chloride gives *o*-chlorobenzaldehyde (more than 70%), *p*-nitrobenzoyl chloride yields *p*-nitrobenzaldehyde (91%), and phenylacetyl chloride is converted into phenylacetaldehyde (80%). This appears to be the first recorded instance in which a specific catalyst

has been artificially produced by the addition of a chemically well-defined substance. (*Cf.* J.C.S., May.)—H. W.

Halogen united to nuclear carbon and its replacement by other substituents. III. Preparation of arsinic and sulphonic acids. K. W. Rosenmund. Ber., 1921, **54**, 438—440.

PHENYLARSINIC acid is obtained in small yield when bromobenzene, normal potassium arsenite, water, and copper sulphate are heated at 180°—200° C. Similarly, potassium *o*-bromobenzoate, potassium arsenite, copper powder, and aqueous alcohol give *o*-carboxyphenylarsinic acid at about 90° C. Benzenesulphonic acid is prepared from bromobenzene, sodium sulphite, and copper sulphate in the presence of water at 180° C., and subsequently at 200° C. Similarly, *p*-bromotoluene gives toluene-*p*-sulphonic acid. Sodium *o*-bromobenzoate and sodium sulphite in like manner yield *o*-sulphobenzoic acid at 120°—130° C., or when boiled under a reflux condenser. *m*-Sulphobenzoic acid is prepared from *m*-bromobenzoic acid at 170°—180° C. —H. W.

Cyanic acid; Synthesis of —— by oxidation of organic substances. New methods of detecting this substance. R. Fosse. Bull. Soc. Chim., 1921, **29**, 158—203.

A *résumé* of work already published (*cf.* J., 1919, 655 A; 1920, 747 A, 781 A).—W. G.

N-Butyl alcohol and water; Specific gravities of mixtures of ——. Y. D. Wad and A. G. Gokhale. J. Ind. Inst. Sci., 1921, **4**, 17—25.

THE specific gravities of mixtures of *n*-butyl alcohol and water covering the entire range of miscibility were determined at temperatures of 20° and 25° C., and from the results curves were made and tables are given showing the specific gravities of aqueous butyl alcohol of all concentrations, from which the following figures are taken:—

% Water.	Sp. gr. at 20° C.	Sp. gr. at 25° C.	% Water.	Sp. gr. at 20° C.	Sp. gr. at 25° C.
0·0	0·8096	0·8066	18·5	0·8448	—

—G. F. M.

Aliphatic alcohols; Purification and some physical properties of certain ——. R. F. Brunel, J. L. Crenshaw, and E. Tobin. J. Amer. Chem. Soc., 1921, **43**, 561—577.

OWING to their hygroscopic nature it was not found possible to obtain satisfactorily exact boiling points of the alcohols tested, except in presence of drying agents. Of these aluminium amalgam (J., 1895, 898) was the most satisfactory owing to the rapidity of its action; lime and baryta were ultimately equally effective, but metallic calcium, whilst speedy in its action, is not as valuable for this purpose, possibly owing to the presence of an impurity. Boiling points, densities, and refractivities of a number of alcohols are recorded (*cf.* J.C.S., May).—J. K.

Methyl alcohol; Process for the purification of ——. A. Lanzenberg and J. Duclaux. Bull. Soc. Chim., 1921, **29**, 135—136.

COMMERCIAL methyl alcohol usually contains appreciable amounts of acetone in addition to other impurities of higher boiling point. For its purification 1 pt. of alcohol is mixed with 7·5 pts. of chloroform, the mixture distilled, and the fraction boiling at 52·5°—53·5° C. collected. From this fraction the alcohol is extracted with water, the aqueous alcohol being subsequently distilled and rectified in the usual manner.—W. G.

Pepsin. Brewster. *See* XIXA.

PATENTS.

Immunising serum; Process for purifying and enriching ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 104,688, 7.3.17. Conv., 7.3.16.

SERUM which has been freed from euglobulin and electrolytes, preferably by an electro-osmotic process, is placed in the middle chamber of a three-cell electrolytic apparatus; the anodic diaphragm consists of an animal substance, such as hide or bladder, which behaves positively, and the cathodic diaphragm of a vegetable material, such as parchment paper, which behaves negatively to the electric current. The albumins migrate to the anode chamber, whilst the fatty substances separate in the middle chamber. The serum obtained is clear and may be evaporated under reduced pressure to dryness or to any desired concentration. The electric current is applied preferably at high tension and by previous treatment with a relatively low tension it is possible to eliminate the mineral constituents and globulins in the same apparatus.—D. F. T.

Dialkyl sulphates; Manufacture of ——. L. Lilienfeld. E.P. 143,260, 14.5.20. Conv., 15.12.13.

DIALKYL sulphates are prepared by the direct action of sulphur trioxide on aliphatic alcohols in presence of dehydrating agents, such as phosphorus pentoxide or anhydrous sodium sulphate or copper sulphate, and in presence or absence of inert diluents, such as chloroform, carbon tetrachloride, and the like.—J. H. L.

Caffeine; Extraction of —— from coffee beans. H. C. E. Lombaers. E.P. 144,998, 19.3.20. Conv., 13.6.19.

IN order to avoid condensation of steam and consequent depreciation of the coffee beans during the preliminary "opening up" before the removal of caffeine, the beans are previously raised to the steam temperature. The subsequent steam treatment occupies about 3 hrs., and causes no loss of the valuable extractable and aromatic constituents. After the extraction of the caffeine the beans are again heated before the application of steam for the removal of the extraction agent.—D. F. T.

Methane; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 146,114, 22.6.20. Conv., 1.7.19. Addn. to 146,110 (J., 1921, 26 A).

IN the catalytic reduction of carbon monoxide to methane by means of hydrogen, a product of greater purity and free from hydrogen and carbon monoxide is obtained by using carbon dioxide in the later stages of the reaction in the proportion of somewhat more than 1 vol. to every 4 vols. of hydrogen present. Nearly all the hydrogen is thereby converted into methane and water, the latter being periodically separated, whereas with carbon monoxide deposition of carbon commences when the proportion of hydrogen is allowed to become less than 5 vols. for every vol. of monoxide present. The excess of carbon dioxide is finally removed from the product by absorption by lime or other means, and traces of hydrogen by passing over heated copper oxide.—G. F. M.

Tobacco; Process for the treatment of ——. O. Braemer. E.P. 160,128, 25.10.20.

TOBACCO is impregnated with a solution of caffeine. —D. F. T.

1-Methyl-2-amino-4-isopropyl-5-nitrobenzene. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,923, 2.9.19. Appl., 22.9.17.

CYMENE is treated with a mixture of sulphuric and nitric acids and the nitrocymene reduced to 1-methyl-2-amino-4-isopropylbenzene. This is converted into the 2-acetamino derivative, which on nitration and hydrolysis yields 1-methyl-2-amino-4-isopropyl-5-nitrobenzene, or, if reduced before hydrolysis, the 2.5-diamino compound.

Dimethyl-di-isopropylbenzidine and process of making same. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,924, 2.9.19. Appl., 15.9.17.

CRUDE mononitrocymene is reduced in alkaline solution to hydrazocymene, which when subjected to the benzidine transformation (treatment with hydrochloric acid) is converted into dimethyl-di-isopropylbenzidine, b.p. 250° C.

Methyl-amino-isopropylbenzenesulphonic acid and process of making same. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,927, 2.9.19. Appl., 14.9.17.

AMINOCYMENE is heated with 98% sulphuric acid for 10 hrs. at about 200° C., the product is neutralised with alkali, boiled with charcoal, and precipitated with acid. 1-Methyl-2-amino-4-isopropylbenzene-5-sulphonic acid is obtained.

Arsenical compound. W. A. Jacobs, W. H. Brown, M. Heidelberger, and L. Pearce, Assrs. to Rockefeller Institute for Medical Research. U.S.P. 1,315,127, 2.9.19. Appl., 13.6.18.

A SOLUTION of N-(arsenoaryl)bis-α-aminoacylarylamines (U.S.P. 1,280,123; J., 1919, 268 A) in an alkali hydroxide is evaporated under reduced pressure or precipitated with alcohol to produce alkali salts of, *e.g.*, N-(*p*-arsenophenyl)bis-glycyl-*m'*-aminophenol,

$$MO.C_6H_4.NH.CO.CH_2.NH.C_6H_4.As{:}$$
$$As.C_6H_4.NH.CH_2.CO.NH.C_6H_4.OM,$$

which are of value in trypanosomal or spirochætal diseases.

Organic substances; Process for electrolytic treatment of —— without the use of a diaphragm. Farbenfabr. vorm. F. Bayer und Co. G.P. 310,023, 20.10.16.

THE electrolyte is made up of liquids of different density, one of which contains the organic substance to be treated in solution. Means are provided to prevent the gases liberated at the opposite pole from coming into contact with the liquid containing the substance undergoing treatment. The method may be used for the preparation of piperidine from pyridine and of pinacone from acetone.—A. R. P.

Organic compounds; Production of —— from compounds containing a smaller percentage of hydrogen. C. Neuberg, A., K., and R. Welde, and E. Heisler. G.P. 330,812, 21.3.14.

REDUCTION of organic compounds, *e.g.*, benzaldehyde to benzyl alcohol, nitrobenzene to aniline, aldol to butyleneglycol, nitromethane or nitroethane to methyl- or ethylamine, or quinone to quinol, is effected by the addition of yeast preparations, or a fermenting mixture of yeast and sugar solution, to the compounds. When reduction is complete, the product is isolated from the mixture. —L. A. C.

Double salt of glycerophosphoric and lactic acids; Process for the preparation of a ——. E. Merck, Chem. Fabr., and L. Weber. G.P. 331,695, 14.4.20.

CALCIUM or ferric glycerophosphate is allowed to react with the corresponding lactate, and the resulting dark red-brown solution is evaporated at a low temperature to recover the readily soluble double salt. The solutions on boiling do not deposit either calcium or ferric glycerophosphate.—A. R. P.

Chlorides of aromatic carboxylic acids; Process for the preparation of ——. Badische Anilin- und Soda-Fabr. G.P. 331,696, 17.7.14.

GOOD yields of aromatic acid chlorides are obtained by heating the corresponding trichloride (1 mol.) with water (1 mol.) in the presence of concentrated sulphuric acid and ferric chloride as catalysts. Thus benzotrichloride yields benzoyl chloride, and 2.4-dichlorobenzotrichloride yields 2.4-dichlorobenzoyl chloride as a colourless oil boiling at 152°—155° C. under 30 mm. pressure.—A. R. P.

Albumins; Combination of metals with ——. K. Kottmann, Assr. to Society of Chemical Industry in Basle. U.S.P. 1,371,380–1, 15.3.21. Appl., 27.9.16 and 26. 5.17.

SEE E.P. 110,936 and 115,686; J., 1917, 1289; 1918, 442 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic density, light intensity, and exposure time; Relation between ——. F. E. Ross. Communication No. 93 from Research Lab. of Eastman Kodak Co. J. Opt. Soc. Amer., 1920, 4, 255—273.

THE formulæ previously suggested by Abney, Hurter and Driffield (J., 1890, 455), Elder, and Channon to express the relation between exposure and image density are examined mathematically and as to their agreement with the experimental values for two emulsions of different type, the one (A) having a high development factor and a short foot, the other (B) having a low development factor and a long foot. Each one is shown to fail on some theoretical consideration and shows also appreciable discrepancy between calculation and experiment, which is more marked with emulsion A than with emulsion B. Taking as the simplest assumptions warranted by available data that the sensitive grains of a plate may be divided into n groups, each having the same silver content and increasing in sensitiveness by the constant factor, r, and that each group as a whole obeys the mass action law, the formula deduced is

$$D = d_m \left[1 - \frac{1}{n} \sum_{S=0}^{S=n-1} e^{-\kappa r^S I t} \right]$$

where d_m is the maximum density obtainable, κ is the sensitivity factor, r the common ratio of the sensitivities of the various groups, I the acting intensity, and t the exposure time. The method for determining the various constants is developed and calculated compared with experimental values for plates A and B as before; agreement is close for B but not for A. The equations suggested by Schwarschild [$I\ t^p = C$] and by Kron

$$(\phi = t.I.10^{-\frac{a}{2}\sqrt{(\log I/I_0)^2+1}})$$

to express the relation between I and t for equal effects on a photographic plate (which does not obey the reciprocity law), are discussed mathematically and some pecularities deduced which necessitate further experimental work. Assuming Schwarzschild's expression to hold, a method is deduced for determining p from the values obtained for the development factors for a time scale and an intensity scale exposure.—B. V. S.

Grain size and sensitometric properties of [photographic] emulsions. E. P. Wightman and S. E. Sheppard. Brit. J. Phot., 1921, **68**, 169—172.

This is chiefly a discussion and comparison of papers by Ross (*cf. supra*), Slade and Higson (J., 1921, 27 A), Svedberg (J., 1920, 705 A), and Higson (J., 1921, 98 A). Higson's suggestion that the size of a developed grain is approximately four times that of an undeveloped grain is shown to be inconsistent with data taken from his own and Svedberg's work.—B. V. S.

"Photographic plate; Action of light on the ——," and "The photochemical law of the silver halide grain": a criticism. L. Silberstein and S. E. Sheppard. Phot. J., 1921, **61**, 205—206.

Objection is raised to the conclusion, in the paper by Slade and Higson (J., 1921, 27 A) on which that of Higson (J., 1921, 98 A) is based, that light is not absorbed in quanta by the photographic plate; the statement is based on the observed fact that the rate of conversion of silver bromide grains to the developable condition is not proportional to the light intensity and to the number of grains still unchanged, a fact which has no reference to the quantum theory. It is pointed out that after defining "P," the probability of any grain becoming developable in unit time, from the equation $dx/dt = P(a-x)$, it is assumed that P is a function of only I and t and not of x. Further it is stated that the method of arriving at the complete law for the photographic plate by multiplying together the two functions obtained by consideration of the cases when I is variable and t constant and when t is variable and I constant, is mathematically invalid, and the resulting equation is not therefore justified. Other minor criticisms are also put forward.
—B. V. S.

Colloid chemistry and photography. LII. Acceleration of development by dyes and neutral salts. Lüppo-Cramer. Kolloid-Zeits., 1921, **28**, 174—175.

The accelerating effect of certain basic dyestuffs on alkaline developers, notably that of Phenosafranine on quinol, has its analogue in a recently observed accelerating effect of certain acid dyes on acid (physical) developers. Thus plates bathed in Erythrosin solution and developed in an acid silver-amidol bath show quicker development; it is preferable, as in all cases of physical development, to treat the plates, before development, in iodide solution which opens up the grain ("lays bare the exposure germ"). Phenosafranine under the same conditions gives a reduction of speed of development. Physical developers are also quickened by addition in considerable concentration of neutral salts such as potassium nitrate and sodium sulphate.
—B. V. S.

High-speed radiography and radiometallography. T. Thorne-Baker and L. A. Levy. Phot. J., 1921, **61**, 158—166.

By coating a plate first with a special type of light-sensitive emulsion and then with a solution of gelatin containing calcium tungstate in suspension, a composite plate of very high speed to X-rays is obtained. The silver bromide emulsion has as nearly as possible a spectral sensitiveness corresponding with the fluorescence produced by calcium tungstate when excited by X-rays, the spectrograph of which shows maxima at $\lambda = 24$ to $25\mu\mu$, $31\mu\mu$, and $48\mu\mu$ respectively. The ultra-violet sensitiveness is particularly high and the plate is liable to fog in development when using dark room light filters which are not completely opaque to ultra-violet. The gelatin for the emulsion is specially hardened to stand soaking in water at 115°—120° F. (46°—49° C.) without softening. The calcium tungstate for the upper film is prepared as an amorphous powder by precipitation, then carefully purified, treated with a very small quantity of impurity, and heated to 1000° C. in a carefully controlled electric furnace. The fine crystals which are thus produced are graded, the medium sized ones, having a diameter a little less than that of ordinary silver-bromide plate grains, being used. The calcium tungstate is applied to the light-sensitive film in a solution of a very soft gelatin which easily dissolves in water at 100° F. (38° C.). The coating conditions are such that the grains of tungstate settle into close contact with the sensitive film, thus giving maximum efficiency and enabling a small quantity of salt so applied to have as great an intensifying effect as the much larger quantity required for an ordinary intensifying screen. In use the plates after exposure are placed in water at about 105° F. (40° C.) which softens and washes away the upper film, the plate being then developed in the usual way, but preferably with an increase of concentration of the developer because of the lower permeability of the film. A hard X-ray tube gives better results and shorter exposures than a soft tube, the full advantage as to speed being obtained with the former only. For this reason the plates are also particularly suitable for radio-metallography.—B. V. S.

Pinaflavol, a new [photographic] sensitiser for green. J. M. Eder. Phot. Korr., 1921, **58**, 29—31. E. König. Phot. Runds. Brit. J. Phot., 1921, **68**, Col. Suppl., 16.

Pinaflavol (M., L., and B) is one of a new class of basic yellow dyes which are soluble in water and, like Pinacyanol, are stable towards acetic acid but are decolorised by mineral acids. Applied to the photographic plate either by addition to the emulsion or by bathing, Pinaflavol confers a marked sensitiveness in the green and yellow, extending to the D line and practically without the gap in the blue-green shown by plates sensitised by Erythrosin. In three-colour work Pinaflavol plates have the advantage over Pinaverdol plates, in that the relatively sharp ending of the spectral sensitiveness in the yellow enables their use for exposure to green light behind a yellow screen instead of behind a green screen; exposures are considerably reduced because of the greater transparency to green of yellow dyes.—B. V. S.

Desensitisers. E. König and Lüppo-Cramer. Phot. Runds., 1921, 37—38.

Dyestuffs of other classes than the Safranine group (*cf.* J., 1921, 99 A), containing several amino groups, *e.g.*, Chrysoïdine, are somewhat active as desensitisers; those with only one amino group, such as Congo Red, are quite without action. The replacement of the hydrogen of the amino group by methyl has no effect on the desensitising power.
—B. V. S.

Desensitisers; New application of ——. (Handling of X-ray plates in yellow light without use of a preliminary bath and without addition to the developer). Lüppo-Cramer. Phot. Korr., 1921, **58**, 40—43.

X-ray plates treated with Phenosafranine or similar desensitiser have their sensitiveness to light reduced much more than that to X-rays. This is explained as being due to the fact that light action occurs only on the surface of the silver bromide grains which is protected in the desensitising process by deposition of the dye, while the action of X-rays occurs throughout the whole grain, the interior of which is not protected by dye deposition. After a treatment with Phenosafranine (1/20000), measurements by E. Mauz showed a reduction of X-ray sensitiveness of 25 to 30% in the neighbourhood of the threshold density values, but practically

no reduction in the more exposed parts, while the reduction of light sensitiveness permitted development by a strong light.—B. V. S.

Desensitising—an oxidation process. Lüppo-Cramer. Phot. Ind., 1921, 259.

It is suggested that the action of desensitisers is an oxidising action on the latent image, which is bleached if exposed to light in the presence of certain desensitising dyes. Plates which are uniformly exposed, then dyed and then exposed to a subject, give reversed images showing definite sensitiveness. If silver bromide diapositive plates are exposed, converted into iodide, and then stained, the silver iodide complex is strongly colour-sensitive.—B. V. S.

Colour-toning and negative intensification; The mordant dye process for ——. F. E. Ives. Brit. J. Phot., 1921, **68**, 186—187.

The mordant dye process previously described (*cf.* J., 1921, 99 A) for the production of three-colour transparencies is adaptable to the toning of prints on glass or celluloid but not on paper. The bleaching bath recommended is potassium ferricyanide 5 pts., ammonium bichromate 1 pt., glacial acetic acid 110 pts., and water 13,000 pts. The print is placed dry in the bleaching bath for ½ to 2 mins., no bleaching action being visible, washed for about 5 mins., and transferred to the dye bath. Suitable dyes are Malachite Green, Safranine, Phenosafranine, Rhodamine, and Auramine, made up to a strength of about 1:17000 in water slightly acidified with acetic acid. The process is also adaptable to negative intensification if suitable non-actinic colours are selected, for which purpose a mixture of Victoria Green and Safranine is recommended.
—B. V. S.

Silver removal process; New photographic ——. A. Steigmann. Kolloid-Zeits., 1921, **28**, 175—176.

Silver is removed, easily and completely, as the metal, in comparatively pure state, from silver solutions such as used "hypo" baths by the use of hydrosulphite. A litre of used "hypo" requires 6—8 g. of hydrosulphite and about the same quantity of caustic soda, about 4 g. of metallic silver being precipitated. It is preferable to work at 50°—60° C. "Hypo" baths so treated may be used again, since the oxidation of hydrosulphite results in the formation of sulphite and thiosulphate.
—B. V. S.

Photographic registration of chemical reactions. Jolibois. *See* XXIII.

PATENTS.

Coloured pictures; Process for making ——. A. Traube. E.P. 147,005, 6.7.20. Conv., 1.2.16.

A picture consisting of a silver image which has been copper-toned (converted to mixed silver-copper ferrocyanide) is further toned by treatment with a solution of a basic dyestuff, about 5 mins. in a dye bath of 1/1000 strength being generally sufficient; the excess of dye is removed from the gelatin by a short washing in water. The transparency of the dyed copper picture is very high and may be still further increased by the removal of the silver ferrocyanide contained in it by treatment with a weak soda fixing solution. A large number of basic dyes are suitable for use in this process, so that almost any desired tone can be obtained.—B. V. S.

Photographic developer and method of developing latent images. A. S. McDaniel and A. H. Nietz, Assrs. to Eastman Kodak Co. U.S.P. 1,370,896, 8.3.21. Appl., 10.4.17. Renewed 4.9.20.

Diaminophenolsulphonic acid, in alkaline solution, is used as a photographic developer.
—B. V. S.

Photographic film. P. C. Seel, H. Combs, and R. Kemp, Assrs. to Eastman Kodak Co. U.S.P. 1,370,922, 8.3.21. Appl. 10.5.20.

A film of nitrocellulose containing aliphatic alcohols with four or five carbon atoms and castor oil to increase the flexibility is provided with a substratum coating before application of the sensitised coating.—B. V. S.

Negative tracing paper [blue print paper]; Process for improving the keeping quality of ——. E. Merck, Chem. Fabr., and L. Weber. G.P. 331,745, 10.2.20.

An indifferent salt, such as acid ammonium oxalate or acid ammonium phosphate, which is neither light-sensitive nor produced as a consequence of the reactions following light exposure, is added to the sensitising ferric oxalate preparation.—B. V. S.

Photographic material; Colour-sensitised ——. F. F. Renwick and O. Bloch, Assrs. to Ilford, Ltd. U.S.P. 1,372,548, 22.3.21. Appl., 21.11.18.

See E.P. 133,770 of 1918; J., 1919, 926 A.

XXII.—EXPLOSIVES; MATCHES.

Detonation; Transmission of ——. E. Kayser. Z. ges. Schiess- u. Sprengstoffw., 1921, **16**, 9—10, 25—27, 33—35.

In tests for determining the transmission of detonation by air or various solid surfaces, the following results were obtained with a safety explosive consisting of ammonium nitrate, 81%; trinitrotoluene, 17%; and flour, 2%: in air, 6 cm.; on hard ground, 7½ cm.; on a 10 mm. iron plate, 8 cm.; on loose sand, 8½ cm.; and in an iron tube of 37 mm. int. diam. and 2·5 mm. thickness, buried in the ground, 60 cm. The influence of the position of the detonator in the charge was illustrated by firing three charges in which the detonator was placed at the end remote from the test charge, in the centre, and at the end adjacent to the test charge, respectively; detonation was communicated at distances of 7, 5, and 3 cm. Although detonators do not transmit the detonation shock beyond ½ cm., their own sensitiveness to detonation was evidenced by placing them concentrically at different distances from a vertical cartridge with their open ends towards it; positive results were obtained at a distance of 66 cm. The application of the formula $d=m\sqrt{P}$ (d is the distance through which detonation is transmitted, P is the mass of the explosive, and m is a constant) for measuring the intensity of transmitted shock in the case of cartridges used in practice was investigated in eleven tests each with cartridges of different dimensions and weights. The distance through which transmission is effective, measured from the centre of gravity of the cartridge, is proportional to the length and diameter of the charge. The average value for m was found to be 1·230. Although reduction of sensitiveness of an explosive both to the initial detonation impulse and to mechanical shock is accompanied by reduced power of transmission, increased sensitiveness does not necessarily imply readier detonation or improved propagation. Thus, addition of charcoal to ammonium nitrate and TNT explosives, or of calcium silicide to ammonium nitrate and dinitronaphthalene explosives, increases the sensitiveness to the falling weight, but causes increased inertness to detonation and reduces the distance through which the detonation shock is transmitted.—W. J. W.

Potassium chlorate. Wolcott. *See* VII.

Patents.

Explosives. E. von Herz. E.P. 145,791, 2.7.20. Conv., 25.1.19.

Cyclotrimethylenetrinitramine prepared by nitration of a cyclotrimethylenetriamine derivative, specially hexamethylenetetramine or cyclotrimethylenetrimethyltriamine, is a white, crystalline powder, m.p. 200° C., sp. gr. 1·82, insoluble in water, slightly soluble in alcohol, and more readily soluble in acetone and glacial acetic acid. It is stated to have exceptionally marked explosive properties, whilst being at the same time non-sensitive to shock and friction, and stable even at high temperatures. Its velocity of detonation at maximum density is 8500 m.p.s.; heat of explosion, 1597 cals. per kg.; volume of gas liberated, 905 l. per kg. Either alone, or mixed with other explosives or constituents, it may be used for bursting charges for projectiles, for blasting purposes, or in detonators and fuses.—W. J. W.

Explosives; Process of producing desensitised —— and products thereof. K. A. Gillespie, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,370,015, 1.3.21. Appl., 3.6.18.

An explosive contains undried nitrostarch which is desensitised by the presence of water and an oil. —W. J. W.

Explosive, and process of making explosives. J. Barab, Assr. to The Commercial Research Co. U.S.P. 1,371,215, 15.3.21. Appl., 14.7.17.

A liquid explosive, which is insensitive to friction, consists of an olefine glycol dinitrate.—W. J. W.

Fertilisers from ammonium nitrate explosives. G.P. 329,960. *See* XVI.

XXIII.—ANALYSIS.

Platinum resistance thermometers and immersion heating coils of low lag; Construction of ——. T. S. Sligh, jun. J. Amer. Chem. Soc., 1921, 43, 470—475.

Changes in the construction of the strain-free type of platinum resistance thermometer from that described in U.S. Bureau of Standards Bull. **6**, 150 (J., 1910, 205), consist in the sealing of the thermometer tube to prevent condensation of atmospheric moisture in the thermometer at low temperatures, the use of a simpler thermometer head composed of a brass shell with bakelite base and cap, and the use of thermometer leads consisting of a 4-strand cable insulated with a double silk wrapping and a silk braid, each strand consisting of three No. 28 insulated copper wires twisted together and covered with silk. Calorimetric thermometers of the type described in Bull. **9**, p. 483 (1913), have been found to show low values of the δ constant in the Callendar difference formula, leading to slight errors in calibration. This is due to a strained winding. The strain may be avoided by thoroughly annealing before winding the coil, careful winding and flash-annealing afterwards. The δ value of commercial thermometers can be raised from 1·44 to 1·50 by flash-annealing without opening the thermometer case. An all-metal thermometer case of German silver is described, and also a convenient type of heating coil for laboratory use, made by winding resistance ribbon on a flat strip of mica, insulated by means of thin mica side plates, and enclosed in a flattened copper tube or sheath.—E. H. R.

Simmance total-heat recording calorimeter; Report on the ——. **T. Gray and A. Blackie.** Fuel Research Board, Tech. Paper No. 2, 1921, 23 pages.

For a period of five months a Simmance total-heat recording calorimeter was supplied with town gas, and the readings of the recorder compared with the value of the calorific power of the gas as determined by means of the calorimeter forming part of the instrument. Occasional adjustments of the recorder pen were made, and it was found that the recorded values usually differed from the directly determined values by less than 10 B.Th.U. and seldom by as much as 15 B.Th.U. On two occasions when a greater difference than this occurred, the discrepancy was traced to the accumulation of oxidised metal on the top of the gauze of the burner. The calorimeter was later supplied with various mixtures of coal gas, water-gas, and hydrogen ranging in sp. gr. (air=1) from 0·303 to 0·528, and in calorific value from 326 B.Th.U. to 514 B.Th.U. The greatest difference between the recorded calorific value and that determined by an independent calorimeter was 16 B.Th.U. With the calorimeter run on homogeneous gas, periodic variations occurring at intervals of about an hour were observed, and were due to the accumulation and subsequent sudden removal of air bubbles in the water circuit of the calorimeter. Occasional irregularities of the order of 20 B.Th.U. were attributable to restriction of the water flow by particles of rust etc. Experiments made in order to ascertain the origin of regular differences of the order ±10 B.Th.U. showed that the variations of recorded calorific values were roughly parallel with the variations in the gas factor for correcting the gas volume to 60° F. and 30″ pressure; that the rate of flow of gas through the meter varied proportionately with the gas factor, and that the claim that the gravity meter automatically corrects the flow of gas for varying pressure and density is substantially true; that variations of the external temperature caused a variation of the recorded calorific value amounting to ±1·4 B.Th.U. per ±1°F.; and that owing to the change of viscosity of water with temperature, a change of ±1° F. in the water supply produces a total effect on the recorder reading amounting in some cases to nearly ±1%.—J. S. G. T.

Photometric methods and apparatus for the study of colloids. S. E. Sheppard and F. A. Elliott. J. Amer. Chem. Soc., 1921, 43, 531—539.

Two types of photometer, distinguished as vertical and horizontal types, for the study of colloids, are described. The vertical type can be modified for use as a nephelometer, colorimeter, microphotometer, dispersimeter, or turbidimeter. The horizontal type is a transmission and scatter photometer, chiefly of use for determining size of particles, comparative turbidities, and coagulation velocities.—E. H. R.

Photographic registration of chemical reactions accompanied by a variation of pressure; Method of ——. P. Jolibois. Comptes rend., 1921, 172, 809—811.

The apparatus, which is figured and described, is a simple adaptation of the double galvanometer of Le Chatelier and Saladin for the measurement of pressures in function of temperatures. It permits of the registration in one operation of the vapour pressure of a substance or the dissociation pressure of a compound. Velocities of reaction can be compared and, for a given velocity of heating, the temperature at which a reaction assumes an appreciable velocity can be determined.—W. G.

Adsorption; Importance of —— in analytical chemistry. VIII. Adsorption by asbestos. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 401—407.

IMPURE asbestos adsorbs positive ions in accordance with the adsorption law. Lead especially is readily adsorbed from dilute solutions, being afterwards easily removed by means of acids; this may be made the basis of a method for the estimation of lead in drinking water. Impure asbestos should be made suitable for analytical work by repeated extraction with acid. (*Cf.* J.C.S., May.)—S. I. L.

Potash [; Perchlorate method for the determination of ——]. T. D. Jarrell. J. Assoc. Off. Agric. Chem., 1920, **3**, 315—321.

THE perchlorate method is accurate and, if a sufficient quantity of perchloric acid is used, the results obtained are not influenced by the presence of phosphates and sodium, magnesium, and calcium salts. Sulphates and ammonia must be removed before the perchloric acid is added. After the potassium salts have been extracted from mixed fertilisers with hot water, the addition of ammonia and calcium oxalate is unnecessary.—W. P. S.

Calcium group; Simplified methods of analysis in the —— . E. Ludwig and H. Spirescu. Bul. Soc. Chim. România, 1920, **2**, 35—37.

STRONTIUM is in every case detected by the flame test. After precipitation of the metals of the group with ammonium carbonate in the presence of ammonium chloride the filtrate will contain sufficient calcium and barium, if these elements are present, to permit of their detection with ammonium oxalate and sulphuric acid respectively. Alternatively ammonium oxalate is used as the group precipitant. The filtrate will then contain sufficient barium for its detection with sulphuric acid, and calcium may be detected microchemically in the precipitate by treatment with sulphuric acid. (*Cf.* Behrens-Kley, Microchem. Analyse, 1915.)
—W. G.

Calcium and magnesium; Determination of —— in different saline solutions. E. Canals. Bull. Soc. Chim., 1921, **29**, 152—158. (*Cf.* J., 1920, 283 A, 706 A.)

MAGNESIUM is not precipitated as oxalate along with calcium oxalate if the dilution of the magnesium ion is greater than 1%. Any magnesium which is precipitated, owing to higher concentrations, may be removed by repeated washing with boiling water, it being necessary in some cases to use 500 c.c. of water.—W. G.

Ferric, aluminium and chromium hydroxides; New method for the separation of ——. M. and M. Lemarchands. Ann. Chim. Analyt., 1921, **3**, 86—87.

A MIXTURE of the freshly-precipitated hydroxides is washed until free from ammonia, and then boiled with 10% sodium hydroxide solution to which sodium perborate is added; the chromium and aluminium hydroxides dissolve as sodium aluminate and sodium chromate, respectively, whilst the ferric hydroxide remains insoluble. The latter is separated by filtration; on boiling a portion of the filtrate with the addition of an excess of ammonium chloride, the aluminium hydroxide is re-precipitated. The chromium may be precipitated from another portion of the filtrate as lead chromate.
—W. P. S.

Nickel; Cyanometric assay of ——. G. H. Stanley. J. S. Afr. Assoc. Anal. Chem., 1921, **4**, 10—12.

THE nickel solution is rendered slightly ammoniacal, a known amount of silver nitrate (allowance is made for this subsequently) and a small quantity of potassium iodide are added, and the mixture is titrated with standardised cyanide solution until the precipitate is dissolved completely. If iron is present, the nickel solution is treated with an excess of the cyanide solution, the required amount of ammonia is added rapidly, the mixture filtered, and the excess of cyanide titrated in the filtrate, the nickel being taken by difference. Copper must be removed previously, zinc is eliminated by adding sodium carbonate instead of ammonia to the solution already treated with cyanide, whilst the interference of manganese can be prevented by using ammonium carbonate in place of ammonia. Stannic compounds do not interefere.—W. P. S.

Cobalt; New method for the detection and determination of ——. S. A. Braley and F. B. Hobart. J. Amer. Chem. Soc., 1921, **43**, 482—484.

SOLUTIONS containing cobalt give, with a solution of dimethylglyoxime containing ammonia or sodium acetate, a brown coloration which is characteristic for cobalt inasmuch as, unlike the coloration given by other metals, it is not discharged by mineral acids. In absence of copper and iron it provides a sensitive qualitative test for cobalt. The colour can also be made to serve for a colorimetric estimation of cobalt in presence of nickel. The solution, prepared as for the determination of nickel, is slightly acidified, treated with sodium acetate, heated to boiling, and then the dimethylglyoxime added in slight excess. The nickel precipitate is filtered off, the solution cooled slowly, and when cold compared colorimetrically with standards.
—E. H. R.

Mercury and copper; Electrolytic separation of ——. W. Böttger. Z. angew. Chem., 1921, **34**, 120—122.

IN presence of chlorine ions the separation of mercury from copper is most effectively achieved by first removing both metals from the solution at a sufficiently high voltage, *e.g.*, 2·2—2·4 volts. They are then dissolved in dilute nitric acid, and the solution, after neutralisation and addition of acid and alcohol, is electrolysed at 1·4 volts. When potassium cyanide is added to a mercury-copper solution containing chlorine ions, the addition of a few c.c. of concentrated ammonia is advantageous in preventing decomposition of the cyanide. Separation of copper from such a solution takes place at normal temperature with a voltage of 3·2 volts; without ammonia the necessary voltage is 3·8—4·5 volts. At 65° C., an appreciably lower voltage, *e.g.*, 2 volts, may be used. (*Cf.* J.C.S., May.)—W. J. W.

Uranium, vanadium, and chromium; Qualitative separation and detection of —— when present together. P. E. Browning. J. Amer. Chem. Soc., 1921, **43**, 114—115.

A SOLUTION containing chromic and vanadic acids and a uranium salt is made faintly alkaline with ammonia and then faintly acid with acetic acid and treated with ammonium phosphate. Uranium phosphate is precipitated, filtered off, and washed. The identity of the uranium phosphate is confirmed by the addition to the precipitate of a drop of potassium ferrocyanide, when a red-brown stain is produced. The filtrate is treated with excess of sulphur dioxide to reduce the chromic and vanadic acids; the excess of sulphur dioxide is boiled off, an excess of bromine added, and the excess removed by boiling; this oxidises the vanadium to vanadic acid, but does not affect the chromium. Ammonia is added whereby the chromium separates as a green precipitate of phosphate and hydroxide. The filtrate from the chromium is made alkaline and saturated with hydrogen sulphide, which gives the pink or violet oxysulphide of vanadium.—J. F. S.

Gallium ferrocyanide; Use of —— in analysis. L. E. Porter and P. E. Browning. J. Amer. Chem. Soc., 1921, **43**, 111—114.

GALLIUM ferrocyanide passes through asbestos or filter paper in a Gooch crucible or filter paper in a funnel when suction is applied, but it can be filtered satisfactorily by using a pad made of shredded filter paper placed on a double filter paper and applying gentle suction. The precipitate after washing is ignited and weighed as the mixed oxides of gallium and iron. Gallium may be recovered from the ferrocyanide by solution in sodium hydroxide and precipitation of gallium hydroxide with carbon dioxide. An alternative method consists in treating the alkaline solution of gallium ferrocyanide with hydrogen peroxide to oxidise the sodium ferrocyanide to ferricyanide and then boiling with ammonium chloride, when pure gallium hydroxide is precipitated. When zinc is present neither method is available. In this case the metals are precipitated together as ferrocyanides which are dissolved in sodium hydroxide and the hydroxides precipitated by carbon dioxide. These are dissolved in hydrochloric acid and the gallium precipitated by boiling with ammonium bisulphite. Alternatively the alkaline solution of ferrocyanides is treated with hydrogen sulphide and the zinc precipitated, the gallium then being obtained by either of the methods described above.—J. F. S.

Nitric nitrogen; Comparative results with Scales' method and Devarda's alloy for reducing ——. A. P. Harrison. J. Biol. Chem., 1921, **46**, 53—56.

SCALES' zinc-copper couple gives as accurate results as Devarda's alloy, and has the advantage of not requiring to be weighed. 200 c.c. of solution with 0·1 mg. N per c.c. is poured into a flask containing about 80 g. of freshly prepared zinc-copper couple; about 5 g. of sodium chloride and 1 g. of magnesium oxide are added, and 150 c.c. is distilled into a flask containing 50 c.c. of 4% boric acid. Bromophenol blue is used as indicator in the titration.
—G. B.

Arsenate and arsenite; Separation and detection of ——. G. W. Sears. J. Amer. Chem. Soc., 1921, **43**, 466—470.

DETERMINATIONS of the solubility of silver arsenate and silver arsenite respectively in sodium hydroxide solution show that, whereas the former is readily dissolved in the cold by 0·5 to 1·5N sodium hydroxide, the latter is practically insoluble. The arsenate dissolves according to the equation

$$2Ag_3AsO_4+2NaOH+H_2O=2NaH_2AsO_4+3Ag_2O.$$

Higher concentrations of sodium hydroxide react slowly with silver arsenite with formation of arsenate and metallic silver. To separate arsenate and arsenite, their nitric acid solution containing excess of silver nitrate is neutralised with sodium hydroxide until the silver oxide precipitate just fails to re-dissolve. The washed precipitate is then shaken with about 25 c.c. of a solution containing about 3 c.c. of 6N sodium hydroxide solution. This is sufficient to dissolve at least 0·45 g. of silver arsenate. The arsenate and arsenite can be detected in the filtrate and residue respectively by usual methods.—E. H. R.

Air; Determination of nitrous fumes in —— with special reference to fuse-igniters. J. Moir. J. S. Afr. Assoc. Anal. Chem., 1921, **4**, 3—7.

A METHOD, similar to that of Ilosvay, but applicable to both small and large amounts of nitrite or nitrous acid, is described. The liquid under examination is treated with 1—10 c.c. of p-nitraniline solution (p-nitraniline, 1·5 g., concentrated hydrochloric acid, 10, water to 500 c.c.) and heated at 50° C.; 1—10 c.c. of α-naphthol solution (α-naphthol, 2, sodium hydroxide, 1·1, sodium acetate, 10 g., water to 500 c.c.) is then added and, after 1 hr., the orange-red precipitate is collected and weighed; 92 g. of NO_2, or 69 g. of $NaNO_2$, yields 293 g. of precipitate. The latter dissolves in sodium hydroxide solution with an intense blue-violet colour, and very small quantities may be determined colorimetrically. To determine NO_2 apart from nitrite in the fumes from fuse igniters, a definite volume of the gases may be left in contact with neutral hydrogen peroxide solution for 24 hrs., and the solution then titrated, using methyl orange as indicator; 1 c.c. of $N/10$ alkali is equivalent to 0·0060 g. NO_2. Alternatively, neutral potassium iodide solution may be used in place of the hydrogen peroxide and the liberated iodine titrated with thiosulphate solution; each c.c. of $N/10$ thiosulphate solution=0·0051 g. NO_2.—W. P. S.

Iodoform reaction; Sensitive modification of the ——. N. Schoorl. Pharm. Weekblad, 1921, **58**, 209—210.

AMMONIUM persulphate is used with potassium iodide in alkaline solution. The reaction will detect 1 pt. of acetone in 100,000. (*Cf.* J.C.S., April.)
—S. I. L.

Miscible liquids; Separation of —— by distillation. S. F. Dufton. Phil. Mag., 1921, **41**, 633—646.

THE still-head described previously by the author (J., 1919, 45 T) gives a complete separation of simple binary mixtures and renders possible the examination of the rationale of separation by distillation. The physical processes occurring in the still-head are discussed mathematically and amplified by experimental data. Comparison of continuous and discontinuous distillation shows that the former is much more economical; further, a column can be employed at its maximum efficiency throughout, whilst the length must be variable if the highest efficiency in discontinuous distillation is to be obtained.—W. P. S.

PATENTS.

Gas analysing apparatus. Aktiebolaget Ingeniörsfirma F. Egnell. E.P. 106,265, 29.9.16. Conv., 8.5.16.

IN gas analysing apparatus provided with an oxidation chamber and a vessel for absorption of carbon dioxide, a cock is arranged between the gas generator and the analysing apparatus and is of such construction that the gas to be analysed can be passed from the generator through the cock to the absorption vessel, thence, through the cock to the oxidation chamber and finally through the cock to the analysing apparatus, or directly through the cock to the latter. If desired, the gas may be led directly from the absorption vessel to the analysing apparatus, and the gas generator may be shut off from the rest of the apparatus. The cock is provided with a device for closing and breaking the electric circuit for heating the oxidation chamber.
—J. S. G. T.

Gases and vapours capable of being absorbed; Continuous determination of ——. Badische Anilin- und Soda-Fabrik. G.P. 329,386, 27.4.18.

The gaseous mixture is simultaneously delivered through two parallel circuits, each provided with a pair of throttle valves. In the one circuit, absorption of the gas or vapour concerned is effected, and the difference of pressure in the two circuits arising therefrom at constant temperature enables the amount of the absorbed constituent to be ascertained.—J. S. G. T.

Thermo-element for the measurement of high temperatures. F. Hesse. G.P. 330,726, 5.3.18.

The thermo-junction is constituted of tantalum and molybdenum and is fused into a sheath filled with basic refractory material to prevent oxidation. —J. S. G. T.

Heating-value indicator. U.S.P. 1,370,945. *See* II a.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Acheson. Deflocculating solid substances. 11,199. Apr. 18. (U.S., 1.5.20.)

Akt.-Ges. f. Stickstoffdünger. Treatment of feed-water for steam generators etc. 10,608. Apr. 11. (Ger., 12.4.20.)

Beldimano, Robertson, and Stanley. Evaporating or heating liquids. 10,953. Apr. 14.

Brown. Carbon bleaching or filtering material, and method of making same. 11,580. Apr. 21. (U.S., 12.8.20.)

Chaudière. Furnaces, gas-producers, etc. 11,321. Apr. 19. (Belg., 20.4.20.)

Johnston. Machines for centrifugally separating solids from liquids. 10,901. Apr. 14.

Leubli. Grinding-mills. 10,963. Apr. 14.

Marks (Shell Co.). Re-run still. 11,438. Apr. 20.

Mercer. Pulverising or disintegrating machines. 10,634. Apr. 12.

Powdered Fuel Plant Co., Ltd. Means for separating suspended solid from a gaseous medium. 11,014. Apr. 15. (Fr., 12.8.20.)

Reid. Furnaces. 10,704. Apr. 12.

Rigby. Drying-cylinders. 11,278–9. Apr. 19.

Complete Specifications Accepted.

15,265 (1918). Gal. Furnaces. (122,395.) Apr. 20.

19,287 (1919). Harris. Drying process and apparatus. (161,598.) Apr. 27.

19,639 (1919). Junquera. Manufacture of concentrated solutions. (144,240.) Apr. 27.

29,288 (1919). Coleman. Mixing and agitating machines. (161,617.) Apr. 27.

169 (1920). Paget. Grinding, refining, or reducing apparatus. (161,257.) Apr. 20.

325 (1920). Still. Filters. (161,639.) Apr. 27.

1176 (1920). Hirsch. Apparatus for generating gas by the action of liquids on solid reagents. (161,681.) Apr. 27.

3707 (1920). Barbet et Fils et Cie. Condensing arrangements of rectifying apparatus. (138,869.) Apr. 20.

5224 (1920). Kennedy. Gyratory crushing apparatus. (139,216.) Apr. 27.

5714 (1920). Dorr Co. Rotating screen filtering apparatus. (139,493.) Apr. 20.

8943 (1920). Johnson (Fischlein). Centrifugal apparatus for straining liquids. (161,822.) Apr. 27.

20,141 (1920). Danhardt. Asbestos cloth, especially for dry separation of solid matter from blast-furnace gases etc. (153,558.) Apr. 20.

20,289 (1920). Rudisill. Pulveriser. (148,369.) Apr. 20.

24,280 (1920). Hardinge. Grinding and disintegrating mills. (150,997.) Apr. 27.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Accioly. Manufacture of an alcoholic liquid (synthetic) gas for use as combustible. 11,419. Apr. 20.

Bowler. Distilling crude petroleum. 11,623. Apr. 22.

Burnet. Vertical retorts for destructive distillation. 10,834. Apr. 13.

Burton. Gas-retort mouthpieces. 11,134. Apr. 16.

Carratt. Gas-producers. 11,393. Apr. 20.

Chaudière. 11,321. *See* I.

Clapp, and Ferolite, Ltd. Gas-producers, electric furnaces, crucible furnaces, etc. 11,065. Apr. 15.

Davidson, and Low Temperature Carbonisation, Ltd. Retorts. 11,222. Apr. 18.

Dehn (McComb). Converting heavy liquid hydrocarbons or liquid hydrocarbons of higher boiling point into lighter hydrocarbons or hydrocarbons of lower boiling point. 11,116. Apr. 16.

Frentrup, Kiederich, and Meyer zu Eissen. Increasing the consistency of hydrocarbon oils etc. 10,692. Apr. 12.

Glawe. Mixing briquette-forming materials with fluid binding agent. 10,919. Apr. 14.

Keith, Whatmough, and Keith and Blackman Co., Ltd. Liquid fuel, and process for production thereof. 11,444. Apr. 20.

Marks (Shell Co.). 11,438. *See* I.

Powdered Fuel Plant Co., Ltd. Apparatus for pulverising coal etc. 11,012–3. Apr. 15. (Fr., 17 and 31.8.20.)

Trent Process Corp. Process of separating oils. 10,828. Apr. 13. (U.S., 11.8.20.)

Trent Process Corp. Manufacture of combustible gas. 10,829. Apr. 13. (U.S., 31.8.20.)

Trent Process Corp. Distillation of oils. 10,831. Apr. 13. (U.S., 4.11.20.)

Welford. Treatment of hydrocarbons. 11,074. Apr. 16.

Wood. Gas-retorts. 11,041. Apr. 15. (Australia, 15.4.20.)

Complete Specifications Accepted.

24,047 (1919). Rütgerswerke A.-G. Process of making a substitute for petroleum jelly. (134,528.) Apr. 20.

24,852 (1919). U.S. Industrial Alcohol Co. Liquid fuel. (133,709.) Apr. 27.

25,104 (1919). Low Temperature Carbonisation, Ltd., Davidson, and Armstrong. Retorts for distilling carbonaceous substances. (161,608.) Apr. 27.

32,280 (1919). Rütgerswerke A.-G. Production of soot carbon, retort graphite, and other carbon products from natural gas. (137,065.) Apr. 20.

70 (1920). Paris. Cleaning and refining petroleum and analogous distillates. (161,253.) Apr. 20.

8797 (1920). U.S. Industrial Alcohol Co. Liquid fuels. (140,797.) Apr. 20.

17,612 (1920). Nasspress Ges. Process of drying raw peat. (146,214.) Apr. 20.

18,266 (1920). Bergius and Kalnin. Separate recovery of constituents of the distillation of gas from fuel. (146,332.) Apr. 27.
19,518 (1920). Still. Purifying coal gas by means of ammonia. (147,583.) Apr. 27.
20,141 (1920). Danhardt. *See* I.

III.—TAR AND TAR PRODUCTS.

Applications.

Commin and Hughes. Treatment of pitch. 11,060. Apr. 15.
Imray (Soc. Chem. Ind. in Basle). Manufacture of α-aminoanthraquinone. 11,459. Apr. 20.
Koppers Co. Purification of phenol-contaminated liquors. 10,603. Apr. 11. (U.S., 30.4.20.)

Complete Specifications Accepted.

4595 (1920). Koppers Co. Purification of liquors containing phenoloid bodies. (139,168.) Apr. 20.
14,276 (1920). South Metropolitan Gas Co., and Stanier. Manufacture of certain naphthylamine-sulphonic acids. (161,859.) Apr. 27.
19,128 (1920). Meister, Lucius, u. Brüning. Manufacture of pyridine bases. (147,101.) Apr. 20.

IV.—COLOURING MATTERS AND DYES.

Complete Specification Accepted.

20,256 (1920). Cassella und Co. Manufacture of a new colour of the anthraquinone series. (148,339.) Apr. 20.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bloxam (Technochemia A.-G.). Manufacture of textile products from animal fibres. 11,461. Apr. 20.
Courtaulds, Ltd., Callimachi, and Hegan. Manufacture of threads, filaments, etc. of cellulose. 11,766,*11,768–9.
Courtaulds, Ltd., and Wilson. Production of coloured threads, filaments, etc. 11,770. Apr. 23.
Dreyfus. Manufacture of cellulose derivatives. 11,293. Apr. 19.
Krantz. Method of drying textile materials. 11,169. Apr. 18.
Plauson's (Parent Co.), Ltd. (Plauson). Manufacture and treatment of viscose. 10,615. Apr. 12.

Complete Specifications Accepted.

22,680 (1919). Pickup and Wilson. Treating fibres. (161,600.) Apr. 27.
27,596 (1919). Pritchard. Degumming and washing fibres. (161,219.) Apr. 20.
30,954 (1919). Maupai. Process of treating silks. (161,625.) Apr. 27.
694 (1920). Power Gas Corp., and others. *See* XVIII.
6520 and 6643 (1920). B. G. Textilwerke Ges. Balloon envelope materials. (139,795 and 139,807.) Apr. 27.
17,721 (1920). Soc. Suisse de Ferments. Degumming textile materials. (145,583.) Apr. 27.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Courtaulds, Ltd., and Wilson. 11,770. *See* V.
Dicker (Bever). Impregnating and dyeing porous materials. 10,613. Apr. 11.
Farrell. Dye-jigs or becks. 10,627. Apr. 12.
Henshilwood and Thornber. Machines for bleaching, dyeing, etc. 11,272. Apr. 19.

Complete Specifications Accepted.

13,161 (1920). Bayer u. Co. Process for dyeing with acid sulphoamino dyestuffs, and the manufacture of new lakes. (143,242.) Apr. 20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Allen and Hanburys, Ltd., and Lizius. 11,659. *See* XXIII.
Chem. Fabr. Griesheim-Elektron, Pistor, Reitz, and Schultze. Manufacture of stable compounds containing active oxygen and calcium. 10,771. Apr. 13.
Constant and Raisin. Production of boron. 11,645. Apr. 22. (Fr., 22.4.20.)
Deuts. Gold- u. Silber-Scheideanstalt. Production of sodium cyanide. 11,717. Apr. 22. (Ger., 10.6.20.)
Feldenheimer and Plowman. Process for grading alkaline-earth carbonates. 11,358. Apr. 19.
Mirat and Pipereaut. Manufacture of sulphuric acid. 10,792. Apr. 13. (Belg., 6.5.20.)
Pease. Manufacture of compounds of ammonia etc. 11,039. Apr. 15.
Riedel A.-G. 11,068. *See* XX.

Complete Specifications Accepted.

10,401 (1918). Deuts. Gold- u. Silber-Scheideanstalt. Manufacture of alkali percarbonates. (117,085.) Apr. 27.
24,875 (1919). Spence and Sons, Spence, and Llewellyn. Manufacture of aluminous compounds. (161,606.) Apr. 27.
30,611 (1919). Patrick. Silica gels and process of making same. (136,543.) Apr. 20.
32,756 (1919). Douglas. Manufacture of ammonia. (161,244.) Apr. 20.
353 (1920). Kelly. Manufacture of acid sodium pyrophosphate. (161,273.) Apr. 20.
822 (1920). Mackay. Obtaining strontium and barium sulphates from their native sulphates. (161,655.) Apr. 27.
823 (1920). Mackay. Obtaining copper sulphate direct from metallic copper. (161,656.) Apr. 27.
1231 (1920). Wildman. Extraction of alumina and its salts from clay. (161,310.) Apr. 20.
10,004 (1920). Clayton. Apparatus for manufacture of oxygen compounds of sulphur. (161,439.) Apr. 20.
17,437 (1920). Röhm. Production of a solid non-hygroscopic iron salt. (146,214.) Apr. 20.

VIII.—GLASS; CERAMICS.

Applications.

Clark, Taylor, and Universal Transfer Co. Process for pottery printing. 10,741. Apr. 13.
Rigby. Treatment of china clay etc. 11,093. Apr. 16.
Wallis. Composition for manufacture of crockery-ware. 11,139. Apr. 18.

IX.—BUILDING MATERIALS.

Applications.

Brant. Building etc. materials. 10,781. Apr. 13.
Lyno. Cement brick. 11,574. Apr. 21. (Denmark, 27.4.20.)
Miller, Miller, and Williams. Damp-insulating material for buildings etc. 11,249. Apr. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

13,164 (1920). Wennerstrom. Manufacture of cement. (143,243.) Apr. 27.
16,297 (1920). Schiff. Manufacture of dental cements. (161,868.) Apr. 27.
17,312 (1920). Larsen. Manufacture of porous cement or mortar products. (146,172.) Apr. 27.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Beielstein, and Chem. Fabr. Griesheim-Elektron. Recovery of light metals from scrap. 11,066. Apr. 15.
British Thomson-Houston Co. (General Electric Co.). Electro-metallurgy. 11,049. Apr. 15.
Chandler, and South Metropolitan Gas Co. Gas-fired metallurgical furnaces. 11,699. Apr. 22.
Clapp and others. 11,065. *See* II.
Coles. Manufacture of bronze powders. 11,520. Apr. 21.
Continuous Reaction Co., Merson, and Skelley. Manufacture of ferrotungsten and ferromolybdenum. 11,786. Apr. 23.
Continuous Reaction Co., Skelley, and Smith. Manufacture of ferrous alloys. 11,787. Apr. 23.
Danforth. Open-hearth furnaces. 11,437. Apr. 20.
Hervey and Taylor. Treatment of iron. 10,707. Apr. 12.
Rogers (Calorizing Corp. of America). Calorizing furnace and process. 11,310. Apr. 19.
Rogers (Calorizing Corp. of America). Metallic alloys. 11,311. Apr. 19.
Sweeney. Manufacture of composite metallic sheets. 10,846. Apr. 13.
Trent Process Corp. Process of reducing ores. 10,830. Apr. 13. (U.S. 4.10.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

24,480 (1919). Morgan Crucible Co., and Speirs. Electrically heated melting and other furnaces. (161,603.) Apr. 27.
821 (1920). Mackay. Obtaining iron and tin from tin scrap. (161,654.) Apr. 27.
3692 (1920). Vigeon and McConway. Pre-leaching apparatus for treating calcined ore and the like. (161,375.) Apr. 27.
4146 (1920). Crosthwaite Eng. and Furnace Co., and Crosthwaite. Furnaces for heating crucibles employed for melting or heating metals etc. (161,386.) Apr. 20.
20,141 (1920). Danhardt. *See* I.
23,238 (1920). Tugwood (Dwight and Lloyd Metallurgical Co.). Ore-sintering mechanisms. (161,491.) Apr. 20.
658 (1921). Agostini. Solder for aluminium and other metals. (156,665.) Apr. 20.

XI.—ELECTRO-CHEMISTRY.

APPLICATION.

Clapp and others. 11,065. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

24,480 (1919). Morgan Crucible Co., and Speirs. *See* X.
25,052 (1919). Trembour. Electric furnaces. (133,954.) Apr. 27.
27,150 (1919). Boorne and Darge. Covering metal cores in the manufacture of electrodes. (161,212.) Apr. 20.
66 (1920). Bultemann. Manufacture of an electric insulating material. (137,326.) Apr. 20.
29,780 (1920). Smalley. Electric furnaces. (152,686.) Apr. 27.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Eppenberger. Rendering fat-containing granular products impalpable. 10,940. Apr. 14. (Switz., 1.3.21.)
Fenton. Treating oil-bearing solids. 10,710. Apr. 12.
Kobayashi. Manufacture of hydrocarbons from fatty oils. 11,712. Apr. 22. (Japan, 13.10.20.)
Plauson's (Parent Co.), Ltd. (Plauson). Compositions of oils etc. 10,616. Apr. 12.
Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of viscous oily compositions. 10,852. Apr. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

30,543 (1919). Heyerdahl. Extraction and refining of oil. (137,514.) Apr. 20.
8354 (1920). Quick. Refining and decolorising animal and vegetable oils. (161,813.) Apr. 27.
18,752 (1920). Elektro-Osmose A.-G. Purification of glycerin. (146,865.) Apr. 27.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATION.

Dargan. Luminous ink. 11,163. Apr. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

17,490 (1919). Ivinson and Roberts. Anti-corrosive paint or composition. (161,201.) Apr. 20.
24,916–7 (1919). Melamid. Production of resin-like bodies. (133,712–3.) Apr. 27.
469 (1920). Baker. Process of making pigments. (161,280.) Apr. 20.
13,161 (1920.) Bayer u. Co. *See* VI.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Catalpo, Ltd., and Schidrowitz. Manufacture of caoutchouc and caoutchouc-like products. 11,055. Apr. 15.
Moler. Manufacture of regenerated rubber. 11,053. Apr. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

748 (1920). Gare. Reforming or vulcanising rubber, ebonite, vulcanite, etc. (161,648.) Apr. 27.
799 (1920). Farrel Foundry and Machine Co. Mixing or masticating rubber etc. (137,820.) Apr. 20.
4264 (1920). Helbronner. Manufacture of india-rubber products. (142,083.) Apr. 27.
6670 (1920). Bruni. Vulcanisation of rubber. (140,387.) Apr. 27.
18,916 and 18,920 (1920). Wade (Goodyear Tire and Rubber Co.). Manufacture of rubber products. (161,482–3.) Apr. 20.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Richter. Removal of hairs from hides etc. 10,775. Apr. 13.
Soc. Pichard Frères. Process for unhairing hides. 11,638. Apr. 22. (Fr., 12.5.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

27,772 (1919). Malcolm and Townsend. Manufacture of vegetable gelatin. (161,612.) Apr. 27.
2652 (1920). Boys. Apparatus for mixing or agitating lime in tannery pits. (161,362.) Apr. 20.

8681 (1920). Bray (Indian Wood Products Co.). Manufacture of catechin and catechu-tannic acid. (161,431.) Apr. 20.

XVI.—SOILS; FERTILISERS.

Complete Specification Accepted.

4803 (1920). Sams. Fertiliser and process of making same. (161,777.) Apr. 27.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Brown. Washing starch. 11,581. Apr. 21. (U.S., 12.8.20.)

Courtaulds, Ltd., Lloyd, and Stokes. Production of compounds or mixtures of starch and sulphuric acid. 11,767, 11,782. Apr. 23.

Tiemann. Purifying sugar juices by filtration and decantation. 11,561. Apr. 21. (Ger., 21.4.20.)

Complete Specifications Accepted.

1972 (1920). Barbet et Fils et Cie. *See* XIX.

11,691 (1920). Classen. Manufacture of sugar and furfurol from wood and other cellulosic substances. (142,480.) Apr. 27.

12,609 (1920). Terrisse and Levy. Obtaining glucose from wood. (143,212.) Apr. 20.

18,744 (1920). Wohl. Saccharification of cellulose-containing materials. (146,860.) Apr. 27.

22,019 (1920). Tavroges, Roche, and Martin. Manufacture of lactcse or milk sugar. (161,887.) Apr. 27.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specifications Accepted.

12,490 (1917). Fernbach. Production by fermentation of acetone and higher alcohols, particularly butyl alcohol. (109,969.) Apr. 20.

694 and 8114 (1920). Power Gas Corp., and Langwell. Fermentation of cellulose. (161,294.) Apr. 20.

16,395 (1920). Romer, and Deutsch-Koloniale Gerb- u. Farbstoff-Ges. Fermentation process. (161,870.) Apr. 27.

21,673 (1920). Stouffs. Preservation of by-products of brewing, distilling, etc., for use as animal foods. (161,885.) Apr. 27.

23,828 (1920). Warwick. Apparatus for fermentation of beer etc. (161,496.) Apr. 20.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Abbott, McNeill, Macredie, and Remus. Production of meat powder. 10,682. Apr. 12.

Akt.-Ges. f. Stickstoffdünger. 10,608. *See* I.

Chalas. Manufacture of a dry and soluble extract of roasted coffee. 11,046. Apr. 15. (Fr., 16.4.20.)

Complete Specifications Accepted.

32,239 (1919). Forget-Me-Not, Ltd., and Hutchinson. Manufacture of alimentary products containing water-soluble vitamines. (161,238.) Apr. 20.

643 (1920). Farmachidis. Food preparation. (161,291.) Apr. 20.

1135 (1920). White (Collis Products Co.). Desiccating buttermilk etc. (161,678.) Apr. 27.

1800 (1920). Collis Products Co. Apparatus for desiccating buttermilk, sour milk, etc. (138,092.) Apr. 27.

1972 (1920). Barbet et Fils et Cie. Manufacture of grape honeys and fruit syrups. (153,548.) Apr. 27.

2695 (1920). Linden. Apparatus for treating effluent and other liquids. (161,735.) Apr. 27.

3645 (1920). Clements. Producing materials suitable for purifying air. (138,649.) Apr. 27.

21,673 (1920). Stouffs. *See* XVIII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Alby United Carbide Factories, Ltd., and Dodd. Manufacture of salts of guanidine. 11,646. Apr. 22.

Büchler. Production of borodisalicylic acid. 11,553. Apr. 21.

Courtaulds, Ltd., and Delph. Manufacture of carbon bisulphide. 11,771. Apr. 23.

Riedel A.-G. Soluble mercury compounds. 11,068. Apr. 15. (Ger., 16.4.20.)

Complete Specifications Accepted.

2787 (1916). Weizmann and Legg. Manufacture of secondary butyl alcohol. (161,591.) Apr. 27.

12,490 (1917). Fernbach. *See* XVIII.

1140 (1920). Ellis (Soc. Chim. Usines du Rhône). Manufacture of oxyaldehydes and their derivatives. (161,679.) Apr. 27.

2196 (1920). Thomson. Detoxication of the tubercle bacillus and other germs for the preparation of vaccines. (161,341.) Apr. 20.

11,691 (1920). Classen. *See* XVII.

24,192 (1920). Elektro-Osmose A.-G. Process for making specific vaccines. (150,319.) Apr. 20.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Davies. Manufacture of photographic papers. 10,949—10,951. Apr. 14.

Marks (Daylight Film Corp.). Photographic reproduction. 10,586. Apr. 11.

Martinez. Colour sensitised supports for colour photography etc., and treatment thereof. 10,773. Apr. 13.

Warneuke. Colour photograhy. 11,294. Apr. 19.

Wolff. Colour photography and kinematography. 11,556. Apr. 21. (Ger., 14.8.20.)

XXIII.—ANALYSIS.

Applications.

Allen and Hanburys, Ltd., and Lizius. Titration and neutralisation of chemical compounds. 11,659. Apr. 22.

Svenska Aktiebolaget Mono. Gas-analysing apparatus. 11,359. Apr. 19. (Sweden, 23.4.20.)

I.—GENERAL; PLANT; MACHINERY.

Water; Heat conductivity of —— between 0° and 80° C. M. Jakob. Ann. Phys., 1920, [4], 63, 537—570. Chem. Zentr., 1921, 92, II., 689—690.

The heat conductivity of water in C.-G.-S. units (cals. per cm. per sec. per 1° C.), between 0° and 80° C., is given correct to 1% by the equation $\lambda=0.001325\ (1+0.002984t)$.—A. R. P.

Patents.

Liquids, pulpy masses, and the like; Process and apparatus for solidifying in fine powder ——. [Manufacture of soap powder.] Metallbank und Metallurgische Ges. A.-G. E.P. 145,048, 15.6.20. Conv., 16.4.18.

The liquid (*e.g.*, molten soap) is sprayed centrifugally and subjected to the action of a current of cold air which is continuously circulated through the spraying apparatus and a cooler.—B. M. V.

Reaction towers [; Filling for ——]. H. Schmidt. E.P. 147,213, 7.7.20. Conv., 11.4.19.

Metallic strip is perforated and corrugated with corrugations of equal pitch, the strips being laid together with the tops of the corrugations touching so that a honeycomb structure is formed.—B. M. V.

Vapours of volatile liquids; Process and apparatus for the recovery of —— from their mixtures with air. E. Barbet et Fils et Cie. E.P. 149,691, 3.8.20. Conv., 1.8.19.

Air escaping from a storage vessel containing a volatile liquid is passed through a washing column. The column contains a suitable solvent (*e.g.*, heavy tar oil for benzene) which is fed from a storage tank only when there is positive pressure in the storage vessel, *i.e.*, when air is escaping. The control of the solvent feed is effected by a float in a two-compartment tank, closed at the top, and partially filled with the solvent liquid; the two compartments communicate only below the level of the liquid. One compartment (preferably the larger) contains the float and valve for supplying the solvent liquid, which flows from the other compartment to the washing column through a hand-adjusted outlet situated just above the level reached by the liquid when the float valve closes. The arrangement is made very sensitive by putting the air space above the float in communication with the air space in the storage vessel. A separate liquid seal device is provided through which air can be drawn into the storage vessel if the pressure therein falls below a predetermined limit.—B. M. V.

Drying apparatus. L. Eberts. E.P. 160,717, 19.8.20.

The material to be dried is admitted into a casing within which rotates a drum heated by a fluid which is admitted and exhausted through the hollow trunnions of the drum. Stirrers attached to the drum gradually propel the material to an outlet, and additonal heating surface is provided by means of tubes projecting radially from the drum, either bent to a U-shape and having both ends communicating with the drum or having their outer ends connected with longitudinal tubes which are in turn connected with spiral tubes leading to the outlet. The radial tubes may be wedge-shaped in cross-section.—B. M. V.

Drying apparatus. T. Izumi. U.S.P. 1,372,352, 22.3.21. Appl., 10.6.20.

A vertical cylindrical drying chamber is fitted with shelves revolving around a central cylindrical heat radiator, and means are provided for drawing air from the bottom of the chamber and causing it to escape through a passage around the chamber, air pipes within the passage serving to supply fresh air to the top of the chamber. The lowest part of the chamber communicates with a fluid pit provided with a lid.—H. H.

Drying apparatus. Z. Yamamoto. U.S.P. 1,372,585, 22.3.21. Appl., 28.11.19.

A drying apparatus comprises a casing in which is mounted a movable frame carrying a zig-zag shoot having an inlet at its top and an outlet at its bottom. Means are provided for heating the interior of the casing, and the shoot has openings to permit the heated air to enter.—H. H.

Dryer. W. F. Schaller, Assr. to E. and I. H. Schaller. U.S.P. 1,373,767, 5.4.21. Appl., 11.9.18.

Three walls of the drying chamber are surrounded by a hot-air chamber below which is a fire chamber with flues for the products of combustion, and there are also provided flues for supplying fresh air to the drying chamber and for heating it, a flue extending downwards from one end of the drying chamber and formed with an opening at its lower end for mixing the incoming air, and a flue at the opposite end of the drying chamber for escape of the heated air.—H. H.

Cooling towers. L. R. Morshead. E.P. 160,990, 17.1.20.

Jets of water are arranged at the bottom of the tower, pointing upwards, in order to induce a more powerful current of air, especially in those parts where by natural draught there would be little or no current and to prevent water being blown out by cross winds. Falling water which would fall directly on the jets may be deflected by louvres.—B. M. V.

Heating and cooling liquids; Apparatus for ——. C. W. Desobry. U.S.P. 1,373,953, 5.4.21. Appl., 17.3.19.

The liquid to be cooled flows downwards in a zig-zag path over vertical inner walls of chambers which are divided into two similar sections, hinged at one side so that they can be opened and closed. Heating or cooling means may be installed between the inner and outer walls of the chambers.—B. M. V.

Electrical precipitation [of vaporised substances from gases]. A. F. Nesbit. U.S.P. 1,371,995, 15.3.21. Appl., 10.12.20.

The gases are passed through an apparatus containing several pairs of electrodes, each pair consisting of a discharge electrode and a tubular collecting electrode, producing between them an ionisation field which is cooled by a refrigerating jacket surrounding the collecting electrode and in which vaporised substances are deposited from the gases. Traps are provided at intervals along the collecting electrodes.—J. H. L.

Cleaning gases; [Electrical] method of and apparatus for ——. F. R. McGee and A. F. Nesbit. U.S.P. 1,372,710, 29.3.21. Appl., 13.3.18.

The gas is passed through a hollow electrode in which a corona discharge is maintained. A whirling motion is imparted to the column of gas, whereby impurities are impelled centrifugally to the periphery. The central core of clean gas and the peripheral layer of gas laden with impurities are passed into separate chambers.—J. S. G. T.

Dust separator; Centrifugal ——. H. Milliken, Assr. to J. B. Taylor. U.S.P. 1,372,714, 29.3.21. Appl., 20.9.19.

A centrifugal dust separator for gases comprises a tubular envelope provided with one or more helical slits affording a free passage radially and extending around the periphery of the envelope. A structure within the envelope affords a continuous helical passage in the same general direction as the helical slit or slits.—J. S. G. T.

Gases; Process and apparatus for removing vaporised, liquid and solid substances from —— *by washing.* W. Freytag. G.P. 331,321, 20.8.18.

The gas is passed through a rotary wheel-shaped filtering apparatus containing a porous material which is automatically moistened, but not overcharged, with crude oil, tar, heavy oil or the like. When the filtering material is no longer effective it is automatically replaced by fresh. Materials such as porous lignite or peat are preferably employed so that after use they can be distilled in order to recover the oily washing liquid.—J. H. L.

Feed-water heater, evaporator, and the like. H. C. Davis, Assr. to American Marine Equipment Corp. U.S.P. 1,372,010, 22.3.21. Appl., 19.9.18.

A horizontal shell has an inlet and outlet for steam, inlet and outlet connexions for water, and a nest of straight horizontal tubes in communication with the water connexions, each tube being provided with a longitudinal indentation extending spirally around it.—H. H.

Filter apparatus. O. Congleton; J. T. Lewis, exor. U.S.P. 1,372,119, 22.3.21. Appl., 4.4.18.

Filtering material is disposed between an upper chamber and a tapering lower chamber of a filter tank. The lower chamber has a valved outlet, and a connexion is provided from a supply tank to the lower chamber, such connexion having an upwardly inclined portion entering the tapering wall of the lower chamber. A series of such filter tanks may be provided, the valved outlets from the lower chambers leading to a common pipe, and each upper chamber having a pipe connexion to the lower chamber of the succeeding tank. The upper chamber of the final tank is provided with an outlet pipe, and the supply tank is connected with the upper chambers of the various filter tanks.—H. H.

Filtration process. D. P. Hynes, Assr. to Roseberry Surprise Mining Co., Ltd. U.S.P. 1,373,887, 5.4.21. Appl., 26.1.20.

A basic compound of zinc is added to a pulp containing solid and colloidal substances and substantially free from acid, whereby the colloidal substances are changed to a form which does not inhibit filtration.—A. de W.

Distilling column. G. W. Crupe, Assr. to Semet-Solvay Co. U.S.P. 1,372,649, 22.3.21. Appl., 23.10.20.

In a distilling column having a series of superimposed pans with an external overflow passage from pan to pan, there is a vent pipe connexion from the upper part of each such passage, and the vent pipe has a discharge orifice within the column, above the opening from the pan to the passage. —H. H.

Still. C. D. Crane. U.S.P. 1,372,865, 29.3.21. Appl., 18.7.17.

In a still of the type in which the main shell is divided into a lower generator compartment and an upper compartment for condensing medium, the division wall forming the condensing surface, a settling chamber is arranged external to the main shell. A fluid supply conduit leads from the upper compartment of the still to the settling chamber, and an overflow connexion leads from the settling chamber to the lower compartment of the still. —H. H.

Distilling and purifying apparatus for volatile liquids. H. A. Hills. U.S.P. 1,372,880, 29.3.21. Appl., 18.8.16.

A still having a sloping bottom, a vapour outlet at the top, and a liquid inlet is provided with a nozzle having its discharge opening directed against the bottom. A sleeve forms an annular chamber around the nozzle, and an opening is provided at the rear of the chamber through which fluid is supplied by suction simultaneously with the exhaust from the nozzle.—H. H.

Crucible furnace. J. H. L. De Bats, Assr. to Lava Crucible Co. U.S.P. 1,372,676, 29.3.21. Appl., 3.3.17. Renewed 5.8.20.

A crucible furnace comprises a main chamber with a bottom, adapted to be lowered and lifted, on which is erected a crucible-receiving chamber with non-perforated heat-conducting walls of refractory material, spaced from the walls of the main chamber to provide a fire space. The bottom of the space surrounding the crucible-receiving chamber is formed as a grate.—H. H.

Catalytic material and process of making the same. A. A. Backhaus, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,372,736, 29.3.21. Appl., 19.12.18.

A catalytic material is made by applying syrupy phosphoric acid to coke, using a diminished pressure before and during the application, then restoring the pressure and reducing the acid content to about 15%.—H. H.

Centrifugal separation; Process for ——. E. W. Beach. U.S.P. 1,373,219, 29.3.21. Appl., 31.1.21.

For separating a heavier solid from a lighter fluid constituent of a mixture, a centrifugal machine is used having a discharge passage near its outer wall and another discharge passage relatively close to its centre of rotation, and there is introduced into the machine a sealing and carrying fluid of a specific gravity intermediate between the specific gravities of the constituents to be separated. Sufficient of the sealing liquid is used to form a layer against the outer wall to close completely the outer discharge passage. This layer prevents the lighter constituent from passing through that passage while allowing the heavier constituent to be removed with the sealing material.—H. H.

Centrifugally separating substances; Method and mechanism for ——. L. D. Jones, Assr. to The Sharples Specialty Co. U.S.P. 1,373,743, 5.4.21. Appl., 4.9.20.

Three substances of differing densities are separated by subjecting them to centrifugal force and controlling the distance of the contact surfaces of the stratified constituents from the centre of revolution so that either contact surface of the intermediate layer may vary substantially without substantially varying its other contact surface. H. H.

Emulsions; Method of resolving ——. P. T. Sharples. U.S.P. 1,373,773, 5.4.21. Appl., 21.10.18.

A three-phase emulsion is centrifuged to effect separation with the separate discharge of the lightest phase. The discharge is retarded so as to hold a relatively large volume of the lightest phase in the centrifuge, and this is subjected to the highest centrifugal force which is practicable without any substantial discharge of the lightest phase with the heavier phases.—H. H.

Centrifugal separation; Method of and machine for ——. W. H. Peck. U.S.P. 1,374,098, 5.4.21. Appl., 14.11.19.

THE mixture is stratified centrifugally, the heavier matter is discharged through ports, and fluid under pressure is caused to act through the ports against the outflow of the heavier particles and then to discharge with the lighter particles through other ports.—H. H.

Extracting valuable components [soluble salts] from raw materials; Process of ——. J. W. Hornsey. U.S.P. 1,373,731, 5.4.21. Appl., 29.6.16.

RAW material containing the soluble salt together with other ingredients is caused to move in contact with and in a counter direction to a mother liquor saturated with other ingredients, within the range of working temperatures employed. The liquor is agitated, solid and liquid are separated, and the liquid is removed from a quiet zone remote from the agitated zone.—J. S. G. T.

Thickener (sewage type). Automatic separator. C. Allen. U.S.P. (A) 1,374,134, and (B) 1,374,135, 5.4.21. Appl., 11.3 and 8.6.20.

A SETTLING vessel is provided with an overflow rim and with a discharge pipe for settled material which extends nearly to the bottom. In (A) the discharge pipe is brought out through the side of the vessel near the top (siphon action) and the rate of discharge controlled by a valve actuated by a float at about the level of the settled material. In (B) the fixed discharge pipe extends vertically upwards above the vessel; the vessel itself is mounted on springs and provided with a valve which closes the discharge pipe when the vessel is light but opens when the vessel reaches a pre-determined weight, the discharge being effected by a fluid pressure pipe opening into the discharge pipe, *e.g.*, by an air lift.—B. M. V.

Furnace. A. Smallwood. U.S.P. 1,373,152, 29.3.21. Appl., 17.7.20.

SEE E.P. 153,042 of 1919; J., 1920, 809 A.

Charging apparatus for furnaces, kilns, and the like. C. Candlot. E.P. 137,297, 29.12.19. Conv., 10.7.17.

Pulverised coal and other material; Feeding —— to furnaces [by means of air under pressure]. P. E. van Saun. E.P. 160,866, 8.10.19.

Drying chamber. E.P. 147,562. *See* XIII.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Development of electrical conductivity in —— and its variation as a result of heating. F. Fischer and G. Pfleiderer. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 394—408. Chem. Zentr., 1921, **92**, II., 521—522. (*Cf.* Sinkinson, J., 1920, 591 A.)

COAL, peat, lignite, and wood when carbonised all develop an appreciable electrical conductivity at the same temperature, *viz.*, 700°—750° C. The change of conductivity as a result of heating was explored up to a temperature of 1100° C. The temperature coefficient of conductivity was greater with the moderately heated specimens than with the more highly heated specimens. The low-temperature (up to 600°) carbonisation products of the different fossil coals were all in the same condition as regards electrical conductivity. The results suggest a means for distinguishing between low and high temperature cokes, for determining their temperature of carbonisation, and for controlling the uniformity of heating in the charge of coke ovens. —H. J. H.

Coals; Methods for the identification and valuation of ——. F. S. Sinnatt. J. Soc. Dyers and Col., 1921, **37**, 108—113.

A KNOWLEDGE of the agglutinating power of a coal (J., 1920, 83 T) enables the consumer to compensate for the variation in caking power by varying the amount of coke mixed with the coal, or by varying the size of the particles of the coke breeze, so as to ensure efficient combustion of the coal in steam raising. The rate of combustion of the coal can be modified by the addition of water (up to 8%) prior to introduction into the grate. A further factor in efficient combustion is the average actual size of the pieces of coal.—W. P.

Lignites; Some constituents of ——. R. Ciusa and A. Galizzi. Gazz. Chim. Ital., 1921, **51**, I., 55—60.

THE xyloid lignite of Fognano, near Montepulciano, contains a hydrocarbon, $C_{15}H_{20}$, m.pt. 61°—62° C., b.pt. 314°—316° C., or 208°—210° C. at 23 mm. pressure, which represents a new mineral species and is named simonellite; and also three unsaturated hydrocarbons: $C_{15}H_{28}$, b.pt. 222°—228° C. at 25 mm.; $C_{15}H_{28}$, b. pt. 240°—244° C. at 25 mm., and $C_{15}H_{26}$, b.pt. 253° C. at 25 mm. A lignite deposit near Terni contains a hydrocarbon, $C_{20}H_{34}$, m.pt. 74°—75° C., which is possibly identical with hartite. The material known commercially as Forli lignite has more the character of peat and contains lignoceric acid. (*Cf.* J.C.S., May.)—T. H. P.

Tar; Increase in yield and quality of —— by cooling the crude gas between the retort and hydraulic main. Binder. Gas- u. Wasserfach, 1921, **64**, 129—130.

IN the experimental apparatus used the gas was sprayed with the ammoniacal liquor in the horizontal offtake to the hydraulic main. It was then passed through a tar separator, a cleaning tower packed with cotton wool, and a tower packed with ferric oxide. The water from the main was led off into two tanks, from the second of which it ran to waste quite clear and from the first of which the tar could be drained off and any scum removed. With the adoption of spraying, 60·3% of the tar was recovered in the hydraulic main, whilst without spraying the quantity recovered in the main was 19·3% of the total. From one ton of coal there was obtained by spraying 41·1 kg. of tar, whilst without spraying there was obtained only 32·8 kg. of tar and 4·6 kg. of pitch. It is claimed that such spraying prevents the formation of pitch in the mains, and the quality of the tar is improved.—A. G.

Gases; Behaviour of explosive mixtures of —— at low pressures. A. Stavenhagen and E. Schuchard. Z. angew. Chem., 1921, **34**, 114—115. (*Cf.* J., 1920, 812 A.)

THE critical pressure depends on the diameter of the explosion tube; as the diameter increases the critical pressure decreases. This is due to the greater cooling effect of the walls of the larger tubes. When a spark is passed continuously through a mixture of oxygen and hydrogen maintained below the critical pressure at which explosion occurs, the gases combine slowly and without producing light.—W. P. S.

Ignition of gaseous mixtures by induction coil sparks; Phenomena of the ——. J. D. Morgan and R. V. Wheeler. Chem. Soc. Trans., 1921, **119**, 239—251.

MEASUREMENTS of the minimum currents ("igniting currents") required in the primary to produce sparks in the secondary of an induction coil at a gap of constant width capable of igniting mixtures in various proportions of methane and air, indicated that the igniting current increases as the percentage of methane in the mixture increases or decreases

on either side of a critical value of 8·2—8·4%. The voltage of the sparks bears a similar relation to the methane percentage, as does also the width of the igniting gap with a constant current of 1 amp. in the primary, so that the energy represented by a given igniting gap bears the same relationship to the mixture ignited as does the energy corresponding to the igniting current for that mixture. As, however, it was shown by thermal measurements made on the sparks that the total energy of the sparks bore a very different relationship to the percentage of methane in the mixture ignited, whilst the voltage of the sparks produced at given igniting gaps bore a relationship similar to that found in the ignition experiments, it is concluded that the igniting power of the induction coil sparks is to be ascribed to the energy of their "capacity components" only ($J_1 = \frac{1}{2}CV^2$), and not to their total energy. The assumption involved in this deduction, that ignition is essentially a thermal process involving the heating of a sufficient volume of the mixture to a sufficient temperature for a sufficient length of time, is shown to be justifiable.
—G. F. M.

Air-benzine mixtures; Determination of higher and lower limits of explosion of ——. W. Reinders. Chem. Weekblad, 1921, **18**, 157—159.

For determining the higher and lower limits of explosibility of air saturated with benzine vapour, an apparatus is used consisting of a wide glass tube, surrounded by a jacket containing water or a freezing-mixture, with two platinum wires fused in the top, and with its upper end terminating in a narrow tube with funnel and tap. The tube is connected with a levelling tube. The apparatus is first filled with water and a layer of benzine and a few c.c. of air are then introduced. After bringing the mixture to any desired temperature, the explosibility of the air-vapour mixture is tested by passing a spark through it. Results obtained with many benzine fractions are tabulated. With the light benzine fractions used in motor-cars air saturated with the vapour at temperatures above 0° C. is not explosible; on the other hand, the heavier fractions (b.p. 100°—200° C.; sp. gr. 0·74—0·75) may constitute a risk, and their displacement from storage reservoirs in garages should be effected by means of inert gases, such as nitrogen or carbon dioxide.
—W. J. W.

Paraffin wax; After-treatment of solution obtained in pressure oxidation of ——. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 94—100. Chem. Zentr., 1921, **92**, II., 522—523.

When preparing soaps by the pressure oxidation of paraffin wax (*cf.* Schneider, J., 1921, 290 A) the soda solution employed should be neutralised as completely as possible. The soaps can be separated by direct evaporation of the solution, or, better, by removing the supernatant layer of paraffin and allowing to stand over-night, when the salts of the fatty acids separate in the solid state. Brown soaps may be bleached by sodium hypochlorite or by further treatment in the autoclave at 160° C. Still more effective is treatment of the warm solution with acid or with carbon monoxide under pressure at 180°—200° C. The carbon monoxide, behaving as formic anhydride, liberates free fatty acids with the production of sodium formate. This may be converted into formic or oxalic acid or calcined to regenerate the sodium carbonate originally used. The fatty acids precipitated may be purified by distillation either with superheated steam or *in vacuo*. Neutral substances remaining are removed by distillation under diminished pressure at 250° C., followed by extraction with benzene in the cold. In the preparation potash or mixtures of potash and soda may replace sodium carbonate to give correspondingly different types of soap. All the soaps lather well.—H. J. H.

Colorado shale oils; Investigation of ——. A. J. Franks. Chem. and Met. Eng., 1921, **24**, 561—564.

Shale oils from the low-temperature carbonisation of shales from various strata were distilled, and each 10% (by vol.) of the distillate was examined separately. Curves plotted to show the relation between temperature and percentage distilled show a similarity in character of the oils; a sharp bend occurs at 350°—360° C., representing the temperatures between which cracking occurs, although this takes place slightly even at 300° C. Curves obtained with composite samples from the secondary and primary condensers indicate that it is not possible to condense the oil vapours fractionally with success. Specific gravity curves confirm the similar general character of the oils. Saturation (percentage of volume not attacked by sulphuric acid) decreases with increase in boiling point and specific gravity, up to the point where cracking begins, and it is remarkable that cracking of unsaturated oils in the heavy fractions produces lighter oils of higher saturation. This phenomenon is so far without adequate explanation.—W. J. W.

Decomposition of hydrocarbons. Kohlschütter and Frumkin. *See* III.

Gas from strawboard factory waste waters. Hermann. *See* V.

Patents.

Peat; Process for dehydrating ——. E. Laaser and C. Birk. G.P. 331,692, 28.12.19.

The peat pulp is heated under pressure which is then released. Evolution of moist vapours occurs and the vapours are compressed and used for the drying of the peat pulp. As a result of the compression the vapours acquire a temperature somewhat higher than that of the liquid in the peat pulp, and this temperature difference is sufficient for evaporation of the liquid.—H. J. H.

Coke ovens. E. Hurez. E.P. 153,272, 12.3.20. Conv., 29.10.19.

A regenerative coke oven is adapted to be heated either by rich gas from the oven itself or by producer gas or blast-furnace gas. Two adjacent superposed sub-flues establish communication between the heating flues of the oven and two series of regenerating chambers, the arrangement being such that when the oven is heated with poor gas all the even chambers serve alternately for the passage of the waste gases and for the preheating of the air, and the odd chambers serve alternately for the passage of the waste gases and for the heating of the poor gas. When rich gas from the oven is used, the air necessary for combustion is heated by the entire series of regenerating chambers.
—A. G.

Coke ovens. Foundation Oven Corp. E.P. (A) 160,625 and (B) 160,626, 29.1.20, and (C) 160,628, 30.1.20.

(A) The regenerator, which is located in the sole of the oven, consists of an air passage of narrow rectangular cross-section returning parallel to itself once or several times along the whole length of the sole, and having one of its wide faces in close proximity to a waste gas passage for the whole or part of its length. One or several superposed waste gas passages are in close proximity to, and surrounded laterally by, the air passages, which pass back and forth in the same horizontal plane as the waste gas passages. The flues in

adjacent rows are so arranged that the combustion flues in one row are opposite the waste gas flues in the adjacent rows, so as to distribute equally the heat throughout the oven. Two waste gas flues correspond to each combustion flue, one of the former being placed on either side of the latter. (B) A regenerator and gas preheating duct system are provided for each row of flues. The gas preheating ducts can be cut out and air and hot waste gases can be conducted alternately through a common horizontal flue in the sole of each coking chamber, which flue communicates with alternate flues in the two heating walls of the coking chamber. Two gas ducts under each heating wall are connected with alternate combustion flues in each wall. Each regenerator is divided longitudinally into two superposed portions and communicates with the common air or hot gas flue at the outer end of the oven only. The gas admission and discharge ends of the preheating ducts are exposed in front of the oven and are adapted to be easily connected respectively with a gas main and with a gas duct leading to alternate combustion flues or to be closed altogether. A three-way valve is provided outside the oven which can open communication of the discharge end of the gas preheating system with either of the two gas ducts leading to the combustion flues of each heating wall. The combustion flues are staggered, so that the vertical combustion flues in one heating wall are opposite the vertical hot gas flues in the adjacent heating walls. Each pair of combustion flues is provided with a separately adjustable valve by which the quantity of air can be adjusted separately at successive points along the line of the combustion flues so as to control the distribution of heat along this line. The air from the horizontal flue can be admitted to each pair of combustion flues independently. (C) The coke oven has combustion flues, gas ducts, and a preheating passage for the gas, the outer ends of the gas ducts comprising a box or casing providing two chambers in communication with the respective gas ducts and having ports opening communication between the respective gas ducts and the preheating passage. The ports are provided with valves, and a single device on the outside of the oven is provided for operating the valves alternately.—A. G.

Gas; Method of manufacturing ——. W. D. Wilcox. U.S.P. 1,372,731, 29.3.21. Appl., 1.4.18.

The plant comprises two vertical cross-connected retorts disposed above and discharging into two corresponding generators. One of the generators is blown with air and the blast gases are conveyed through a valve into heating flues adjacent to the retorts. A partial vacuum is concurrently created at an outlet in the lower portion of the second generator sufficient to draw the gases and vapours distilling off in the retorts through the preheated material in the second generator and through the outlet. The second generator is then subjected to an air blast and the process repeated, using alternate generators and retorts. A maximum pressure is maintained within the plant at a point in the lower portion of the retort above the generator in blast.—A. G.

Gas producer. J. C. Miller and A. Isles, Assrs. to The W. R. Miller Co. U.S.P. 1,373,443, 5.4.21. Appl., 14.6.19.

The cylindrical body and ash-pan of the producer are revolved at the same rate and in the same direction. The body carries a grate which is inclined inwards and surrounded by a stationary bustle pipe, water troughs sealing the joint between the bustle pipe and the body portion. The blast devices extend through the bustle pipe.—A. G.

Gas; Method of producing ——. L. W. Bates. U.S.P. 1,373,704, 5.4.21. Appl., 19.2.20.

A mixture of a liquid hydrocarbon and a pulverised solid fuel is injected into a mixture of air and steam in a generator heated to a temperature sufficient to transform the particles of solid carbonaceous substance and the liquid hydrocarbon into gas. The ash is removed from the gas, which is then washed with a liquid hydrocarbon to remove tar and carbon.—A. G.

Chamber oven plant. H. Bröcker. G.P. 330,347, 17.4.19. Addn. to 315,099 (J., 1920, 478 A).

The producers are first heated with coke and then charged with coal which is carbonised by heat from the coke below, which after some degree of cooling is withdrawn. The producers thus behave as gas retorts—a convenience in small installations.
—H. J. H.

Distillation of coal; Apparatus for ——. A. Niewerth. G.P. 331,508, 24.8.12.

A central vertical retort is provided with two inclined heating chambers, one at each side, containing coal or coke, used as fuel. The free spaces of the side chambers and of the central retort are in communication and one side chamber is connected with the top of the retort, the other with the bottom. Producer gas developed by a blast in one side chamber is passed from the top of the inner retort to the bottom and thence into the hot coal in the other side chamber. The process can be reversed so as to maintain a continuous distillation.
—H. J. H.

Vertical retort for continuous carbonisation of coal. Rombacher Hüttenwerke, and J. I. Bronn. G.P. 332,102, 14.7.18.

Most coking coals, when being carbonised, have completed the stage of melting, caking, and swelling by about one-quarter to one-third of the time for complete coking. Afterwards no further change in dimensions occurs, and if an enlargement of the sectional area of the retort is made at the point where this stage is reached, the hanging up of the charge can be prevented.—H. J. H.

Gas-making furnace. B. Ludwig. G.P. 332,103, 31.3.18.

The furnace is provided with superposed heating flues in which gas and air are led separately, but the flues are perforated so as to permit a gradual admixture and combustion and divided into two groups in which the heating gases travel in opposite directions. Gradual combustion and even heating of the furnace are achieved.—H. J. H.

Fuels; Treatment of dusty, bituminous —— for recovery of nitrogenous by-products by carbonisation. "Gafag," Gasfeuerungsges. Wentzel und Co. G.P. 332,507, 5.8.19.

The fuels are "briquetted" by means of sodium silicate, whereby the passage of gases through the charge during carbonisation is facilitated.
—W. J. W.

Low-temperature tar; Method for producing tar of aliphatic compounds or —— [in gas producers]. G. A. Pestalozzi. E.P. 145,408, 9.6.20. Conv., 20.6.19.

Immediately above the fuel bed in a gas producer a cooling zone is established, the temperature of which is kept below 400° C. by injecting water, steam, gases or the like, whereby detrimental decomposition of the gases and vapours produced in the distilling zone of the generator is avoided.
—A. G.

Mixed gas from the distillation of coal and of wood, peat, or lignite; Production of ——. C. O. Rasmussen. G.P. 332,057, 17.11.18.

The gases are not mixed until the tars have been separated and then the mixture goes through the customary purification processes. Whereas in coal gas tars basic compounds predominate, in tars from wood, peat, etc. acid constituents are in excess. If the crude gases are mixed stoppages occur readily, while the tars are commercially more valuable when separate than when mixed.—H. J. H.

Gas; Production of lighting and heating —— from bituminous shale. E. von der Burchard and A. Rau. G.P. 332,155, 22.5.19.

Crude gas obtained in the distillation of shale is passed through a layer of red hot carbonaceous material, *e.g.*, coke or charcoal, contained either in the retort or in a separate "cracking" chamber. Oils are thereby cracked to form permanent gas, and carbon dioxide from the shale is reduced to carbon monoxide. A comparatively high-grade gas (310—400 B.Th.U. per cub. ft.) is produced.—H. J. H.

Blast-furnace and generator gases; Purification of ——. N. Klärding. E.P. 153,263, 28.10.20. Conv., 31.10.19.

The crude gas is passed through granular material, which moves continuously downward through an enclosed chamber, and the dust is removed from the material by passing a branch stream of purified gas through the material in an auxiliary chamber, into which the material is discharged by a shaking screen in the lower part of the main chamber.—A. G.

Hydrogen sulphide [in producer and coke-oven gases]; Oxidation of ——. W. Schumacher. G.P. 331,287, 6.3.17.

The hydrogen sulphide in producer gas, coke-oven gas, and the like is oxidised to sulphur and oxides of sulphur by passing the gas mixture, together with the requisite amount of air, over charcoal which is heated to a temperature below that at which the gas ignites. The process can be carried out at 100° C.; the charcoal remains unchanged and the sulphur deposited on it can be recovered afterwards without difficulty.—J. H. L.

Iron oxide solutions; Preparation of stable, alkaline —— for gas purification. Badische Anilin- und Soda-Fabr. G.P. 333,755, 3.4.18.

The addition of a small quantity of a disinfectant, *e.g.*, phenol, cresol, naphthol, or crude tar, to the alkaline solution prevents decomposition by bacteria of the organic compounds, such as tartaric acid or oxalic acid, added to keep the iron compounds in solution.—L. A. C.

[Alcohol] distillation process. E. W. Stevens, Assr. to Chemical Fuel Co. U.S.P. 1,372,465, 22.3.21. Appl., 9.3.20.

Commercial aqueous alcohol is mixed with a hydrocarbon oil and fusel oil and the mixture is redistilled to obtain a fraction consisting mainly of alcohol and substantially free from water, for use in making composite motor-fuels.—A. R. P.

Shale and the like material; Method of and apparatus for treating ——. L. B. Ard. U.S.P. 1,373,698—9, 5.4.21. Appl., 3 and 4.2.21.

The shale is conveyed to the bottom of a cylindrical retort containing molten metal by a helical vertical conveyor, concentric with a helical vane surrounding the conveyor which retards the upward flow of the shale, so that the whole of the volatile matter is evolved during the upward movement of the shale through the molten metal.—A. G.

Oil-shale retort. F. Jones. U.S.P. 1,373,890, 5.4.21. Appl., 29.5.18.

A continuous retort for the destructive distillation of oil-sands and oil-shale comprises a series of superposed intercommunicating annular hearths, combustion or heating chambers interposed between the hearths, the floors of the latter constituting the roofs of the combustion chambers, a central hollow shaft with hollow arms and rabbles for advancing the material from one hearth to another, and means for supplying steam to the shaft and arms, the latter being perforated to allow steam to be directed on to the material under treatment.—A. de W.

Petroleum; Extraction of —— from oil-bearing sands and rocks. W. Horwitz. G.P. 332,100, 1.4.19.

The material is heated in a suitable vessel by pressure water or live steam, which is introduced tangentially or at an angle to the sides for preference. The mixture of oil-sand and hot water passes through the vessel without losing pressure. Substances are introduced either continuously or intermittently to facilitate extraction, *e.g.*, benzene, toluene, common salt, sodium sulphate, etc. —H. J. H.

Hydrocarbons; Apparatus for cracking ——. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,372,937, 29.3.21. Appl., 22.5.17.

A horizontal cylindrical cracking still is provided with rows of scrapers in staggered relation attached to an oscillating frame provided with journals at the horizontal axis of the still. All the scrapers slide in the frame and fall by gravity, so as to be continually in contact with the still bottom for the purpose of removing coke deposits.—L. A. C.

Petroleum products; Method of distilling ——. C. Kroll. U.S.P. 1,373,251, 29.3.21. Appl., 11.4.18.

The vapours obtained by distilling the hydrocarbons percolate through a body of absorbent material contained in a chamber insulated to prevent loss of heat. The vapours of the high-boiling hydrocarbons are extracted in the chamber, and the remaining vapours are condensed.—L. A. C.

Hydrocarbon oils; Treating ——. D. T. Day. U.S.P. 1,373,391, 29.3.21. Appl., 30.4.18.

A mixture of high-boiling hydrocarbon oils and petroleum residues having a higher cracking point than the oils is subjected to heat treatment above 600° F. (315° C.), but below the temperature necessary to crack the residues. Low-boiling hydrocarbons are separated from the product, and the residues are added to a further quantity of the high-boiling oil.—L. A. C.

Gasoline from crude oil; Process for the production of ——. *Process for the production of hydrocarbons of low boiling-points from hydrocarbons of high boiling-points.* P. Danckwardt. U.S.P. (A) 1,373,653 and (B) 1,373,654, 5.4.21. Appl., 27.8.17.

(A) Material containing high-boiling hydrocarbons is caused to react with a heated mixture of carbon, a halide, and a metal, and fractions of low and high boiling points are condensed separately from the vapours. (B) Air and steam are passed through an ignited mixture of carbon, nickel, and nickel chloride, hydrocarbon oil is added to the mixture, and the vapour generated is passed through a mixture of oil with carbon, nickel chloride, and nickel. That portion of the vapour which boils at or below 150° C. is condensed separately from portions boiling at higher temperatures.—L. A. C.

Catalysis; Process of ——. E. W. Stevens, Assr. to Chemical Fuel Co. of America. U.S.P. 1,374,119, 5.4.21. Appl., 18.3.20.

In the catalysis of gaseous carbon compounds by means of hot metallic catalysts which are used under conditions whereby carbon would be deposited, the surface of the catalyst is sparked during the process.—A. J. H.

Hydrocarbons such as petroleum spirit; Production of light ——. Allgem. Ges. für Chem. Ind. m.b.H. G.P. 333,168, 5.12.17.

The oils obtained by distilling petroleum or lignite tar are purified by treatment with liquid sulphur dioxide, and are then distilled with aluminium chloride, yielding 70% or more of light petroleum spirit.—L. A. C.

Petroleum oils; Recovery of —— from the acid resin obtained in refining petroleum. Harburger Chem. Werke Schön und Co. G.P. 333,169, 11.12.18.

The acid resin, after removal of free acid, is dried and agitated at 120°—125° C. with concentrated sulphuric acid. The product on distillation yields a moderately high boiling oil which can be employed for lighting or heating, as a lubricant, or for other purposes. The residual resin, which has a higher m.p. than the original material, is suitable for use as an insulator.—L. A. C.

Still for cracking or distilling hydrocarbons, tar, or the like. A. Sommer. G.P. 333,216, 21.10.15.

A metal still is provided with a close fitting, thin-walled metallic lining which can be replaced when encrusted with carbon deposits.—L. A. C.

Lubricating oil; Production of —— from wood tar. O. de F. Skibsted. G.P. 330,276, 27.6.19.

The fractions boiling above 250° C. are neutralised with powdered lime, oxidised by a current of air, and then distilled. The treatment can be carried out in the tar still and during the distillation, which is interrupted for the purpose.—H. J. H.

Lubricants; Production of —— from tar distillates. Verkaufsvereinigung für Teererzeugnisse G.m.b.H., and F. Schreiber. G.P. 330,970, 24.6.19.

The heated tar oil is treated with sulphur in presence or absence of air. Anthracene and phenanthrene are thereby converted into soft, pitchy substances, which increase the lubricating properties of the oil. Lubricants for axles, ropes, and briquette-rolls can be prepared in a similar manner from the crude anthracene press-cake alone or with addition of oils.—H. J. H.

Asphalt substitute; Production of ——. Harburger Chem. Werke Schön & Co., and W. Daitz. G.P. 330,650, 6.7.18.

Soft pitch is heated and stirred for a long time with a paste made by incorporating with water mineral matter such as magnesia, alumina, silicates of magnesium and aluminium, or precipitated iron oxide. A temperature of 110°—115° C. is maintained, at which the water is evaporated and a product resembling Trinidad asphalt obtained.—H. J. H.

Montan wax; Process for saponifying —— with simultaneous bleaching of the soap produced. F. Fischer. G.P. 334,155, 18.3.19.

Crude or purified montan wax is heated below 160° C. and under increased pressure with aqueous solutions of bases or other compounds which combine with fatty acids, *e.g.*, sodium or potassium carbonate, in the presence of oxygen. By acidification of the solution a clear, hard, resinous product is obtained.—L. A. C.

Tar-extractor and scrubber for gas. J. Wells. U.S.P. 1,373,280, 29.3.21. Appl., 13.9.19.

See E.P. 153,109 of 1919; J., 1920, 813 a.

Hydrocarbons; Process of converting liquid —— into hydrocarbons of lower boiling point. W. M. McComb. E.P. 160,907, 24.12.19.

See U.S.P. 1,337,144 of 1920; J., 1920, 396 a.

See also pages (a) 346, *Hydrogen sulphide from gases* (G.P. 299,163 and 331,322). 356, *Emulsions* (U.S.P. 1,373,661). 359, *Tanning material* (G.P. 333,403). 367, *Waste water from gas-works* (G.P. 333,703). 369, *Fatty acids and aldehydes* (G.P. 332,478).

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

"Kelpchar," a new decolorising carbon. J. W. Turrentine, P. S. Shoaff, and G. C. Spencer. Science, 1919, **50**, 507.

Supplementing the work of Zerban (J., 1919, 527 a, 873 a) it was shown that a decolorising carbon of high activity could be produced in large quantity, the method of heating being of importance. Carbonising in one stage failed to yield a product of uniform quality, but by carbonising in two stages consistently satisfactory results were obtained. After leaving the retorts, the porous char was extracted with hot water to remove potassium chloride and iodide, the residue heated with dilute hydrochloric acid, washed with water to neutrality, and dried. The carbon obtained in this way compares favourably with "Norit."—J. P. O.

Patents.

Retort [for wood distillation]. H. M. Barr. U.S.P. 1,373,702, 5.4.21. Appl., 24.5.20.

A metallic shell lined with asbestos is divided by a false bottom of reticulated material into an upper retort chamber and a lower heating chamber. A pair of flues extends along the heating chamber for heating the retort, each flue including two stationary sections, one seated in one wall of the shell and leading to the source of heat, and the other seated in the opposite wall and leading to the stack. A "floating" flue section is suspended within the heating chamber between the stationary sections and is spaced from the walls of the heating chamber. The "floating" section consists of a split asbestos sleeve having a central convex portion, a split metallic sleeve having a corresponding convex portion, and clamping bands for securing the ends of the sleeve to the respective flue sections. —A. G.

Wood and other vegetable products; Recovery of volatile compounds from ——. E. Heuser. G.P. 332,298, 8.4.19.

The raw material is heated with inorganic acids at normal or elevated pressure, with or without the introduction of steam, and is afterwards subjected to dry distillation. A good yield of volatile organic compounds results without any reduction in the yield of tar or gases.—W. J. W.

Low-temperature tar; Apparatus for production of ——. G. de Grahl. G.P. 332,109, 19.3.19.

The raw material (coal, peat, or similar substances) is continuously forced or drawn through tubes enclosed in spiral heating flues, the tubes being arranged singly or in series. The products are delivered into a chamber, where separation of the gas from the solid residue occurs, so that the time of contact of gas and solid is reduced to a minimum.—H. J. H.

III.—TAR AND TAR PRODUCTS.

Hydrocarbons; Decomposition of —— by canal rays. V. Kohlschütter and A. Frumkin. Ber., 1921, 54, 587—594.

THE vapours of naphthalene, benzene, diphenyl, anthracene, phenanthrene, fluorene, decane, and petroleum have been subjected to the action of canal rays in a vessel so designed that the vapour can be passed at a desired pressure between an anode of aluminium wire and a specially constructed cylindrical cathode. In every case the latter becomes more or less rapidly coated with a deposit which ultimately is of sufficient thickness to impede the passage of the current. The properties of the deposit depend on the potential of the cathode and not on the mode of union of the carbon in the decomposed product. With low potentials the deposits are transparent and coherent, and evolve large quantities of gas and tar when heated; at higher potentials they consist of practically pure carbon, which closely resembles anthracite in appearance. Graphite does not appear to be formed. (*Cf.* J.C.S., June.)—H. W.

Phenols; Pressure oxidation of ——. F. Fischer and H. Schrader. Ges. Abhandl. Kennt. Kohle, 1919, 4, 293—309. Chem. Zentr., 1921, 92, II., 606—607.

THE oxidation of phenols by air under 45 atm. pressure was examined to see if resinous substances were obtainable, with the ultimate object of producing substances similar to bakelite from the phenols of low-temperature tar without the use of formaldehyde. The products obtained were partly insoluble condensation products and partly degradation products. Under suitable conditions fairly clear resinous substances were obtained, the colour being dependent on the reaction and concentration of the original mixture. Phenol at 100° C. in presence of a 2·5 N soda solution yielded a considerable quantity of brown resinous product, but less at 150°—200° C. The three isomeric cresols were oxidised in presence of soda solution and *o*-cresol in presence of an excess of sodium hydroxide. Colouring matters and degradation products were obtained, but little resinous matter. The colouring matters were apparently fuchsine derivatives resulting from condensation of cresol and aldehydes. In presence of $N/1$ H_2SO_4 above 150° C. *o*-cresol was extensively oxidised, yielding solid products. At 150° C. the products were a hard, lustrous, orange-coloured resin, soluble in benzene and alcohol, and also a brown substance insoluble in benzene, and small quantities of colouring matter.—H. J. H.

Naphthols and naphthylamines; Reaction of —— with bisulphite. P. Friedländer. Ber., 1921, 54, 620—624.

THE reactivity of naphthols with bisulphite has been considered by Bucherer to be due to the intermediate formation of highly reactive naphthyl sulphites, but this view is not in harmony with the established properties of these substances. It is simpler to assume that the naphthols react in the tautomeric ketonic form, and that the products are normal ketone bisulphite additive compounds. Evidence in favour of this view is found in the observation that hydroxynaphthoic acid and bisulphite react with *as*-methylphenylhydrazine in exactly the same manner as with phenylhydrazine and yield N-methylnaphthophenocarbazole,

$$C_{10}H_6—N(CH_3)—C_6H_4.$$

This reaction is not possible if Bucherer's view be accepted. (*Cf.* J.C.S., June.)—H. W.

Toluenesulphonyl chlorides; Melting point of mixtures of o- and p- ——. L. Harding. Chem. Soc. Trans., 1921, 119, 260—262.

THE melting points of mixtures of pure *o*- and *p*-toluenesulphonyl chlorides in various proportions were determined and the melting point curve obtained. Following are some of the figures recorded: 0·0 % of *para*-isomeride, m.p. 10·17° C.; 10·0%, 5·8°; 17·5% (eutectic), 1·6°; 20·0%, 7·9°; 50·2%, 39·8°; 78·2%, 57·3°; and 100·0% of *para*-isomeride, 67·2° C. The pure *o*-toluenesulphonyl chloride was prepared by fractional precipitation of the *o*-sulphonamide from its sodium salt, hydrolysis of this substance to sodium *o*-toluenesulphonate, and treatment of the latter with phosphorus pentachloride. It had the following constants: b.p. 126° C. at 21 mm., sp. gr. 1·3383 at 20°/4° C., m.p. 10·17° C., n_D=1·5575.—G. F. M.

Dinitroanthraquinones. M. Battegay and J. Claudin. Bull. Soc. Ind. Mulhouse, 1920, 86, 628—631.

WHEN the crude product of the dinitration of anthraquinone is reduced the whole of the 1.5-, almost the whole of the 1.8-, and a large proportion of the 2.6-diaminoanthraquinone can be separated. The residue of mixed diaminoanthraquinones has been diazotised, converted into the corresponding dihydroxyanthraquinones, and separated into 2.6-, 1.8-, 1.6-, 1.7-, and 2.7-dihydroxyanthraquinones. Based on these results, it is calculated that the dinitration of anthraquinone yields 37% of 1.5-, 37% of 1.8-, 4·2% of 1.7-, 3·6% of 1.6-, 6% of 2.6-, and 4% of 2.7-dinitroanthraquinone. Dhar (J., 1920, 685 A) claimed that 1.2-, 1.3-, 2.6-, and 1.5-dinitroanthraquinones are formed by the dinitration of anthraquinone, and identified these products by conversion into the corresponding dibromoanthraquinones. Repetition of his experiments has led to the isolation of 1.5- and 1.8-dibromoanthraquinones, and has shown that the products regarded by Dhar as 1.2- and 1.3-dibromoanthraquinones cannot be homonuclear dibromoanthraquinones. (*Cf.* J.C.S., June.)—F. M. R.

Dibromoanthraquinones. M. Battegay and J. Claudin. Bull. Soc. Ind. Mulhouse, 1920, 86, 632—635.

THERE are ten possible dibromoanthraquinones, and that used by Graebe and Liebermann as the intermediate product in their classical synthesis of alizarin might be assumed to be the 1.2-derivative, but a study of various dibromoanthraquinones has shown that that is not the case. The dibromoanthraquinone of Graebe and Liebermann has been stated to be formed by the direct bromination of anthraquinone at 100° C. or by the oxidation of tetrabromoanthracene, but the two products are not identical. In the former case the product is 2.7-dibromoanthraquinone, yellow spangles, m.p. 252° C., whilst in the latter case, after many crystallisations from benzene and toluene, 2.3-dibromoanthraquinone, yellow needles, m.p. 283° C., is obtained. When 1.4-nitrobromoanthraquinone is reduced, the bromine is eliminated, and α-aminoanthraquinone is formed. (*Cf.* J.C.S., June.) —F. M. R.

PATENTS.

Tar oils; Production of pure —— from the crude oils. M. Melamid and L. Grötzinger. G.P. 332,112, 5.4.17. Addn. to 264,811 (E.P. 9856 of 1912; J., 1913, 820).

CRUDE tar oils, or fractions thereof, are treated with phosphoric acid or similar compounds in the cold, followed, if necessary, by distillation. Unsaturated hydrocarbons are polymerised and separate with the phosphoric acid as resinous masses.—H. J. H.

Phthalic anhydride; Manufacture of ——. A. Wohl. E.P. 145,071, 16.6.20. Conv., 28.6.16.

PHTHALIC anhydride is obtained by passing a mixture of naphthalene vapour with air or oxygen over a suitable catalyst maintained below 500° C. The gas mixture may conveniently be obtained by passing air through or over naphthalene at 100°—120° C., and a suitable catalyst is prepared by soaking pumice (18 pts.) in a solution containing vanadic acid (2 pts.), and drying. The best results are obtained when the contact mass is maintained at 320°—330° C.—G. F. M.

Diphenyl oxide; Process of forming ——. J. M. Johlin, Assr. to Semet-Solvay Co. U.S.P. 1,372,434, 22.3.21. Appl., 24.7.19.

A MIXTURE of sodium benzenesulphonate and sodium hydroxide in such proportions that a portion of the sodium benzenesulphonate remains uncombined is heated to produce sodium phenoxide, and the heating is continued at such a temperature that the sodium phenoxide combines with the unchanged sodium benzenesulphonate to yield diphenyl oxide. —L. A. C.

Nitrotetrahydronaphthalenes; Preparation of reduction products of ——. *Preparation of polycyclic, hydroaromatic hydrocarbons (octohydroanthracene and octohydrophenanthrene).* Tetralin Ges.m.b.H. G.P. (A) 333,157, 17.3.16, and (B) 333,158, 15.3.19.

(A) THE nitro derivatives of tetrahydronaphthalene, or its homologues, yield on reduction with different reducing agents not only the corresponding amines, but also intermediate reduction products, such as hydroxylamines, which by intramolecular conversion yield derivatives of *p*-aminophenol, azoxy-, azo-, and hydrazo-compounds, the last of which undergo the benzidine conversion. A mixture of 1- and 2-nitrotetrahydronaphthalene on reduction, *e.g.*, with tin or stannous chloride and hydrochloric acid, yields a mixture of the corresponding amines, which can be separated by fractional crystallisation of the hydrochlorides or the acetyl compounds; 1- and 2-acetaminotetrahydronaphthalenes melt respectively at 156°—158° C. and 105°—106° C.; 1-aminotetrahydronaphthalene is a colourless liquid when freshly distilled, b.p. 146° C. (12 mm.), and 2-aminotetrahydronaphthalene forms colourless crystals, m.p. 38·5°—39·5° C., b.p. 146°—147° C. (12 mm.). Pure 1-nitrotetrahydronaphthalene, prepared by partial reduction of 6 mols. of a mixture of the 1- and 2-nitro compounds with 10 mols. of hydrogen and subsequent shaking with acid to dissolve the amines, on reduction with sufficient zinc dust and alcoholic sodium hydroxide to give 4 atoms of hydrogen, yields 1-azotetrahydronaphthalene, which forms ruby red prisms from hot acetic acid, m.p. 175°—177° C., and can be converted by further reduction with zinc dust and sodium hydroxide to 1-hydrazotetrahydronaphthalene, m.p. 180°—182° C. This compound is readily oxidised to the azo compound, and on treatment with mineral acids gives 4.4′-diamino-1.1′-octohydrodinaphthyl. 4-Nitro-2-aminotetrahydronaphthalene, m.p. 94°—96° C., is prepared by nitrating 2-acetaminotetrahydronaphthalene, by reducing a solution of 1.3-dinitrotetrahydronaphthalene in boiling alcohol and ethyl acetate with sodium hydrosulphide, or by partial catalytic reduction of the dinitro compound; complete catalytic reduction of the dinitro compound with hydrogen at 125° C. under pressure yields 1.3-diaminotetrahydronaphthalene, b.p. 201°—203° C. (13 mm.) and m.p. 72°—74° C. A solution of 3-nitro-2-aminotetrahydronaphthalene in decahydronaphthalene on treatment with hydrogen at 150° C. under pressure, in the presence of nickel, yields 2.3-diaminotetrahydronaphthalene, m.p. 135°—136° C., which on boiling with acetic acid forms an iminazole, $C_{10}H_{10}\langle{}^{N}_{NH}\rangle C.CH_3$, of m.p. 251°—252° C. (B) A mixture of, *e.g.*, 1000 pts. of tetrahydronaphthalene and 15—20 pts. of aluminium chloride is heated for about 6 hrs. below 100° C. The product is washed with acidified water, and distilled. Benzene and unchanged tetrahydronaphthalene pass over in the first fractions, while octohydrophenanthrene, octohydroanthracene, and a polycyclic, hydroaromatic hydrocarbon distil respectively at 160°—170° C., 170°—180° C., and 230°—235° C. (11 mm.); these compounds on heating with sulphur or distillation with zinc dust yield respectively phenanthrene, anthracene, and an aromatic hydrocarbon of m.p. 168°—169° C. The octohydroanthracene has m.p. 72°—73° C., and is not identical with the compound previously described. The products or mixtures of the same are suitable for use as lubricants.—L. A. C.

See also pages (A) 339, *Still* (G.P. 333,216); *Lubricating oil* (G.P. 330,276); *Lubricants* (G.P. 330,970); *Asphalt substitute* (G.P. 330,650). 349, *Asphalt-like material* (G.P. 332,634).

IV.—COLOURING MATTERS AND DYES.

Halogenated indigos; Halogenated nitrobenzaldehydes and ——. L. C. Janse. Rec. Trav. Chim., 1921, 40, 285—317.

p-AMINOBENZALDEHYDE when brominated in solution either in dilute hydrochloric acid or in acetic acid gives an almost quantitative yield of 3.5-dibromo-4-aminobenzaldehyde. In this latter compound the amino group may be replaced more or less readily by chlorine, bromine, iodine, or hydrogen, and the products on nitration give substituted *o*-nitrobenzaldehydes, which may be converted by treatment with acetone and alkali into halogenated indigos (*cf.* Baeyer and Drewsen, Ber., 1882, **15**, 775; 1883, **16**, 2188). A whole series of such compounds is described. (*Cf.* J.C.S., June.)—W. G.

Auxochromes; Combined ——. H. Kauffmann. Ber., 1921, 54, 795—802.

SUCH auxochrome-like groups of atoms as exhibit increased auxochromic character on account of the presence in them of true auxochromes are termed combined auxochromes. Their properties are examined in the particular instance of the dimethoxystyryl group, the *p*-nitrophenyl residue being used as chromogen. The utility of styryl in this connexion depends on the immediate attachment of its ethylenic linkage to the benzene nucleus, since substances such as 4-nitro-2.4′-dimethoxychalkone are only feebly coloured. The whole dimethoxystyryl complex is to be regarded as a new auxochromic unit. The combined auxochromes, like the simpler ones, are able to facilitate fluorescence. (*Cf.* J.C.S., June.)—H. W.

PATENTS.

Hydroxyazo dyes; Manufacture of ——. G. T. Morgan, and British Dyestuffs Corp., Ltd. E.P. 160,848, 17.7.19.

DIAZOTISED *o*-aminophenols, *o*-aminonaphthols, and their nitro, sulphonic, and carboxyl derivatives are coupled with 4.6-diamino-1.3-xylene, yielding products which dye animal fibres brown shades in conjunction with metallic mordants.—L. A. C.

Azo dye. T. H. Leaming, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,372,439, 22.3.21. Appl., 27.2.20.

A DISAZO dye is claimed, having the probable formula $NH_2.C_6H_4.(4)N_2(2).C_{10}H_4((1)NH_2.(4)SO_3Na,(8)OH)$.

$(7)N_2.C_6H_4.(4)NHC_2H_3O$, which yields *p*-phenylenediamine and triamino-8-naphthol-4-sulphonic acid on saponification and reduction with stannous chloride and hydrochloric acid, and dyes cotton, wool, natural and artificial silk greenish-black shades which can be developed on the fibre.
—L. A. C.

Condensation products resembling indophenol; Preparation of ——. Act.-Ges. für Anilin-Fabr. G.P. 333,897, 28.11.16.

p-NITROSOPHENOL, *p*-nitroso-*o*-cresol, or *p*-nitroso-*o*-chlorophenol is condensed with a phenol alkyl ether which is not substituted in the para position to the alkoxy group, such as anisol, *o*-chloroanisol, phenetol, *o*-cresol ethyl ether, or resorcinol dimethyl ether, in the presence of sulphuric acid of about 60° B. (sp. gr. 1·71), or concentrated hydrochloric acid. The products separate from the acid solution as brown or red compounds, which are coloured blue by the addition of alkalis, dissolve in concentrated sulphuric acid to give blue solutions, and in aqueous sodium sulphide to give feebly coloured solutions which turn blue in the presence of air, and yield the corresponding leuco compounds on the addition of acids.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton and other textile fibres; Action of sea-water on ——. C. Dorée. Biochem. J., 1920, **14**, 709—714.

FABRICS of cotton and silk are destroyed by immersion in sea-water for three weeks, wool lasting somewhat longer. This destructive action is, in the case of cellulose, due to micro-organisms, and not to oxygen, light, or the salts present. In its nature it resembles the "mechanical" breakdown of cotton sometimes observed under the "beetling" process (*cf.* Cross, J., 1920, 58 A). If cotton is acetylated to the monoacetate stage so that its structural qualities are preserved, the resulting material is very resistant to sea-water. Cellulose acetate silk withstands the action of sea-water for months.
—J. C. D.

Fibrous materials; Molecular structure of ——. R. O. Herzog and W. Jancke. Umschau, 1921, **25**, 53—54. Chem. Zentr., 1921, **92**, II., 573.

FROM experiments with Röntgen rays it is concluded that in plant fibres the cellulose is present in a crystalline form disposed symmetrically with respect to the axis of the fibre. Artificial silk consists of an irregular felted mass of crystalline fragments of unchanged cellulose; artificial silk made from cellulose acetate is amorphous and consists of a mixture in which the cellulose acetate has undergone considerable degradation. Natural silk shows a crystalline character and a similar symmetrical structure to that of cellulose. Animal hair is amorphous, and probably consists of two or more substances. Starch and pure fats are crystalline.
—J. H. L.

Polysaccharides. III. Cellulose. P. Karrer and F. Widmer. Helv. Chim. Acta, 1921, **4**, 174—184.

COMPARISON of the yields of cellobiose octo-acetate obtained by treating cellulose, cellobiose, methylcelloside, cellulose triacetate, cellobiose acetate, and methylcelloside acetate with acetic anhydride and sulphuric acid under similar conditions leads to the conclusion that cellulose must contain at least about 50%, and possibly more, of ready-formed cellobiose complex. Hess and Wittelsbach's formula for cellulose (J., 1920, 512 A) cannot, therefore, be accurate, as it indicates only 33% of pre-formed cellobiose. Methylation of cellobiose by means of alkali and methyl sulphate gives unsatisfactory results, but methylation of methylcelloside in this way gives an almost quantitative yield of hexamethylmethylcelloside. The latter may be further methylated, by means of dry methyl iodide and silver oxide, to heptamethyl-β(?)-methylcelloside, and hydrolysis of this by boiling 5% hydrochloric acid solution yields products from which β-tetramethylglucose may be isolated. (*Cf.* J.C.S., May.)
—T. H. P.

Cellulose. III. Asymmetric structure of cellulose and the influence of ammoniacal copper hydroxide [Schweizer's reagent] on the rotation of carbohydrates. K. Hess and E. Messmer. Ber., 1921, **54**, 834—841.

LEVALLOIS' observation that solutions of cellulose in ammoniacal copper hydroxide solution are optically active is confirmed, and the activity is proved to be due to the cellulose content. Under slightly varying conditions the values [α]=ca. −950° and −1000° are found, but accurate work is particularly difficult with the blue light. On the other hand, the "regenerated" cellulose is optically inactive in concentrated hydrochloric acid solution, as are also ethereal solutions of ethylcellulose, aqueous alkaline solutions of xanthate (viscose) cellulose, and jellies of cellulose in neutral salt solutions. Cellulose presents, therefore, a marked example of "latent asymmetry," thus resembling mannitol, and it appears that ammoniacal copper hydroxide behaves towards it in the same manner as boric acid or borax to the simpler carbohydrates. (*Cf.* J.C.S., June.)—H. W.

Cellulose. K. Freudenberg. Ber., 1921, **54**, 767—772.

CELLOBIOSE octa-acetate can be isolated in yield corresponding with the presence of 35—36% of cellobiose in the original material in a single operation when cellulose is treated with a mixture of acetic anhydride and concentrated sulphuric acid at a low temperature, the operation requiring about 14 days. An indirect estimation of the loss of octo-acetate which occurs during the change makes it probable that cellulose is composed of cellobiose to the extent of more than 60%. This result is not in harmony with Hess's conception of cellulose (J., 1920, 512 A) as composed of pentaglucosidylglucose residues, but is in agreement with the hypothesis that it is built up of cellobiose residues arranged in a uniform polysaccharide chain of ten or more members. (*Cf.* J.C.S., June.)—H. W.

Wood cellulose [; Action of sodium hydroxide on ——]. W. G. Harding. J. Phys. Chem., 1921, **25**, 201—203.

THE product remaining after heating wrapping paper with 1% sodium hydroxide solution at 100° C. amounted to about 60% of the original material, although absolute equilibrium was not reached even after 30 hrs.' treatment. With 6% sodium hydroxide the same result was obtained in about 6 hrs. Lignocellulose could be detected in the material after treatment.—W. J. W.

Pinewood; Content of soluble carbohydrates in ——. S. Schmidt-Nielsen. Tekn. Ukeblad, 1920, **67**, 354—355. Chem.-Zeit., 1921, **45**, Rep., 32.

PINEWOOD felled in the spring was finely rasped, and after extraction with ether was repeatedly extracted by alternate boiling with water or 0·3% acetic acid and treatment with alcohol. By more than 20 successive extractions a yield of soluble matter was obtained equal to 12·04% of the original wood or 13·9% of the dry substance. In determinations of reducing sugar by Kjeldahl's method 1 g. of the dried extract, before inversion, reduced 0·1898 g. of copper, and after inversion with 2%

[hyd]rochloric acid it reduced 0·6165 g. of copper. A [subs]tantially similar extract was obtained from [...]wood felled in the winter, but the yield in this [case] was only one-seventh of that mentioned above. [Pen]tosan determinations on the extract indicated [abou]t 23% of xylose.—J. H. L.

[Lig]nified cell membranes; Contribution to the know[le]dge of ——. P. Casparis. Pharm. Monats., [1]920, 1, 121—129, 137—146, 153—160. Chem. Zentr., 1921, 92, II., 584.

LIGNIFIED cell walls may be distinguished from those consisting of unaltered cellulose by means of a 15—40% solution of cobalt thiocyanate which colours lignified membranes blue. The reaction is probably due entirely to adsorption; it is more sensitive and trustworthy than Maule's permanganate reaction or the phloroglucinol-hydrochloric acid test.—J. H. L.

[Sulphite] pulp; Automatic cooking control for chemical ——. C. H. Allen. Techn. Assoc. Pulp and Paper Ind., 1920, III, 19—21.

IT is suggested that by controlling automatically the digestion of sulphite pulp, an increase in production will be obtained, together with an improvement in the quality. The control system described consists essentially of a power-driven steam valve, electrically connected with a steam flow meter on the digester steam line, an automatic relief valve, and relief strainers.—J. C. K.

Sulphite and sulphate [pulp] fibres; Tests for unbleached ——. R. E. Lofton and M. F. Merritt. Techn. Assoc. Pulp and Paper Ind., 1920, III, 1—7.

FOR distinguishing between unbleached sulphite and sulphate (kraft) pulps, the use of a mixture of 1 pt. of a 2% aqueous solution of Malachite Green and 2 pts. of a 1% solution of Fuchsine (Magenta), is recommended. The solutions, which should be used not more than a few hours after being mixed, should be tested with a standard mixture of sulphite and sulphate fibres. The colour contrast not only enables the presence of one or both of these fibres to be detected, but is sharp enough to allow of an approximately correct estimate of the percentages of the two kinds of fibres to be made. —J. C. K.

Paper; Measurement of translucency and opacity of ——. R. Fournier. Paper, Feb. 9, 1921, 32, 44.

THE translucency and opacity of paper can be measured by an apparatus in which the eye of the observer is replaced by a selenium plate which forms part of an electric circuit; the electrical resistance of the selenium varies according to the amount of light which it receives at the time the determination is made. By a slightly modified form of the apparatus the reflecting power of a sheet of paper may also be determined.—J. C. K.

Strawboard factory waste waters; Gas from ——. A. Hermann. Het Gas, 1920, 40, 131—135. Chem.-Zeit., 1921, 45, Rep., 32.

A COMMISSION appointed by the Dutch Government recommends storage in settling tanks followed by irrigation treatment or filtration as the best and cheapest means of purifying the effluent from strawboard factories. In a pulp factory employing this process it has been found that in absence of air the effluent undergoes a fermentation due to rodlet bacteria which, at an optimum temperature of 35° C., produce a gas containing 23—30% of carbon dioxide and 70—77% of methane. One volume of effluent evolves 2 volumes of gas, which is collected in bell covers, conducted to a gas holder and employed for the production of electric current for power and lighting in the factory, and the surplus is taken by the local gas works and mixed with coal gas in the proportion of 25%. An analysis of the gas showed carbon dioxide 24·7%, methane 64·3%, other hydrocarbons 0·6%, hydrogen 4·9%, oxygen 0·4%, nitrogen 5·1%; it contained traces of carbon bisulphide but no hydrogen sulphide or carbon monoxide.—J. H. L.

Sulphite spirit. Sieber. *See* XVIII.

PATENTS.

Fibres suitable for spinning; Method for producing —— *from papyrus.* J. J. Gähler. E. P. 144,249, 31.1.20. Conv., 3.6.19.

PAPYRUS, which has been retted in the usual manner, is subjected to a mechanical alternating right and left-hand twisting movement whereby the fibres are loosened. The attached substances are then removed by brushing and combing, and also by means of a second retting treatment, if a very clean fibre is desired.—A. J. H.

Wool; Process for producing spun material resembling —— *from viscose solutions.* Glanzfäden A.-G. E.P. 152,351, 13.11.19. Conv., 15.8.18. Addn. to 135,205 (J., 1921, 254 A).

IN the preparation of viscose solutions, as described in the chief patent, aerial oxidation of the cellulose takes place. This is prevented by the addition of about 5% (on weight of cellulose) of sugar (preferably cane sugar) to the aqueous caustic soda solution in which the cellulose xanthate is dissolved. —A. J. H.

Lace, fabrics and the like; Fireproofing, metallising, and waterproofing ——. A. Norweb. E. P. 160,627, 30.1.20.

LACE or fabric is padded with an emulsion formed from a solution of sodium silicate and sodium biborate, a metallic powder, and a solution of rubber in naphtha and amyl acetate, and is then dried. —A. J. H.

Artificial silk thread; Production of ——. G. F. J. Bouffe. E.P. 160,859, 3.9.19.

CELLULOSE threads which issue from a squirting nozzle are immediately drawn through a chamber which is exhausted of air or contains such gases as sulphur dioxide, carbon dioxide, etc., or through which a current of air is drawn, and are then wound on spools. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 28,733 of 1904, 14,087 of 1906, 11,729 and 24,707 of 1910, and 10,857 of 1915; J., 1905, 1299; 1906, 844; 1910, 1004; 1911, 126; 1916, 533.)—A. J. H.

Cellulose fibres; Production of easily bleached ——. B. Possanner von Ehrenthal. G.P. 331,802, 8.8.19.

MATERIAL such as flax or hemp straw, jute, reeds, nettles, potato haulms, willow bark, or the like, with or without a preliminary mechanical treatment, is treated at 40°—50° C. with a 0·5 to 2% solution of an organic or inorganic acid or acid salt to hydrolyse the binding material, and is subsequently heated, under normal or increased pressure, with a weak alkaline solution containing a small proportion of an organic solvent such as alcohol, carbon bisulphide, acetone, petroleum, higher hydrocarbons, or the like. The individual fibres are separated from the fibrous product by steeping in a warm solution or emulsion of fatty or oleic acids, or their salts, esters, sulphonic acids, or amides.—L. A. C.

Bast; Production of —— *from fibrous plants.* Nessel-Anbau-Ges.m.b.H. G.P. 331,896, 2.2.18.

THE bast is loosened without destruction of its

natural ribbon or tubular form by the action on the plant (ramie, nettles, reeds, hops, flax, etc.) of water or a solution of sugar (molasses), and is subsequently separated into fibres by mechanical and chemical means.—L. A. C.

Fibres from the needles of pines and other conifers; Production of textile ——. R. Guttmann and J. Siegert. G.P. 332,096, 8.5.19.

THE dried needles are heated to 60°—70° C. in dilute mineral acid to loosen the epidermal silicious layer, and resinous material is removed from the fibres by subsequent treatment with a 3% solution of alkali. The alkaline resin solution can be employed for sizing paper.—L. A. C.

Bast fibre plants; Retting ——. P. Krais and K. Biltz. G.P. 332,097, 24.8.19.

THE addition of a small proportion of bicarbonates as well as chalk or other insoluble carbonate to the liquor accelerates the retting process, improves the quality of the fibre, and diminishes the formation of products with a repulsive odour.—L. A. C.

Flax; Process for retting ——. P. Krais. G.P. 332,514, 26.3.20.

THE raw flax is steeped in water or an alkaline solution and is stored moist in the dark at a moderate temperature to promote the formation of fungi, such as species of *Aspergillus*, and retting bacteria, such as *Plectridium pectinovorum*. After 3 to 4 days the retting is complete, and the material is dried at 80° C. or above to kill the fungi and bacteria.—L. A. C.

Peat wool; Production of chemically pure, curly —— *from peaty cotton-grass.* O. Linker. G.P. 332,169, 26.10.18.

THE raw fibrous material, after preliminary treatment for ½ hr. at 50° C. in a 0·5% solution of an alkali, or sulphuric, hydrochloric, or hydrofluoric acid, or other suitable solvent, is rinsed and allowed to ferment for at least 4 hrs. in wooden vessels containing 1 kg. of malt or diastase per 1 cub. m. of water, or 0·5% acid solution, at 50°—60° C., or 11 kg. of yeast per 1 cub. m. of water at 30°—40° C. The fibres are then boiled for at least ½ hr. in an alkaline or acid solution, and are subsequently rinsed with cold water and bleached.—L. A. C.

Fibrous plants; Process for the simultaneous production of textile fibres and paper pulp from ——. Nessel-Anbau-Ges.m.b.H. G.P. 332,170, 16.8.19. Addn. to 328,596 (J., 1921, 211 A).

THE hydrocarbons or halogen derivatives of hydrocarbons employed in the process as described in the chief patent are of the same sp. gr. as the aqueous solution, and thus readily remain in suspension in the same. A sodium hydroxide solution of 5°—8° B. (sp. gr. 1·037—1·060) is recommended, in which case the material is treated for 4½ to 5 hrs. under 8 atm. pressure.—L. A. C.

Waterproofing and sizing composition; Adhesive ——. A. E. Craver. U.S.P. 1,373,412, 5.4.21. Appl., 8.6.20.

THE composition contains a protein, a suitable aqueous solvent, and a substance capable of liberating formaldehyde.—A. J. H.

Impregnating agents [*for fabrics, wood, leather, etc.*]. Farbenfabr. vorm. F. Bayer und Co. G.P. 302,531, 9.2.17.

HALOGEN derivatives of benzene homologues or of coal-tar hydrocarbons containing side-chains, are condensed with tar oils or their constituents (anthracene, naphthalene, benzene, etc.) or derivatives thereof. The oily or resinous products are very suitable for impregnating fabrics, paper yarn, wood, leather, etc., as they adhere firmly to the material, are scarcely soluble in water, and possess preservative properties.—J. H. L.

Impregnating agents; Removal of —— *from fabrics.* G. Bonwitt. G.P. 331,285, 18.7.18.

THE fabrics are extracted, in a suitable apparatus, with solvents of high b.p., such as ethyl lactate, acetylene tetrachloride, or furfural, or with mixtures of such solvents with others of low b.p., *e.g.*, ethyl lactate and formate, acetylene tetrachloride and acetone, cyclohexanone and ethyl acetate, or furfural and ether, or with solvents containing substances which lower the viscosity of the material undergoing extraction; alcohol, for example, lowers the viscosity of solutions of cellulose esters. —J. H. L.

Wood or other substances containing cellulose; Treatment of —— *for the purpose of obtaining cellulose and artificial resin, asphalt, lac, and the like.* C. Claessen. E.P. 160,482, 17.10.19.

CELLULOSIC materials, such as wood, straw, grass, etc., are heated for a few hours at about 100° C. and under reduced pressure with phenol or other phenolic substances either in concentrated form or diluted with water, alcohols, benzol, or aliphatic hydrocarbons; 0·01% of hydrochloric acid (on weight of phenol) is added as a catalyst. The snow-white cellulose pulp produced is removed, part of the phenol is recovered by distillation, and lac or resin is obtained from the liquid residues by precipitation or distillation.—A. J. H.

Cellulose compounds; Manufacture of ——. Deutsche Celluloid Fabr. G.P. 332,203, 10.1.18.

MERCERISED cellulose is treated with chloroacetic acid, or its homologues, in the presence of alkali hydroxides. The alkali salts produced swell in hot or cold water, and finally dissolve to form clear, viscous solutions which on evaporation yield films of a material resembling glue or gelatin and inflammable with difficulty. The free cellulose-acetic acid is a white fibrous substance, insoluble in water, but soluble in alkaline solutions; with lead, copper, or aluminium oxides in the presence of water it forms insoluble salts. The alkali salts of cellulose-acetic acid and cellulose-propionic acid may be used as substitutes for gelatin.—L. A. C.

Paper, pasteboard, and the like; Process for sizing ——. W. Merckens. E.P. 147,006, 6.7.20. Conv., 7.12.15.

ANIMAL or vegetable size (10% on the weight of the fibre) may be directly worked up with half-stuff in the hollander if it be added in a gelatinous form and melts in the subsequent drying process. If necessary, formalin, chrome alum, or other hardening agent is added to the size.—A. J. H.

Paper-making machinery [; *Means for washing the woollen wet felts of* ——]. C. Walmsley and Co., Ltd., and J. Law. E.P. 160,861, 13.9.19.

Drying coated or enamelled paper, waterproofed cloth, and such like; Apparatus for ——. C. F. Howden. E.P. 160,940, 31.12.19.

Fruit and vegetable refuse. G.P. 331,005. *See* XIX A.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

[*Printing.*] *Oxidation by steaming a mixture of a chlorate and an aldehyde-bisulphite compound.* A. Pellizza. Sealed Note 1469, 6.5.04. Bull. Soc. Ind. Mulhouse, 1920, 86, 640—641. Report by A. Lipp. *Ibid.*, 641.

THE reduction of a chlorate by an alkali bisulphite occurs in the cold with too great violence to be applied in printing, but when acetone-bisulphite or

formaldehyde-bisulphite is used, the chlorate is only reduced at about 100° C. and the reaction may be regulated by the presence of small quantities of certain salts. For example, by printing a mixture of a chlorate, acetone-bisulphite, and the salt of an aromatic amine, followed by steaming for several minutes, Turkey Red, chrome mordants, etc. are discharged and Aniline Black is developed. The fibre is not attacked more than is the case when the ordinary mixture of ferrocyanide and chlorate is used. Lipp confirms these claims and agrees that the mixture can be used as an oxidising agent for the development of Aniline Black and as an oxidising discharge. In the case of white discharges, the white is not as clear as that obtained by the use of chlorate, ferrocyanide, and tartaric acid.—F. M. R.

Discharges; Coloured —— on azo-grounds with sulphoxylate-formaldehyde and basic dyes. Justin-Mueller. Sealed Note 1931, 15.12.09. Bull. Soc. Ind. Mulhouse, 1920, **86**, 636—637. Report by C. Sunder. *Ibid.*, 637—639.

The preparation of the fabric with potassium ferrocyanide (J., 1908, 320) complicates the process, as drying is necessary. In order to simplify the process and render it analogous to the usual antimony tannate method, it is modified by the omission of the preliminary preparation, and after steaming the fabric is passed through a potassium ferrocyanide bath. When New Methylene Blue N is used, fuller and brighter discharges are obtained with the modified zinc-ferrocyanide process than is the case with antimony tannate. Sunder reports that the process is worthy of attention in view of the brightness of the shade and the possibility it affords of producing rose-coloured discharges with Rhodamine.—F. M. R.

Patents.

Dyeing and waterproofing [fabrics]; Process for ——. A. O. Tate. U.S.P. 1,374,122, 5.4.21. Appl., 20.4.20.

Fabric is padded with the usual Aniline-Black liquor, aged, impregnated with sodium palmitate and an aluminium salt, and then subjected to an electric current while passing between electrodes, one of which is of aluminium.—A. J. H.

Dyeing fur, hair and the like. Chem. Fabr. Griesheim-Elektron. G.P. 334,012, 15.12.16.

Soft leathers and hair may be dyed shades fast to light by means of the mineral acid salts of amino- and imino-compounds and oxidising agents. The dissociation of the mineral acid is diminished by the addition of neutral salts. By the addition of copper sulphate, a bichromate, sodium perchlorate, and hydrochloric acid to aniline hydrochloride dissolved in a 10% sodium chloride solution, a grey shade fast to light is obtained. Under similar conditions, monobenzylaniline hydrochloride gives a bluish-grey; monobenzyl-2.6.-toluylenediamine hydrochloride gives a bright yellowish-grey, and mono-β-naphthyl-2.6.-toluylenediamine hydrochloride gives a bright fawn shade.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrous acid; Decomposition of ——. [Detection of nitric acid in presence of nitrous acid.] E. Oliveri-Mandalà. Gazz. Chim. Ital., 1921, **51**, I., 138—140.

Hydrazoic acid and nitrous acid react quantitatively according to the equation, $HNO_2+HN_3=H_2O+N_2O+N_2$, no trace of nitric acid being formed. This reaction serves for the detection of nitric acid in presence of nitrous acid, other methods for such detection yielding uncertain results owing to the formation of appreciable traces of nitric acid by partial decomposition of the nitrous acid. The test is carried out as follows:—Either a few c.c. of dilute hydrazoic acid solution or a little of its sodium salt is added to the solution containing nitrous and nitric acids, this being first acidified with acetic acid when the nitrous acid is present as salt. The liquid is boiled to expel, so far as possible, the excess of hydrazoic acid, a portion of the liquid being then tested with an acetic acid solution of naphthylamine and sulphanilic acid to ascertain if all the nitrous acid has been destroyed, and the remainder examined for nitric acid.—T. H. P.

Reduction by metals in acid solutions. I. Reduction of acid ferric sulphate solutions by zinc and magnesium. S. Sugden. Chem. Soc. Trans., 1921, **119**, 233—238.

Quantitative determination of the "percentage reduction" (that is, the percentage of that theoretically possible if no hydrogen were evolved) of acid ferric sulphate solutions, containing varying concentrations of ferric oxide and of sulphuric acid, by means of zinc and magnesium establishes the fact that with both metals increase in the concentration of ferric salt is accompanied by an increase in the percentage reduction, and also the further addition of sulphuric acid to a nearly neutral solution causes a decrease in the percentage reduction. Whilst, however, with magnesium this latter decrease continues progressively as the acid concentration increases, with zinc a minimum is reached, after which the percentage reduction increases rapidly and a new type of reaction apparently sets in, the zinc becoming dull grey in colour, and dissolving much more slowly with a scarcely perceptible evolution of gas. This peculiar behaviour of zinc is most marked with the solutions containing the higher concentrations of ferric oxide.—G. F. M.

Fluorine; Preparation of —— from molten potassium bifluoride. F. Meyer and W. Sandow. Ber., 1921, **54**, 759—766.

The method is a development of that proposed by Argo and others (J., 1919, 413 A). A cylinder of Acheson graphite, which acts as crucible and cathode, is closely surrounded by an electrically-heated copper cylinder. The anode, also of Acheson graphite, is made wider at the lower than at the upper end, and is provided with six vertical grooves to increase the amount of surface exposed. The diaphragm consists of a copper cylinder to the lower end of which four conical copper rings are successively attached and, finally, a reversed ring fastened to a horizontal piece of copper foil. Potassium bifluoride, which gives a thin, clear melt at 240° C., is used as electrolyte, this having proved superior to mixtures of the bifluoride with sodium fluoride or bifluoride, lead or strontium fluorides in point of fluidity and loss of hydrogen fluoride. The crucible is slowly heated to a temperature not exceeding 250° C. and, since the molten salt obstinately retains traces of water, the electrolysis is started with a small current which is continued till the water is completely decomposed, after which the electrolysis proper is commenced. The evolved fluorine is contaminated with hydrogen fluoride, which can be removed by passage over granular sodium fluoride, and, initially, with ozone, which disappears after $\frac{1}{2}$—$\frac{3}{4}$ hr. The electrodes are but little attacked, and the gas does not contain more than 0·2% of carbon tetrafluoride. The current yield is more than 75% of that theoretically possible. (*Cf.* J.C.S., June.)—H. W.

Phosphorus; Oxidation and luminescence of ——. H. B. Weiser and A. Garrison. J. Phys. Chem., 1921, **25**, 61—81.

The reaction between phosphorus and oxygen pro-

bably takes place in the vapour phase, and hence the velocity of reaction, V, may be expressed by the equation $V = kC_p^x . C_o^y$. Since C_p will be constant in presence of solid phosphorus, the velocity should be proportional to some power of the oxygen concentration $V = k_1 C_o^y$. This, however, is not the case below 25° C., and above a certain partial pressure of the oxygen, owing to the formation of a film of oxide on the phosphorus. If the oxygen pressure is great enough, the reaction takes place near the surface of the phosphorus, which will be coated with a film of oxide. By decreasing the partial pressure of the oxygen, this film is destroyed. The same effect may be obtained by increasing the rate of evaporation of the phosphorus. The pressure (boundary pressure) above which a protecting film prevents the oxidation and the vaporisation of the phosphorus is not constant. The intermittent luminescence in the narrow critical region between the boundary pressure and the glow pressure is probably due to the periodical break-down and re-formation of this film.—J. C. K.

Sodium sulphantimonate. Langhans. *See* XXIII.

PATENTS.

[Lead] oxides; Method of converting metallic lead into ——. J. A. Thibault. E.P. 137,288, 29.12.19. Conv., 30.12.18.

GRANULATED lead is heated to 250° C. for 6 hrs. in a closed rotating drum with compressed air at 60 lb. per sq. in. pressure and a small quantity of water vapour, whereby it is converted into litharge of a yellow-ochre colour and of an extra fine texture. Red lead may be produced in the same apparatus by increasing the temperature to 425° C. as soon as all of the lead has been converted into litharge, and continuing the heating for a further period of 4 hrs. The product is a bright red impalpable powder containing over 30% of lead peroxide.—A. R. P.

Electrolysing vat [for making chlorine]. H. Loeb. U.S.P. 1,372,176, 22.3.21. Appl., 10.1.19.

AN electrolysing vat for making chlorine consists of a vessel of glazed pottery surrounded by a wooden casing, the intervening space being packed with asphalt.—J. S. G. T.

Calcium carbonate; Manufacture of ——. L. Roon, Assr. to The Equitable Trust Co. U.S.P. 1,372,193, 22.3.21. Appl., 26.4.19.

MILK of lime is atomised, and the resulting mist allowed to react with carbon dioxide.—C. I.

Calcium carbonate; Manufacture of ——. J. Faldner. G.P. 334,014, 26.11.19.

QUICKLIME is dissolved in a solution of an ammonium salt and impurities are removed by precipitation and filtration. The liquid is then saturated with carbon dioxide under pressure to precipitate calcium carbonate and regenerate the original ammonium salt for use again in the process. —A. R. P.

Aluminium chloride; Production of ——. E. C. Baum and De W. O. Jones, Assrs. to Armour Fertilizer Works. U.S.P. 1,372,332, 22.3.21. Appl., 24.3.20.

ALUMINIUM nitride is subjected to the action of chlorine.—C. I.

Arsenic trioxide; Process of purifying ——. C. P. Linville, Assr. to American Smelting and Refining Co. U.S.P. 1,372,443, 22.3.21. Appl., 21.7.16. Renewed 18.12.19.

COLOURING matter due to selenium is removed by mixing with a reagent capable of forming a non-volatile selenide at a comparatively low temperature and separating the arsenious oxide by sublimation. —C. I.

Zinc oxide; Manufacture of ——. W. L. Coursen, Assr. to The New Jersey Zinc Co. U.S.P. 1,372,486, 22.3.21. Appl., 28.6.20.

IN the production of zinc oxide by the retort volatilisation process, a substantial quantity of molten zinc is maintained in the retort during the whole of the operation, volatilisation losses being made good by the addition of solid zinc to the contents of the retort from time to time.—A. R. P.

[Zinc] oxide; Manufacture of French ——. J. A. Singmaster, Assr. to The New Jersey Zinc Co. U.S.P. 1,372,462, 22.3.21. Appl., 31.3.20.

THE contents of the retorts in which the zinc is volatilised are kept nearly constant by the addition from time to time of molten zinc.—A. R. P.

Bichloride of mercury; Manufacture of ——. C. Schantz. U.S.P. 1,373,357, 29.3.21. Appl., 6.12.20.

MERCURY is passed through an atmosphere of chlorine into a bath of a liquid which does not readily absorb chlorine.—A. R. P.

Fixation of gases [atmospheric nitrogen]; Process for the electric ——. G. T. Southgate. U.S.P. 1,373,639, 5.4.21. Appl., 22.11.20.

STREAMS of gas or gases are passed through porous electrodes between which an electric arc is established.—J. S. G. T.

Calcium cyanamide; Production of —— *from carbide and nitrogen.* A.-G. für Stickstoffdünger. G.P. 299,142, 15.10.15.

CALCIUM carbide and calcium chloride or fluoride are ground together as finely as possible and the mixture, in layers 40—100 cm. deep, is exposed to nitrogen at a lower temperature than has been necessary hitherto, *e.g.*, 650°—700° C., when calcium chloride is used and 700°—750° C. when fluoride is used.—J. H. L.

Calcium cyanamide; Process and furnace for the production of high-grade crude ——. Bayerische Stickstoff-Werke A.-G. G.P. 326,613, 15.3.18.

A NUMBER of small charges are arranged together in a furnace and brought to the ignition point simultaneously. The nitrogen gas necessary for the reaction is brought into the furnace through channels in the wall. Other spaces in the wall are filled with powdered or granular insulating material.—J. H. J.

Gases; Treatment of —— *for removal of hydrogen sulphide.* Badische Anilin- u. Soda-Fabrik. G.P. (A) 299,163, 2.7.16, and (B) 331,322, 22.10.16.

(A) GASES are freed from hydrogen sulphide by treating them with a solution of a compound of iron and oxygen in presence of an alkali, the reduced iron compound being subsequently regenerated by means of air or oxygen. In the case of gases containing little or no carbon dioxide, admission of carbon dioxide, which may be introduced in the form of an alkali carbonate, assists the re-oxidation of the iron compound. A suitable gas-washing solution is prepared by treating 300 kg. of potassium carbonate in 600 l. water with 90 kg. of oxalic acid and 135 kg. of 40% ferric chloride solution, and diluting the product to 1 cub. m. (B) The washing solution may contain oxalic acid together with tartaric acid, and a suitable mixture consists of 200 kg. of potassium carbonate, 20 kg. of crude acid potassium tartrate, 10 kg. of oxalic acid, and 90 kg. of 40% ferric chloride solution, diluted to 1 cub. m.—W. J. W.

Alkali cyanide solutions; Decomposition of ——. W. Salge und Co., Techn. Ges. m. b. H. G.P. 332,297, 9.4.20.

The alkali cyanide is decomposed, and the hydrocyanic acid is removed by passing a current of carbon dioxide into the solution, which contains at least 50% of alkali carbonate. Hydrocyanic acid is distilled without decomposition when carbon dioxide is passed into an alkali cyanide solution containing 50—60% of alkali carbonate at 90° C. —C. A. C.

Calcium hydride; Process for making ——. K. Kaiser. G.P. 333,305, 11.2.20.

Hydrogen is passed over calcium chloride at 600°—700° C. until no further evolution of hydrogen chloride takes place. The residue of pure calcium hydride may be utilised for the hydrogenation of liquid fats and crude petroleum, or for the conversion of acetaldehyde into alcohol as well as for the production of ammonia from the air.—A. R. P.

Ammonia soda; Manufacture of ——. J. Delmar. G.P. 333,748, 19.11.16.

The lime required for the regeneration of ammonia from the ammonium chloride liquors is transformed into calcium cyanamide before being used in the process, whereby further quantities of ammonia are developed as well as a certain amount of carbon dioxide, which is utilised in the first stage of the ammonia soda process. Any excess of ammonia over that required in the latter process may be converted into a suitable salt. 1000 kg. of calcium cyanamide yields 800 kg. of sodium carbonate.—A. R. P.

Sulphur; Process and apparatus for burning —— in easily combustible substances, e.g., spent oxide. Chemische Industrie A.-G. G.P. 333,818, 25.3.15.

The material is charged into a multiple-hearth furnace, underneath the top hearth, through a special charging apparatus, the lower opening of which is kept closed by building up the charge around it. This apparatus is provided with an arrangement to prevent the material sintering and sticking in the neck of the charging cone.—A. R. P.

Potassium salts containing kieserite; Process for utilising the sulphur content of crude ——. J. Kiermayer, and Hannoversche Kaliwerke A.-G. G.P. 333,963, 12.11.19. Addn. to 310,072 (J., 1920, 406 A).

The operation of heating the fused salts with wood charcoal is carried out while passing a current of steam through the mass. Instead of charcoal, liquid or solid hydrocarbons may be used in the process. —A. R. P.

Carbon; Production of pure ——. F. C. Dyche-Teague. E.P. 160,561, 23.12.19.

Coke is converted into carbon monoxide by interaction in a gas-fired retort with carbon dioxide produced in a subsequent stage of the process. The carbon monoxide is decomposed into carbon and carbon dioxide by the catalytic action of finely divided iron or ferric oxide in a separate air-cooled chamber after filtration through firebrick. The carbon deposit and catalyst are blown out of the chamber and separated by a magnetic field or by gravitation.—C. I.

Hydroxides; Manufacture of metal ——. M. Buchner. E.P. 16,597, 24.11.15.

See U.S.P. 1,337,192 of 1920; J., 1920, 488 A.

Oxidation of hydrogen sulphide. G.P. 331,287. *See* IIA.

Hydrating lime. E.P. 160,556. *See* IX.

VIII.—GLASS; CERAMICS.

Glass; Heat absorption in ——. A. Q. Tool and C. G. Eichlin. J. Opt. Soc. Amer., 1920, **4**, 340—363. Chem. Zentr., 1921, **92**, II., 698—699.

On heating glass of constant heat conductivity through a certain well-defined temperature interval some change takes place in the structure of the glass, accompanied by an absorption of heat. An apparatus is described for measuring this heat absorption by comparing the temperatures of a powdered sample of the glass and a sample of clay under the same conditions of heating. The temperature at which the absorption commences varies from 460° to 610° C., and that at which it attains its maximum is 30°—40° C. higher, according to the kind of glass tested. The maximum in the case of quartz is at 580° C. It is shown that on annealing glass not only must the tension be equalised in all parts, but the structure should be made homogeneous; further, annealed glass may undergo a slow transformation into the stable crystalline phase at ordinary temperatures, which gives rise to volume changes, and consequently renders such glass unsuitable for thermometers. —A. R. P.

Refractory materials; Behaviour of —— under load at high temperature. K. Endell. Stahl u. Eisen, 1921, **41**, 6—9.

The behaviour of small cylinders, 50 mm. long and 50 mm. diam., when heated to various temperatures under a pressure of 1—8 kg. per sq. cm. was investigated. The test-pieces were heated in an electric resistance furnace, the pressure—usually 1 kg. per sq. cm.—being applied by a weighted lever through specially hard electrode carbons. The temperature of the test-pieces was measured by a Holborn-Kurlbaum optical pyrometer. The test-pieces were heated so that the maximum temperature was attained in about 4½ hrs, but the results were not appreciably different when only half this time was required. According to their behaviour when heated under a pressure of 1 kg. per sq. cm., refractory materials may be divided into four groups:—(1) Fireclay bricks with a refractoriness of about cone 33 (1730° C.) began to soften at 1300° C., a 50 mm. cylinder being reduced to 30 mm. in a test lasting 4½ hrs., in which the maximum temperature reached was 1500° C. Bricks containing very plastic clay softened at 1150° C. The deformation was uniform, the sides of the cylinder bulging as its height was diminished. (2) Magnesite bricks with a refractoriness above 2000° C. began to soften at 1500° C. on account of the binding agent. A 50-mm. cylinder was reduced to 10 mm. in height in a test lasting 4¾ hrs., the maximum temperature attained being 1650° C. The hot cylinders were feebly plastic and broke at the sides under compression. (3) Silica bricks with a refractoriness of cone 35 (1750° C.) did not soften below 1650° C., but broke in pieces in 4½ hrs. at a maximum temperature of 1680° C. The actual deformation was small. (4) Carbon bricks with a refractoriness above 2000° C. did not soften under pressure, and apart from a slight loss in volume (about 4%), due to some of the carbon burning away, the cylinders were not affected in a test of 5 hrs., in which a temperature of 1720° C. was reached.—A. B. S.

Patents.

Glass and vitreous materials; Manufacture of ——. A. A. Kelly and B. D. Jones. E.P. 160,495, 20.11.19.

In mixtures for making glass and vitreous materials sodium pentaborate is substituted for borax or boric acid, the necessary adjustment of the alkali content being made in any suitable manner. A more homo-

geneous product is secured with an absence of striæ and air bubbles.—H. S. H.

[Glass] annealing furnace or leer. W. O. Amsler. E.P. 160,710, 12.7.20.

A FURNACE has its annealing chamber heated by the hot products of combustion circulated through a number of passages from combustion chambers placed over the top of the muffle. A heating zone is created in which the temperature is maintained above the critical temperature of the articles to be annealed, and a cooling zone which has a predetermined uniform temperature gradient. The articles pass through the muffle from the high temperature zone through the region of decreasing temperature.—H. S. H.

Opaque glazes, enamels, and glasses; Production of white ——. H. Sachse. G.P. 331,682, 20.7.18.

WHITE opaque glasses, enamels, and glazes are made by means of natural compounds of zirconium, tin, and beryllium in combination with fluorine compounds, such as alkali fluorides or fluosilicates, fluorspar, and either natural or artificial cryolite, in sufficient quantity to prevent the production of colour by the impurities in the other ingredients. The large proportion of fluorine compounds ensures good covering power, ready fusibility, high gloss, and great resistance to chemicals and heat.
—A. B. S.

Plastic masses; Manufacture of —— and new industrial products obtained therefrom. L. Gauthier. E.P. 145,514, 22.6.20. Conv., 18.4.19. Addn. to 128,905 (J., 1920, 450 A).

A PLASTIC mass which is capable of being run whilst hot, for the manufacture of hollow bodies, which are unbreakable and capable of being washed (such as vases, dolls' heads, etc.), is prepared by incorporating about 60% of talc with about 30% of gelatin and about 10% of hide glue. The hide glue is melted in a water bath, and the gelatin caused to swell by soaking in water, before being used in the mixture, which is then melted and cooled to form a paste. Slices are cut from the paste, melted in a water bath, and the fluid mass run into a mould and allowed to cool until the desired thickness is attained before pouring out the excess paste. After drying, the hollow body is polished, washed in a solution of Castille soap, and finally treated in a solution of alum and 10% formol.
—H. S. H.

Plastic masses; Process for the production of —— from matter non-plastic by nature, as refractory oxides etc. E. Podszus. G.P. 326,841, 13.7.13.

DURING the grinding process a colloidal solution is produced within the mass either by the known methods of colloid chemistry or by chemical action. For example, at least two non-plastic materials of different basic properties, as alumina and silicic acid, are brought into the most intimate contact with one another by grinding together for a long time in presence of a dispersion medium. The proportions of the two substances are so chosen that sufficient quantities of a colloidal solution are formed to enable the mass to be cast.—J. H. J.

Refractory material. E. D. Frohman. U.S.P. 1,372,016, 22.3.21. Appl., 8.12.19.

A REFRACTORY material comprises a mixture of finely-divided dry fireclay, silicious material, and a vegetable compound capable of forming a binder when mixed with water.—H. H.

Refractory brick. C. W. Berry, Assignor to Laclede-Christy Clay Products Co. U.S.P. 1,373,854, 5.4.21. Appl., 4.4.18.

THE process consists in mixing raw magnesite and bauxite with water, calcining the mixture at a temperature sufficient to expel moisture and gas, re-grinding the product, mixing it with water, forming it into bricks and burning them to produce a hard refractory material.—A. B. S.

Tunnel-kiln. G. E. Norman. U.S.P. 1,372,773, 29.3.21. Appl., 17.2.20.

THE walls and crown of a tunnel-kiln of the customary shape are provided, throughout their full length, with longitudinal air-passages leading into an "exhaust air directing compartment."
—A. B. S.

Tunnel furnace with reversible regenerative heating. H. Koppers. G.P. 331,703, 14.9.18.

THE furnace is designed for heating refractory materials or iron and steel billets with maximum thermal efficiency, by exposure to the highest temperature just before leaving the furnace. The preheated gas and air are brought together at this point and burn while moving counter to the goods in the furnace. Two parallel tunnels are employed.
—H. J. H.

Ceramic materials: Grouped direct-fired furnaces for ——. H. Herda. G.P. 328,389, 23.4.19. Addn. to 324,977 (J., 1920, 821 A).

THE waste gas from a fired furnace and the hot air from a cooling furnace are conducted through flues beneath the furnaces, and are mixed and conducted into the firing duct of the furnace which is to be heated next and into the latter furnace itself. By this means any chamber not in use in the group may be fired as a separate furnace, whether for annealing, melting, or glazing, without interfering with the working of others.—J. H. L.

Ceramic mass of great strength; Production of an easily fusible porcellanous ——. H. Becker, H. Fehringer, and H. Johnke. G.P. 332,578, 21.9.18.

A READILY fusible porcellanous ceramic mass of great strength is made by adding to an alkali-lime glass batch a quantity of fluorspar at least equal to the quantity of silica. The sand may be partly replaced by silicate rock, ashes, or slags. The high fluorspar content makes the fused mass very mobile and prevents the material from being sensitive to sudden changes in temperature, so that large articles do not need prolonged annealing. The ware is opaque.—A. B. S.

Heat treatment of articles [glass bulbs]; Method of —— and apparatus therefor. Corning Glass Works, Assees. of J. Bailey. E.P. 140,374, 17.1.20. Conv., 17.3.19.

Glass; Manufacture [drawing] of ——. F. J. Brougham. From Virginia Plate Glass Corp. E.P. 141,737, 15.4.20.

IX.—BUILDING MATERIALS.

PATENTS.

Refractory and insulating products; Manufacture of ——. G. L. Dimitri and J. E. Delaunay. E.P. 142,513, 1.5.20. Conv., 16.7.18.

HARD, refractory, and insulating products are made by compressing a mixture of hard powdered materials (particularly magnesium silicate and multiple silicates) in a press box from which the air is exhausted. A steel plate or washer slightly smaller than the internal diameter of the press-box is placed on the powdered material, and the press-box is evacuated through an aperture in the air-tight cover whilst the material is being compressed by a rising plunger. When the steel plate is

pressed against the aperture the compression is complete. The pressed pieces are subsequently burned, and are said to be exceptionally hard. —A. B. S.

Porous material [for building and insulation]; Manufacture of ——. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Industri-Hypotekbank. E.P. 143,500, 6.5.20. Conv., 16.5.19.

A MATERIAL of uniform porosity, suitable for building and insulation purposes, is made by blowing air or steam into molten slag, stirring vigorously so as to convert the slag into a foam, cooling the foam rapidly by passing it between water-cooled rollers until it has a temperature at which its porosity remains constant and the mass remains plastic, compressing the mass into the desired shape in moulds, and then cooling it further by gas or air under pressure.—A. B. S.

Oil-proof concrete bodies and method of making same. J. Marcusson. E.P. 145,673, 30.6.20. Conv., 1.7.18.

HOLLOW bodies made from concrete, cement, mortar, etc., are coated with an artificial resin obtained by acting with formaldehyde on phenols or other cyclic compounds. After exposure to the air for a certain time the coating is rendered insoluble, and in this state permanently resists the action of mineral or fatty oils.—H. S. H.

Lime; Apparatus for the hydration of —— and for similar purposes. E. R. Sutcliffe. E.P. 160,556, 22.12.19.

THREE or more cylinders are arranged one above the other with their axes parallel. A shaft carrying vanes is mounted axially within each cylinder, and on rotation causes the material to be hydrated to move slowly along the cylinders. The material is fed into one end of the top cylinder and passes successively through the cylinders. Water is sprayed into the first cylinder, and the others are provided with steam jackets. The product is delivered completely hydrated and in a dried condition.—H. S. H.

Roads; Manufacture of compositions for covering —— and for like purposes. M. Monnoyer and H. T. E. Kirkpatrick. E.P. 161,061, 17.3.20.

A COMPOSITION for covering roads similar to that mentioned in E.P. 4349 of 1914 (F.P. 466,878; J., 1914, 965) is made by incorporating 0·6—1% of fibrous material, such as sawdust, impregnated with tar and bitumen, with a concrete mixture containing 2000—2250 kg. of solid matter.—A. B. S.

Cement; Manufacture of slow-setting ——. F. Ferrari, Assr. to Bombini Parodi-Delfino. U.S.P. 1,372,015, 22.3.21. Appl., 23.8.20.

A RAW mixture of the ordinary type used for Portland cement but having a ratio of Fe_2O_3 to Al_2O_3 between 1 and 1·563 is converted into slag to prepare a slow-setting cement free from the binary calcium compounds of alumina or iron generally used. —H. H.

Wood-impregnating retorts; Condenser and separator for ——. J. H. Dunstan and R. A. Davis. U.S.P. 1,374,069, 5.4.21. Appl., 13.10.19.

IN order to create rapidly a high vacuum in a wood-impregnating retort the latter is connected with a barometric condenser. A pipe leads from the condenser into the side of a barometric separator, and another pipe connects the top of the separator with a vacuum pump. A discharge pipe leads downwards from the bottom of the separator and has its lower end submerged in liquid in a hot well, whereby the separator is able to discharge constantly whilst the vacuum is maintained.—A. B. S.

Building material; Process for the production of —— into which nails can be driven. A. Hambloch. G.P. 326,963, 23.5.18.

A MIXTURE of coarse-grained volcanic sand, tufa, or pumice with a calcareous and fine-grained silicious cement, is shaken to obtain the highest possible density. The moulded articles are hardened with steam under pressure.—J. H. J.

Lump plaster; Manufacture of ——. G. Polysius. G.P. 330,065, 12.9.19.

RAW gypsum is heated in the annular space between two inclined, concentric cylinders which are heated both externally and internally.—A. B. S.

Shipbuilding material; Production of ——. S. Rosenstein. G.P. 331,674, 23.1.19.

A LIGHT material for shipbuilding etc. is made of a pulverised mixture of "1 pt. of cement, 10—25% of lime, and 20—35% of a white silicious and acid-resisting magnesium silicate of the talc group," which after being mixed with porous materials is allowed to stand and finally is mixed with sand or other aggregate and water. The product is so elastic that it can be used to produce richer mixtures than usual without risk of cracking, and it has an extraordinary toughness and a great resistance to blows.—A. B. S.

Slag wool; Production of waterproof articles from ——. H. Brunck. G.P. 331,675, 9.9.19.

SLAG wool is converted into "flocks," the adventitious grains separated by a current of air, and the short fibres and sand grains removed by a sieve. The long fibres aggregate to balls, which are either mixed with a fusible waterproofing material and moulded hot or are placed in a perforated drum and coated by immersion in molten pitch, asphalt, or a resinous mixture, and afterwards shaped in moulds under light pressure.—A. B. S.

Light porous bricks; Process for hardening ——. C. H. Schol. G.P. 332,294, 21.6.18.

LIGHT porous bricks are first exposed to air and are afterwards hardened by exposure to steam under high or low pressure. The preliminary aeration prevents ill effects otherwise produced on exposing such bricks to steam.—A. B. S.

Mortar material; Production of —— from dolomite in a rotary tube furnace. F. M. Meyer. G.P. 332,583, 6.8.12.

THE dolomite is burned for so long and at such a high temperature that the magnesium carbonate is wholly and the calcium carbonate about half converted into oxide.

Lime-sand bricks; Production of —— by means of raw chalk or quarry waste and clay. H. Servange. G.P. 332,631, 25.6.14.

LIME-SAND bricks are hardened in brick kilns at 530° C. in a current of steam and carbon dioxide, the latter being advantageous in the hardening of monocalcium hydrosilicate. The fired bricks harden still further on exposure to air.—A. B. S.

Artificial stone resembling asphalt; Production of ——. A. Flexer. G.P. 332,634, 5.11.18.

IN the manufacture of resin acids for soap making from wood tar by oxidation, a pitch is obtained as a by-product. Artificial stone, resembling asphalt, of great resistance and strength, is made by washing, purifying, and drying this pitch and then mixing it, in the molten condition, with 4—5 times its volume of silica, sand, or other aggregate, and allowing the mixture to cool in sheets or moulds. —A. B. S.

Cement mix; Preparation of —— prior to burning. G. Polysius. G.P. 332,705, 4.12.19.

Hot cement clinker (preferably from a rotary kiln) is mixed with raw cement mix or cement slurry, and later is separated therefrom by means of sieves. This enables the heat in the clinker to be used in preheating the raw material, and the usual cooling drums are rendered unnecessary.—A. B. S.

Bricks from ashes and slaked lime; Production of ——. G. de Bruyn. G.P. 332,755, 14.6.19.

Bricks are made of a mixture of lime, ashes, plastic clay, and water, which is moulded like concrete. The bricks "ring" when struck, are waterproof, and show little "scum." The strength of the bricks and the facility with which nails may be driven into them may be varied by the addition of porous materials such as sawdust, pumice, etc. —A. B. S.

Impregnating agents. G.P. 302,531. *See* V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Malleable iron; Influence of manganese on the mechanical properties of ——. E. Leuenberger. Stahl u. Eisen, 1921, **41**, 285—287.

A higher content than 0·4% Mn is permissible in malleable cast iron, the tensile strength of which increases with the manganese content. Up to about 1% manganese has no influence on the elongation; with higher percentages the elongation diminishes. The tensile strength decreases with the period of annealing while the elongation increases. The longer the time of annealing, the higher may the manganese content be without unfavourably affecting the elongation.—T. H. Bu.

Fluorspar; Addition of —— to Martin [open-hearth steel] furnaces. S. Schleicher. Stahl u. Eisen, 1921, **41**, 357—361.

If fluorspar is added to a Martin slag, it will only be decomposed up to a certain limit, lying between 2 and 2·5% of calcium fluoride. The fluorspar addition at first drives off silicic acid from the slag. This silicic acid is, however, continually renewed from the lining of the furnace. Fluorspar has also a desulphurising action, the sulphur being driven off and the renovated slag taking up more sulphur from the bath.—T. H. Bu.

Electric steel arc furnaces; Regulation of —— using movable electrodes. W. G. Mylius. Trans. Amer. Electrochem. Soc., 1921, 213—225. [Advance copy.]

The different types of automatic electrode regulators are described, including a newer type which operates with greater precision and higher speed than earlier forms. The electrode is moved at high speed until the current per phase is within 15%, on either side, of its normal value, at which point the continuously running stage is replaced by a slower vibrating motion.—C. A. K.

Steel and iron; Gasometric determination of carbon in ——. H. Burkardt. Chem.-Zeit., 1921, **45**, 342.

In adapting Strohlein's apparatus (*cf.* J., 1916, 1085) to the gasometric determination of carbon in steel, the author prefers to use a furnace fitted with carborundum supports, to dispense with the condenser, and to use ordinary wash-bottles for the oxygen in place of those supplied with the apparatus.—W. P. S.

Iron and steel; Influence of copper on the physical properties of ——. E. A. and L. T. Richardson. Chem. and Met. Eng., 1921, **24**, 565—567. (*Cf.* J., 1920, 752 A.)

The addition of even small amounts of copper to iron causes brittleness in forging, but this effect is produced only within a certain range of temperature, above or below which the alloy can be successfully forged. This interval during which "red-shortness" occurs increases with the percentage of copper in the alloy; thus iron containing 4·65% Cu can be forged only at a very low temperature. The phenomenon is probably due to an intergranular film of copper or of one of its alloys or compounds. By the addition of manganese or chromium brittleness is overcome, but the amount added must be proportional to the percentage of copper in the alloy; 0·32% of manganese added to an alloy containing 0·48% Cu removed brittleness, whilst the same amount added to an alloy with 0·92% Cu proved insufficient. The smaller liability of steel to brittleness is explained by its manganese content. The cold-working properties, such as filing, grinding, chiselling, and bending, of iron low in carbon, are not impaired by the presence of copper up to 5%. Manganese makes iron harder, and if the amount exceeds 2% the resulting alloy is too brittle and hard for working; the same proportion of chromium causes hardness and toughness but not brittleness.—W. J. W.

Iron and steel; Anomalies encountered in a study of immersion tests of ——. A. S. Cushman and G. W. Coggeshall. Trans. Amer. Electrochem. Soc., 1921, 249—267. [Advance copy.]

A large number of tests by the immersion of plates in different corroding solutions tend to show that copper-bearing iron is less resistant to corrosion than iron free from copper. After immersion in dilute (5%) mercuric chloride solution steels containing copper were amalgamated with mercury while metal substantially free from copper retained its characteristic grey surface. It is inferred that copper passes into solution with the iron ions, is plated back, and forms a mirror surface with reduced mercury. The passivity of iron in solutions of an alkali bichromate is partially or wholly destroyed in the presence of a copper salt, and it was found that 4—6 times more chromic acid per unit volume is required to prevent corrosion of a copper-bearing steel than is needed to protect iron free from copper. Galvanised sheets immersed in a 10 or 20% solution of aluminium sulphate corrode rapidly, hydrogen being liberated and the zinc coating stripped off. The reaction speed is then reduced greatly if the metal is pure iron, but with copper steels the reaction continues until the iron is dissolved entirely. The system usually turns to a hydroxide gel. A copper steel lost 5 oz. per sq. ft. in a 30-hr. test in boiling aluminium sulphate solution as compared with 2·5 oz. loss for a commercial pure iron. Results from acid tests are not definite, as such tests are sensitive to many electrochemical variables. Dilute sulphuric acid acted rather more vigorously on low copper steel (0·038% Cu) than on steel containing 0·20—0·25% Cu. The order of corrosion was reversed in hydrochloric acid.—C. A. K.

Iron and steel; Corrosion of ——. J. A. Aupperle and D. M. Strickland. Trans. Amer. Electrochem. Soc., 1921, 167—177. [Advance copy.]

The resistance to corrosion of varying grades of pickled iron and steel was determined by suspending plates (6×6 in.) in a solution containing 0·7% of sulphuric acid, 1·98% of ferrous sulphate, and 0·15% of ferric sulphate. The corroding solution was circulated and aerated continuously and was maintained at constant acidity. The loss in weight

in 60 days was as follows:—Pure open-hearth iron 0·622 oz. per sq. ft., copper open-hearth steel (0·257% Cu) 0·75, open-hearth steel 0·779, copper Bessemer steel (0·224% Cu) 2·060, copper acid open-hearth steel (0·209% Cu) 3·263. Metallic copper in contact with various kinds of iron and steel had little effect upon the corrosion of any of the metals with the exception of copper-bearing steel, which was attacked in areas surrounding the contact copper.—C. A. K.

Corrosion of iron by acids; Effect of copper and silver salts on ——. O. P. Watts and H. C. Knapp. Trans. Amer. Electrochem. Soc., 1921, 135—140. [Advance copy.]

Corrosion of iron by sulphuric acid is increased in the presence of copper or silver salts in solution. In $N/1 H_2SO_4$ containing 2·5 g. Cu per l., corrosion due to voltaic action on copper steel (about 0·25% Cu) was nearly four times the direct corrosion by the acid, and in acid solution containing 0·1 g. Cu per l. the ratio of voltaic to direct corrosion was 0·85. Loss by voltaic corrosion of mild steel was of the same order, but the ratio (0·01) appears low owing to the great loss by direct acid corrosion. Figures obtained in tests in which silver salts were added to $N/1$ sulphuric acid indicate less action by a large quantity of silver (2·5 g. per l.) than by either of the lesser quantities (0·1 and 0·01 g. Ag per l.). This is due to the formation of a deposit of spongy silver which retards diffusion of the acid to the steel. In $N/50$ sulphuric acid voltaic action on copper steels and Armco iron appears to be 1—3 times the amount of corrosion due to the acid alone, but wide differences were observed in duplicate experiments. The serious effect of voltaic action is shown by the destruction of a monel metal yacht in which the steel parts in contact with monel metal were corroded away in three months.—C. A. K.

Tin and zinc; Recrystallisation of ——. *Recrystallisation of cold-worked metals.* G. Masing. Int. Zeits. Metallog., 1920, 12, 457—493. Chem. Zentr., 1921, 92, II., 700—701.

The surface tension theory of the recrystallisation of worked metals not only presents theoretical difficulties but also does not explain all the observed facts, *e.g.*, the formation of nuclei, the growth of small crystals at the expense of their larger neighbours, and the failure of unworked metal to recrystallise. Czochralski's stratification theory (Int. Zeits. Metallog., 1916, 8, 1) satisfactorily explains these phenomena but at the same time it gives rise to a new series of problems, such as the nature, stability, and inner structure of a stratified crystal. The recrystallisation of cold-rolled tin begins with the formation of primary grains, the size of which depends on the recrystallisation temperature, and which, after at time, commence to unite, but more slowly than they form. The formation of nuclei cannot be observed, the nuclei of the primary grains being already present in the rolled tin. The size of the grains depends, according to Czochralski's theory, on the amount of rolling that the metal has undergone as well as on the recrystallisation temperature. If a worked piece of tin is subjected to a smaller secondary deformation of a different kind to the first (*e.g.* shearing after rolling, or rolling after hammering) a rapid formation of specially large crystals takes place as the result of two different stratifications. It only ensues if the metal has originally been subjected to a stronger primary deformation and is caused by the rapid grain-growth and by the formation of nuclei, which becomes quicker with rising temperature and with increase of secondary deformation, but tends to be reduced by the effect of the preceding primary deformation. The size of the secondary crystals is in inverse proportion to the number of nuclei formed and the resulting metal is not changed immediately to an even granular structure but exhibits a series of recrystallisation steps with different but characteristic remains of stratification in the grains. Cold-rolled zinc shows a secondary formation of nuclei at 150° C. without being subjected to a secondary deformation; after this, however, recrystallisation commences at 70° C. as the metal is then in a specially unstable condition, which on continued working may again be changed to the normal state, so that the ordinary primary recrystallisation sets in.—A. R. P.

Aluminium utensils; Blackening of ——. J. Czochralski. Z. Metallk., 1920, 12, 430—443. Chem. Zentr., 1921, 92, II., 599.

Blackening occurs readily in aluminium utensils in which water is kept warm. It is due to the deposition of a precipitate containing iron, silicon, and sulphur in greater proportion than the metal itself. No blackening is produced normally by aqueous solutions of iron salts; the blackening which occurs when aluminium is treated with a concentrated solution of ferric chloride in strong hydrochloric and is an etching effect. Blackening occurs when tap water is boiled in an aluminium vessel, and the effect reaches a maximum when all carbonic acid is expelled (20 mins.). The presence of free acids is inhibitory and the phenomenon is connected with the alkalinity of the water. The absence of blackening in domestic practice may be due to the alternations of acid and alkaline conditions in cooking operations. The process is electrolytic and takes place at the eutectic Al—$FeAl_3$, precipitation occurring on the aluminium. It is dependent on the degree of alkalinity and the most pronounced effect was caused by lime water. Synthetic tap water free from iron and spring water behaved like ordinary tap water, while rain water and distilled water produced no effect.—H. J. H.

Nickel; Ductile electrolytic ——. C. P. Madsen. Trans. Amer. Electrochem. Soc., 1921, 269—276. [Advance copy.]

The most satisfactory electrolyte for the production of thick uniform deposits of nickel was found to be nickel sulphate solution containing a small amount of alkali sulphate, a little boric acid and some nickel chloride. Cold-rolled malleable nickel anodes of the composition 95·3% Ni, 2·13% Fe, 0·25% Cu, 0·33% Mn, 0·30% C, and 0·23% Si, gave the best results in this electrolyte when the area of the anode was 1·77 times that of the cathode, the current density 72 amps. per sq. ft. of anode, and the temperature of the bath 55° C. If the cathodes were periodically lifted out of the bath, exposed to the air for a short time, and again immersed in the bath within a certain limiting time, the resulting nickel had a very great ductility, tensile strength, and hardness compared with ordinary nickel. The tensile strength of the deposited metal was about 72,000 lb. per sq. in.; after drawing down to wire of 0·002 in. diam. the tensile strength had increased to 250,000 lb., while the hardness increased from 130 to 150. The metal contained 99·7% Ni, 0·01% Fe, and 0·02% Cu. A tendency of the deposit to form pits was overcome by altering the composition of the anode.—A. R .P.

Nickel deposition; Use of fluorides in solutions for ——. W. Blum. Trans. Amer. Electrochem Soc., 1921, 227—247. [Advance copy.]

The use of fluorides in conjunction with boric acid in nickel plating baths produces nickel deposits that have a finer texture and a higher tensile strength and hardness than those produced in chloride solutions, but the deposit usually contains more iron and copper. The following two solutions

are recommended as electrolytes: 255 g. of nickel sulphate, 12 g. of nickel carbonate, 8 g. of 50% hydrofluoric acid, and 31 g. of boric acid dissolved in water and made up to a litre; or 281 g. of nickel sulphate, 8·4 g. of sodium fluoride, and 31 g. of boric acid dissolved in water and made up to 1 litre. Adherent deposits for electroplating are obtained by using a current density of 3—4 amps. per sq. dm., while 1·5 to 2 amps. is sufficient for electrotyping. Methods for the analysis of the baths are discussed. —A. R. P.

Chrome-nickel heating wires; Structure of ——. M. von Schwarz. Z. Metallk., 1921, **13**, 125—127.

SATISFACTORY chrome-nickel wires for electrical heating purposes show a fine-grained structure both before and after prolonged use. The used wires show superficial oxidation and some slag inclusions below the surface. Inferior wires which have appeared on the market within the last few years have a similar fine-grained structure before use, but after use the structure becomes coarser and the wires become very brittle. Good wires contain about 86·5% Ni, 10·1% Cr, and only small quantities of iron, whilst a sample of the new inferior wire contained 52·7% Ni, 10·7% Cr, and 32·3% Fe. The inferiority of the latter is due to the replacement of so large a proportion of the nickel by iron.—E. H. R.

Smelting; Theory of ——. *II.* W. Guertler. *Equilibria between pairs of metals and sulphur. I. The system copper-lead-sulphur.* K. L. Meissner. Metall und Erz, 1921, **18**, 145—152.

GUERTLER (Metall u. Erz, 1920, **17**, 192) has shown that when sulphur is added to a mixture of copper and lead, Cu_2S is first formed, then PbS, and finally CuS, and these relations were illustrated by means of a triangular diagram. In this diagram the ternary system is divided into three partial systems, Pb—Cu—Cu_2S, Pb—Cu_2S—PbS, and Cu_2S—PbS—S. Various mixtures corresponding with points in each of these partial systems have now been examined thermally and microscopically. Each pair of constituents in the first ternary system shows incomplete miscibility, and consequently an area of incomplete miscibility would be expected in the ternary system, with three separate phases. Actually only two layers are formed, the upper consisting essentially of Cu_2S, the lower being an emulsion of lead and copper, in which the lead shows a pronounced tendency to liquate downwards. Through this emulsion formation, copper and lead can be made practically completely miscible by addition of 1—1·5% of sulphur. Addition of lead to the Cu—Cu_2S system extends the miscibility gap. In the partial system Pb—Cu_2S—PbS, a miscibility gap extends almost up to the Cu_2S—PbS line. In the absence of free lead, *i.e.*, on the Cu_2S—PbS line, only eutectic mixtures are formed. In the third ternary partial system, Cu_2S—PbS—S, it was expected that the line PbS—CuS would correspond with a quasi-binary series of mixtures, but, owing to the decomposition of CuS into Cu_2S and sulphur on melting, equilibrium was established between PbS, Cu_2S, and an apparently ternary crystalline phase. —E. H. R.

Alloys; Use of shear tests for judging the mechanical properties of ——. R. Krulla. Z. Metallk., 1921, **13**, 137—139.

A SHEAR test is made on a test-piece having a cross-section of 0·5 sq. cm., and from the area of the shear diagram, measured by means of a planimeter, the shearing work is determined in kg.-m. per sq. cm. This quantity, divided by the Brinell hardness (previously determined on the same test-piece) gives a number Q, which serves to indicate the relation of strength to hardness in the alloy. Thus for copper, Q=4·96, for the brass Cu 69·5%, Zn 30·5%, Q=8·34, and for Cu 49%, Zn 51%, Q=0·85. —E. H. R.

Mercury; Physical properties of ——. A. Schulze. Z. Metallk., 1921, **13**, 105—113, 139—148.

A REVIEW of the literature dealing with the determination of the magnitudes of the physical properties of mercury, grouped under the headings mechanical, thermal, electrical and magnetic, and optical.—E. H. R.

Reduction by metals in acid solutions. Sugden. *See* VII.

PATENTS.

Pig iron from iron and steel scrap; Production of high-grade ——. F. Rottmann. G.P. 332,208, 13.3.19.

CLEAN iron and steel scrap is melted with a pure slag made from quartz, lime, or clay shale. Iron low in phosphorus may thus be obtained.—H. J. H.

Iron and steel baths; Preventing the re-phosphorising of —— *during deoxidation and carburising.* Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G. G.P. 333,749, 19.4.16.

THE bath of molten iron or steel is treated with calcium carbide, at or towards the end of the deoxidation or carburising operations. The method is especially applicable to the Thomas process where the slag is high in phosphorus, and to the manufacture of hard steel.—A. R. P.

Ferro-chromium; Process for producing low-carbon ——. F. Krupp A.-G. E.P. 145,710, 26.6.20. Conv., 3.10.16. Addn. to 145,709 (J., 1921, 307 A).

CRUDE ferro-chromium is treated in an acid-lined converter until a low carbon content is obtained. Basic material, *e.g.* lime, is then added to the charge, whereby silicon is oxidised and the loss of chromium is reduced.—C. A. K.

Ferrotitanium; Process for producing low-carbon ——. H. C. Sicard, Assr. to U.S. Ferro Alloys Corp. U.S.P. (A) 1,374,035 and (B) 1,374,036, 5.4.21. Appl., 18.8.19.

(A) COMMERCIAL ferrotitanium is mixed with an excess of titanic oxide and heated in an electric furnace so as to decompose carbides of titanium and iron and form a protective titanium oxide slag. (B) A double carbide of titanium and iron is treated in a molten state with aluminium. Carbon separates as graphite and is skimmed off, and the underlying metal is reheated and cast.—C. A. K.

Ferro-zirconium; Production of low-carbon —— *Process for producing zirconium steel.* H. C. Sicard. U.S.P. (A) 1,374,037 and (B) 1,374,038, 5.4.21. Appl., 23.7.20.

(A) A HIGH-CARBON ferro-zirconium alloy is decarbonised by means of titanic oxide. (B) An alloy of zirconium and silicon is added to molten steel. —B. M. V.

Roasting and sintering ores and the like. R. L. Lloyd. E.P. 160,477, 4.9.19.

AN improved machine for carrying out mechanically the operations of charging, igniting, sintering, and discharging in the Dwight-Lloyd process, as described in E.P. 25,985 of 1907 (J., 1908, 1025). —B. M. V.

Solid substances capable of reaction with a gaseous reagent; Process of treating ——. [*Roasting sulphide ores.*] E. C. R. Marks. From Ore Roasting Development Co. E.P. 161,103, 6.7.20.

A MULTIPLE-HEARTH mechanical roaster is provided with by-pass ore passages, so that a portion of th

ore can fall direct from the second or any subsequent hearth to some lower hearth. One or more by-passes may be provided, so that after initial heating on the top hearths the ore will divide into two or more streams which will subsequently be united into one before final discharge from the apparatus. Air, or other gas, may also be admitted at several different places, preferably near the outlets of the by-passes, and some of the products of combustion may be readmitted.—B. M. V.

Electrode for use in electric welding or fusion deposition of metals. Quasi Arc Co., Ltd., and A. P. Strohmenger. E.P. 160,957, 7.1.20.

An electrode wire is wrapped spirally with a yarn of blue asbestos. The asbestos fibres are pulped with a solution of sodium silicate and rolled into a thin sheet, which is cut into strips and spun into a spirally twisted yarn.—C. A. K.

Slag; Process of cleaning converter ——. H. H. Stout, Assr. to Phelps Dodge Corp. U.S.P. 1,372,047, 22.3.21. Appl., 3.2.19.

For the removal of copper from converter slag the specific gravity and silica content of the latter are adjusted to those of the reverberatory slag before the two are mixed.—D. F. T.

Electrolytic recovery of metals from solutions; Electrode for ——. U. C. Tainton. U.S.P. 1,373,273, 29.3.21. Appl., 4.11.19.

A permeable electrode suitable for the electrolytic deposition of metals from solutions is composed of a paper sheet in which is incorporated a comminuted conducting material.—J. S. G. T.

Electrolytic process [for treating copper ores]. W. E. Greenawalt. U.S.P. 1,373,557, 5.4.21. Appl., 22.3.20.

Copper ores are treated with an acid solution, and copper is deposited electrolytically from the resulting solution containing also salts of elements of variable valency (iron etc.). These latter salts are reduced from the higher to the lower valency by agitating the electrolyte in the presence of sulphur dioxide and finely divided charcoal.—J. S. G. T.

Furnace; Revolving ——. L. P. Basset. U.S.P. 1,372,392, 22.3.21. Appl., 12.9.19.

An inclined rotating cylindrical furnace has its diameter increased at the lower end to form a reaction chamber adapted to form a pocket for molten metal.—B. M. V.

Furnace [; Open-hearth ——]. N. F. Egler, Assr. to Blair Engineering Co. U.S.P. 1,372,613, 22.3.21. Appl., 1.3.19.

Means are provided whereby air may be passed from the regenerators to combined air and fuel ports at each end of the furnace, which are narrow compared with the hearth, and also through other channels direct to the interior of the furnace; the latter channels may be shut off if desired.—B. M. V.

Melting furnace [; Electric brass ——]. T. F. Baily and F. T. Cope, Assrs. to The Electric Furnace Co. U.S.P. 1,373,787, 5.4.21. Appl., 16.2.20.

An electric furnace for melting brass, in which the heat is produced by the resistance of an annular trough of coarsely powdered carbon, is fitted with a condenser connected with the upper part of the heating chamber and provided with an inclined neck communicating with the heating chamber near the hearth of the furnace.—A. R. P.

Blast furnaces; Process for operating —— with the use of lignite. F. Weeren. G.P. 331,596, 11.1.12.

A large proportion of the coke or charcoal in the charge is replaced by lignite briquettes, and the ore and limestone are added in small lumps or as a powder. In the upper part of the furnace the bituminous constituents of the lignite reduce the iron oxide in the ore, and the carbonised briquettes break up into small pieces which serve for smelting and carburising the iron.—L. A. C.

Copper; Process of case hardening ——. A. S. Gundersen. U.S.P. 1,372,423, 22.3.21. Appl., 1.12.15.

The surface of the copper is exposed to zinc at a temperature between the melting points of copper and zinc.—B. M. V.

[Aluminium] ores; Process for the reduction of ——. C. G. Collins, Assr. to C. A. Stevens. U.S.P. 1,372,483, 23.3.21. Appl., 26.3.20.

The finely ground ore is mixed with a carbonaceous material and sodium chloride, and the mixture is heated out of contact with the air.—A. R. P.

Aluminium; Process for coating metallic objects with ——. Metallhütte Baer und Co. Kommanditges. G.P. 330,917, 11.4.19.

For the coating of objects made of metals harder than aluminium a mixture of hard sand with powdered aluminium, in which the particles of the latter are larger than those of the former, is projected against the surface of the object by means of air under a pressure of 1—4 atm.—J. H. L.

Aluminium; Electrolytic manufacture of ——. Allgem. Elektrizitäts-Ges. G.P. 332,669, 1.3.18.

Alternating current is passed through the bath for the purpose of heating, without any heating resistances, whilst at the same time electrolysis is effected by a direct current. The danger of the solidification of the bath is thus avoided in case of defects at the generator of the direct current, and losses in the transformation of the generally available alternating current into direct current are minimised. —C. A. C.

Precious metals [gold and silver]; Method of recovering —— from solutions. R. H. McKee. U.S.P. 1,372,971, 29.3.21. Appl., 13.5.20.

Solutions containing gold and silver are brought into contact with carbon which has previously been subjected to an alkaline treatment at a suitable temperature and subsequently leached before use. —A. R. P.

Silver; Method of extracting —— [from ores or residues]. P. R. Middleton, Assr. to J. C. Lalor. U.S.P. 1,372,973, 29.3.21. Appl., 11.5.20.

Ores or residues containing metallic silver are subjected to treatment to convert the silver into sulphide, which is then chlorinated.—A. R. P.

Zinc and cadmium; Process for separating and recovering —— by acid treatment. J. Leibu. G.P. 329,172, 9.6.17. Addn. to 322,142 (J., 1920, 788 A).

The residues containing cadmium are heated before treatment with acid. The formation of malodorous substances is thereby avoided.—J. H. L.

Metals; Process for recovering —— from ores. H. Dahlem. G.P. 332,445, 4.2.20. Addn. to 330,290 (J., 1921, 265 A).

In the process described in the chief patent the furnace is so designed that air or gas for reduction can be blown independently into the furnace through all the tuyères, both at the sides and at the bottom of the furnace.—L. A. C.

Metallic coatings; Production of —— by spraying atomised liquid metals. P. Künzler. G.P. 330,916, 20.9.13.

The metal is melted for the spraying operation by

conducting it, in a comminuted but not pulverulent form, through a duct which is strongly heated from without. By this means metals which are difficult to melt and readily oxidisable, such as aluminium and copper, can be used in the spray coating process.—J. H. L.

Coating articles by spraying with a dispersed liquid material. P. Künzler. G.P. 332,047, 21.10.13. Addn. to 330,916 (*cf. supra*).

The coating material is used in form of pieces of regular shape, especially balls. The method is of special value in the case of easily oxidisable metals, *e.g.*, aluminium, which might solidify and oxidise when fused in large quantities.—C. A. C.

Etching and stamping processes; Plates for ——. Verein. Elektrochem. Fabr. O. Hahn. G.P. 330,948, 21.11.19.

The plates are made of magnesium or magnesium alloys; they are very hard and suitable for etching and engraving.—J. H. L.

Sludge from wet purification of blast-furnace gas; Removal and utilisation of ——. F. Eckert. G.P. 332,628, 30.11.19.

By mixing the sludge with the slag from the blast-furnaces the water content of the sludge is evaporated by the heat of the slag, whilst the dry residue adheres to the granulated slag. The hydraulic properties of the slag are improved by the admixture of the sludge.—C. A. C.

Steel; Manufacture of ——. A. Pacz, Assr. to General Electric Co. U.S.P. 1,373,908, 5.4.21. Appl., 17.8.17.

See E.P. 152,371 of 1918; J., 1920, 787 A.

Alloys. F. Milliken. E.P. 161,104, 6.7.20.

See U.S.P. 1,354,990 of 1920; J., 1920, 754 A.

Welding of different metals to form a composite ingot. A. G. C. Pittevil. U.S.P. 1,374,110, 5.4.21. Appl., 14.10.18.

See E.P. 122,365 of 1918; J., 1919, 183 A.

Blast-furnace gas. E.P. 153,263. *See* IIA.

Tunnel furnace. G.P. 331,703. *See* VIII.

XI.—ELECTRO-CHEMISTRY.

Electric furnaces; Electro-dynamic forces in ——. C. Hering. Trans. Amer. Electrochem. Soc., 1921, 201—211. [Advance copy.]

The author discusses the nature of the mechanical forces which may be directed to cause an increased directional motion of a liquid conductor, *e.g.*, molten metal, in an electric furnace. The "pinch" effect (J., 1909, 1143) is now applied to many furnaces. The author reiterates his view that a component of the electro-dynamic force may act in an axial direction when two currents are inclined to each other. The rising of metal on the outer side of the ring of an induction furnace is explained as due to the "stretching" of the current-carrying bath of metal, and not indirectly as the result of hydraulic forces.—C. A. K.

Patents.

Electric [arc] furnaces. The British Thomson-Houston Co., Ltd., H. C. Hastings, and N. Laycock. E.P. 160,529, 19.12.19.

In electric arc furnaces to which power is supplied from single-phase or two-phase four-wire circuits, and in which there are two arcs in series per phase, one of the arcs being controlled by the arc current and the other by the voltage across the arc as described in E.P. 119,228 (U.S.P. 1,255,613; J., 1918, 213 A) a system of magnetic relays operates to prevent the voltage-controlled electrode from being lowered when the current is abnormally high, and to prevent the current-controlled electrode from being lowered when the arc voltage is abnormally high. Relays are provided whereby one or both of the electrodes per phase may be raised at a higher speed than the normal operating speed during the period when the current in the arcs exceeds a predetermined value.—J. S. G. T.

Storage battery electrode and process of making same. H. C. Hubbell, Assr. to Hubbell-Fuller Battery Co.. U.S.P. (A) 1,373,733 and (B) 1,373,734, 5.4.21. Appl., 9.7.15. Renewed 13.8.20.

(A) A storage battery electrode is made by heating nickel oxide with finely divided cadmium. (B) Precipitated cobaltous hydroxide is converted into oxide by heating it without substantial exposure to air. The oxide is cooled under the same conditions and mixed with a material containing nickel, and the mixture formed into tablets and assembled in a conducting container.—J. S. G. T.

Storage battery plates; Process of making ——. W. H. Grimditch, Assr. to Philadelphia Storage Battery Co. U.S.P. 1,374,076, 5.4.21. Appl., 24.7.20.

Lead oxide containing red lead is mixed in definite proportion with a solution of ammonium sulphate of a definite strength, at a predetermined temperature, such that the mixture has the plasticity required for applying it to the battery grid.

—J. S. G. T.

Lead peroxide-zinc cells or batteries; Process of making —— *capable of being kept.* Ringe und Co. G.P. 333,299, 6.1.18.

Substances such as the hydroxides of calcium, magnesium or barium, are added to the electrolyte or to the positive electrode, or to both, in order to prevent the formation of lead chloride.—A. R. P.

XII.—FATS; OILS; WAXES.

Twitchell reagent; The ——. E. Hoyer. Z. Deuts. Oel- und Fettind., 1921, 41, 113—115. Chem. Zentr., 1921, 92, II., 665—666.

In the Twitchell process, the aromatic sulpho-fatty acid serves to emulsify the fat or oil, whilst the free sulphuric acid present effects the hydrolysis; removal of the sulphuric acid by washing or treatment with normal sodium sulphate, sodium bisulphite, or sodium acetate retards the hydrolysis, as also does the addition of formic, acetic, or sulphurous acid. The Petroff reagent consisting of sulphonic acids obtained as a waste product in the purification of petroleum is considered superior to the Twitchell reagent. The discoloration which occurs during hydrolysis depends on the amount of

sulphuric acid present, so that it is advisable to use as little of this acid and of the reagent as possible; the resulting fatty acids are more susceptible to discoloration than are their parent fats and oils. —D. F. T.

Oil of Gilletiella congolana; Properties and composition of the ——. A. Boulay. Bull. Sci. Pharmacol., 1920, 27, 626—628. Chem. Zentr., 1921, 92, I., 576.

THE seeds of *G. congolana* collected in the neighbourhood of Matadi were at most 45 mm. long, and 25 g. in weight. The oil extracted by petroleum spirit is clear, but deposits crystals in the course of a few days. It has the following characters:—Sp. gr. 0·9159, free oleic acid 0·79%, saponif. value 192·5, iodine value 93·8, Hehner value 90, soluble volatile acids 0·77%, acetyl value 7·0, unsaponifiable matter 1·14%, m.p. of fatty acids 29°; the fatty acids consist of 35% of solid acids (palmitic etc.), and 65% of liquid acids (linolic and oleic acids). —G. F. M.

Fats; Law of probability applied to the formation of —— *from carbohydrates.* E. J. Witzemann. J. Phys. Chem., 1921, 25, 55—60.

IF the relative abundance of occurrence of the various fatty acids is plotted against the number of carbon atoms in the molecule, and the points corresponding to the relative abundance of the various acids are connected, instead of obtaining a smooth curve on both sides of C_{18}, the curve shows prominences at several points, and therefore does not conform with the typical probability curve. But, if the prominences are connected, such a curve is obtained. The numbers of carbon atoms at the prominences are all divisible by six, but C_{18} fatty acids occur considerably more frequently than others; this affords support for Fischer's hypothesis of the formation of fatty acids from sugars. The less frequent occurrence of intermediate acids may be due to their formation from higher and unsaturated acids, or by synthesis from short carbon chains. —J. C. K.

Catalytic activity of platinum; Influence of mercury, sulphur, arsenic, and zinc on the ——. E. B. Maxted. Chem. Soc. Trans., 1921, 119, 225—233. (*Cf.* J., 1921, 89 A.)

THE inhibitive action of mercury, sulphur, arsenic, and zinc on the catalytic activity of platinum when employed for the catalytic hydrogenation of oleic acid under standard conditions was studied by similar means to those previously employed in the case of inhibition by lead (*loc. cit.*), and the existence of a similar linear poisoning law has been established. For the above substances the linear law appears to hold between the limits of zero concentration of inhibitant up to a region in the neighbourhood of total extinction, where a point of inflexion occurs from which the poisoning curve slopes far less steeply towards complete inactivity.—G. F. M.

Hexabromide value of fatty oils; Determination of ——. A. Eibner. Farben-Zeit., 1921, 26, 1314—1315.

THE method of Bailey and Baldsiefen (J., 1921, 51 A) gives lower values than those obtained by the methods of Eibner and Muggenthaler (J., 1913, 242), Wolff (J., 1920, 417 A), and Steele and Washburn (J., 1920, 197 A). The presence of fish oils as adulterants of linseed oil may be detected by testing the solubility of the octobromides in boiling benzol and determination of the melting point of the solute. A further useful method of recognition of fish oils is that of Tsujimoto (J., 1920, 825 A) depending on the separation of clupanodonic acid as the lithium salt.—A. de W.

Partly hydrolysed fats (soap-stock); Analysis of ——. W. Fahrion. Chem. Umschau, 1921, 28, 68—69.

THE aqueous layer from the alkali refining of vegetable oils yields on acidification a product which contains neutral fat in addition to fatty acids, and is largely used in soap manufacture. Errors may occur when the free fatty acid content of the material is calculated from the ratio of the acid value to the saponification value, since the equivalent weight of fatty acid is less than that of its corresponding glyceride by the equivalent weight of the glyceryl radicle. Error is also caused by the small differences existing between neutralisation and saponification values of free fatty acids. In many cases, however, these errors compensate one another sufficiently for all practical purposes. The author recommends the following procedure: A weighed quantity of the soap stock is warmed with alcohol and the acid value determined. A measured amount of alcoholic alkali is then added and the ester value determined in the usual way. The neutral soap is then rendered alkaline, diluted to an alcoholic strength of 50—20%, and the unsaponifiable matter (y) extracted with petroleum-spirit, or ether. The free fatty acid (x) then corresponds to $(100-y) \times$ acid value/saponif. value, and the percentage of neutral fat is obtained from the difference: $100-(x+y)$.—A. de W.

Lard. Drummond and others. *See* XIXA.

PATENTS.

Fats and oils; Process for the removal of fatty acids, resins, bitter and mucilaginous substances from ——. H. Bollmann. U.S.P. 1,371,342, 15.3.21. Appl., 22.6.20.

A CONTINUOUS current of diluted solvent for the impurities is passed upward through a systematic leaching apparatus comprising a number of vessels each containing a body of stationary filling material, whilst a continuous current of the oil to be purified passes through in a downward direction, whereby intimate contact of oil and solvent is produced without violent agitation of the materials, and the quantity of difficultly separable emulsion formed is reduced to a minimum.—A. de W.

[Vegetable] oils; Process of treating [purifying] ——. *Treatment of castor oil.* A. Schwarcman, Assr. to S. Kellogg and Sons, Inc. U.S.P. (A) 1,372,631 and (B) 1,372,632, 22.3.21. Appl., 19.2. and 20.4.20.

(A) VEGETABLE oils are agitated with an amount of strong caustic soda solution corresponding to the content of free fatty acids in the oil, the temperature is raised to about 180° F. (82° C.), and hot water passed, in finely divided form, into and through the mixture. (B) Castor oil is mixed with a limited amount of soda solution of moderate strength to neutralise the free fatty acids, hot water added with thorough agitation, the aqueous layer allowed to settle, the oil washed with hot water, and finally dried.—A. de W.

Fatty acids; Distillation of ——. J. W. Bodman, Assr. to W. Garrigue and Co., Inc. U.S.P. 1,372,477, 22.3.21. Appl., 9.8.19.

To remove their dark colour fatty acids are brought, in the form of spray only, into contact with a gaseous carrier, in a vacuum, under heat conditions suitable for the complete distillation of the acids. The evaporated fatty acids are condensed.—A. de W.

Fatty matter; Extraction of —— from garbage and other fat-containing materials. V. Bredlik and L. C. Whiton, jun. U.S.P. 1,372,479, 22.3.21. Appl., 15.5.19.

In extracting the fatty matter from garbage and other material containing grease or oil by means of a solvent, the material to be extracted is subjected to a preliminary treatment of alternately higher and lower gaseous pressures in the absence of the solvent.—A. de W

Fatty acids and their glycerides; Production of ——. Oelverwertung G.m.b.H. G.P. 330,811, 22.8.12. Addn. to 292,649.

A mixture of nickel oxide with fat or a fatty acid is heated in a current of hydrogen, and the colloidal product is used as a catalyst in the hydrogenation of oils. By this means only a small proportion of the oil need be heated to the high temperature necessary for the colloidal distribution of the catalyst. A hard fat with a setting pt. about 50° C. may thus be prepared from cottonseed oil, and dihydroxystearic glycerol ester from castor oil.
—J. H. L.

Saponaceous compositions; Manufacture of ——. F. G. Chadbourne. E.P. 160,892, 1.12.19.

Fatty acids are melted in a steam-jacketed pan and incorporated in a rotary mixer with 20—50% by weight (on the final product) of a finely divided hydrated aluminium silicate, *e.g.*, china clay, together with colouring matter. The required quantity of alkaline solution is then run in, the mixing operation continued for about 1 hr. at a temperature below boiling-point, steam being admitted through a steam coil, and the mass is concentrated to the desired consistency.—A. de W.

Emulsion and method of producing it. E. M. Johansen, Assr. to The Atlantic Refining Co. U.S.P. 1,373,661, 5.4.21. Appl., 14.12.20.

Mineral oils are emulsified with water in the presence of water-soluble sulphonates, obtained by the acid treatment of mineral oils or products therefrom, to the extent of about 1·5 to 8% of the weight of mineral oil.—L. A. C.

Detergent. Chem. Fabr. vorm Weiler-ter Meer. G.P. 330,355, 24.2.17. Addn. to 327,683 (J., 1921, 186 A).

Instead of pulverulent insoluble substance a mixture of soluble salts is used which gives rise to a fine precipitate when introduced into water, *e.g.*, xylene mixed with magnesium sulphate and sodium carbonate and sulphate, or chlorobenzene mixed with aluminium sulphate and sodium carbonate.
—J. H. L.

Detergent which lathers well; Production of a ——. E. Reinfurth. G.P. 332,649, 1.8.16.

Soluble salts of α- or β-naphthalenemonosulphonic acid, or of both α and β acids, preferably alkali or ammonium salts, are added to a soap during or after the production of the latter, and a filling agent, such as clay, may also be added. As much as 50—70% of the fatty acid may be replaced by the abovementioned acids without any loss of lathering power.—J. H. L.

Detersive and emulsive agents; Manufacture of ——. R. Macpherson and W. E. Heys. U.S.P. 1,373,900, 5.4.21. Appl., 23,5.16.

See E.P. 8478 of 1915; J., 1916, 852.

See also pages (A) 333, *Soap powder* (E.P. 145,048). 339, *Montan wax* (G.P. 334,155). 358, *Moulded article from tung oil* (U.S.P. 1,372,114). 365, *Culinary product. Edible oil* (U.S.P. 1,372,614–5); *Maize meal* (G.P. 328,425).

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Ferric oxide; Anhydrous yellow ——. J. H. Yoe. J. Phys. Chem., 1921, 25, 196—200.

In an extension of Scheetz's work on the stabilisation of the colour of anhydrous yellow ferric oxide (J., 1917, 1270), aqueous solutions of ferrous and aluminium sulphates were precipitated with calcium and barium hydroxides, and the precipitate heated to 1000° C.; a yellow or buff colour persisted in mixtures containing up to about 8% of ferric oxide, but above this amount the colour gradually darkened. Similar results obtained with ferrous and aluminium chlorides indicate that the presence of calcium or barium sulphate in the mixture is not essential for stabilisation, but that alumina alone is sufficient to prevent agglomeration and to maintain the yellow colour of the ferric oxide. This conclusion is confirmed by precipitating both sulphates and chlorides of iron and aluminium with ammonia solution. In regard to calcium and barium sulphates, it is found that if these are present in large excess they act as stabilising agents; thus a product containing 6% of ferric oxide and 94% of barium sulphate is of a light buff colour similar to that obtained in presence of alumina. Attempts to retain the colour in products stabilised with alumina after removal of the latter by sodium hydroxide were unsuccessful, as agglomeration of the ferric oxide with corresponding change of colour to red, occurred in each case.—W. J. W.

Paint films; [The "Paint-Film Gauge," an] instrument for measuring the thickness of wet ——. A. H. Pfund. J. Franklin Inst., 1921, 191, 517—523.

The instrument consists of a plano-convex lens of 25 cm. radius of curvature mounted in a short tube sliding freely in an outer tube. The two tubes are held together by springs, and by applying pressure the inner tube can be forced outwards and the convex surface of the lens brought into contact with *e.g.* a wet paint film. The diameter (D) of the circular spot of wet paint left on the lens when the pressure is released is measured to 0·1 mm., and the thickness (t) of the paint film can then be calculated by the formula: $t = D^2/16R$, where R is the radius of curvature of the lens. Good agreement was shown in practice between results obtained by the instrument and results of actual spreading trials with paints and varnishes. Shrinkage of paint films on drying may be determined by means of the instrument, the thickness of the dry film being measured with a micrometer. The variation in brightness of paint films on drying may be measured by determining the thickness of the film at the point of critical opacity in a wedge-shaped pool of the paint, the thickness at several points at various other distances from the apex of the wedge being also determined. After drying, the change in position towards or away from the wedge apex of the point of critical opacity is observed and the thickness of the wet paint film formerly overlying this spot is obtained from the previous measurements. It was found that opacity in paints does not vary with shrinkage but increases directly as the brightness.—A. de W.

Ink; Acidity of —— and the influence of bottle glass on ink. C. A. Mitchell. Analyst, 1921, 46, 129—134.

The stability of iron-gall inks depends chiefly on the amount of acid present, and this amount must be kept within definite limits; the acid usually added is hydrochloric acid. Certain inks, consisting essentially of iron gallate solution, do not re-

quire the addition of mineral acid, but it is held generally that these inks lack "body." To determine mineral acid in ink, a portion of the sample is distilled with the addition of sodium acetate until the whole of the liberated acetic acid has passed over into the distillate; the acidity of the latter is then titrated. The total acidity of the ink is determined by boiling 5 c.c. of the sample with 10 c.c. of hydrogen peroxide under a reflux condenser until the colour has been discharged and then titrating the cooled mixture with sodium hydroxide solution, using phenolphthalein as indicator. Logwood inks require to be boiled with alkaline hydrogen peroxide solution in order to destroy the colour; an allowance is made for the amount of alkali added. Results of determinations of acidity of commercial inks are recorded; usually the total acidity is equivalent to 1·6—5·6 c.c. of $N/1$ alkali solution per 10 c.c. of ink, and the mineral acidity to 0·3—2·46 c.c. of $N/10$ alkali solution per 10 c.c. Investigation of certain deteriorated inks showed that the damage had been caused by alkali dissolved from the glass bottles.—W. P. S.

Pine resin; Acid constituents of ——: d- and l-pimaric acids. G. Dupont. Comptes rend., 1921, **172**, 923—925.

By the use of aqueous alcohol as solvent it has been found possible to isolate appreciable quantities of *l*-pimaric acid from the resin of the leaf buds of *Pinus maritima*. This acid is readily isomerised to the dextro-acid under the conditions usually employed for the extraction of pimaric acid from this source.—W. G.

Rosin; Action of trichloroethylene on ——. F. Goldschmidt and G. Weiss. Z. Deuts. Oel- und Fettind., 1921, **41**, 99—100. Chem. Zentr., 1921, **92**, II., 651.

A black deposit in the salting out of soaps prepared from a mixture of equal parts of stearin and rosin which had been extracted with trichloroethylene was traced to the presence of less volatile impurities in this solvent. Rosin dissolved in an unsaturated compound such as turpentine or allyl alcohol yields dark-coloured products when treated with air in the presence of iron.—D. F. T.

Furfural; Some synthetic resins from ——. G. H. Mains and M. Phillips. Chem. and Met. Eng., 1921, **24**, 661—663.

The condensation of furfural, which can now be produced very cheaply on a large scale from maize cobs, with various amines and ketones has been studied and the optimum conditions for the production of fusible resins suitable for use in varnishes are given. One part of furfural heated with an equal weight of aniline for 1 hr. at 200° C. or with twice its weight of α-naphthylamine for 3 hrs. at 200° C. gives a black resin which is hard and brittle at 25° C. In some cases addition of hydrochloric acid to the reaction mixture is necessary; thus one pt. of furfural condenses with 2 pts. of *o*-toluidine or with 1 pt. of crude xylidine only in the presence of 0·2 pt. of strong hydrochloric acid at 150° C. to yield a hard black resin. Condensation products with acetone or methyl ethyl ketone are obtained on heating suitable mixtures in the presence of 50% sodium hydroxide solution. A black resin is obtained by heating furfural with 25% caustic soda for 1 hr. and treating the solution with hydrochloric acid. All the resins obtained softened between 25° and 100° C., were practically insoluble in water, somewhat soluble in turpentine, readily soluble in benzene, acetone, and alcohol, and very soluble in furfural. Solutions of the resins in benzene, acetone, or furfural give shades on wood ranging from golden brown to black, according to the nature and concentration of the solution.—A. R. P.

Varnishes; Testing of ——. H. Wolff. Farben-Zeit., 1921, **26**, 1186—1187.

Films of the various varnishes under examination dried under similar conditions of time, etc., on both glass plates and tinned iron plates, are hung up in large glass bell-jars filled with a mixture of moist sulphur dioxide and carbon dioxide for a period of from 8 days to 8 weeks. Other tests comprise leading the mixed gases, both at ordinary temperatures and heated by passage through a tube immersed in a boiling water-bath, over the surfaces of the films (locomotive varnish test). Criteria as to the relative resistance of the varnishes can then be obtained by macroscopical and microscopical inspection, rubbing with the finger, etc. —A. de W.

Lead, manganese, and cobalt as driers. W. Flatt. Farben-Zeit., 1921, **26**, 1441.

The relative speed of drying at 10° C. of oils boiled with various driers was found to be as follows: Lead drier (1 pt. Pb in 100 pts. of oil), 20 hrs.; manganese (1 in 400), 20 hrs.; cobalt (1 pt. 1200), 16 hrs. The form in which the base is dissolved in the oil is without influence on the drying power. A boiled oil containing 1% Pb is, however, extraordinarily heavy-bodied, and eventually becomes turbid and deposits "foots" possessing the same siccative power as the soluble part of the lead. The speed of drying at different temperatures of boiled oils varies with the nature of the drier; thus, exposure at 5° C. of the boiled oils referred to above in the order named, results in dry films being obtained in 24, 44, and 36 hrs. respectively. The progress of oxidation is dissimiliar with the three bases; thus with a lead drier the oil showed definite signs of oxidation (thickening etc.) in 12 hrs., with cobalt there were no signs of drying before 18 hrs., whilst with manganese the oil showed no alteration before 20 hrs.' exposure. A mixture of oils boiled with a lead drier and a manganese drier respectively dried in 16 hrs., the component oils when tested separately drying in 20 hrs. and 24 hrs. respectively. In a similar manner a 20-hr. lead-boiled oil mixed with a 16-hr. cobalt-boiled oil dried in 16 hrs. Relatively small amounts of manganese produce considerable acceleration of drying in oils boiled with lead driers. Manganese-boiled oils increase in drying power on ageing to a degree equal to that obtainable by mixing with lead-boiled oils. —A. de W.

Pressure oxidation of phenols. Fischer and Schrader. *See* III.

Patents.

White lead; Apparatus for the manufacture of ——. E. W. Dahl. E.P. 160,395, 2.7.20.

The apparatus consists of two wooden boxes each provided with an endless belt enclosed in a casing. The material, *e.g.*, comminuted lead, acetic or nitric acid, and water is transferred by one belt from the lower portion of one box to the upper portion of the second, where it is discharged and falls over a series of inclined baffle plates and on to the lower portion of the second belt, the operation being repeated continuously and the reacting material continually passing from one box to the other. The belts are carried on wooden rollers mounted on driving shafts. The boxes are provided with charging hoppers and discharging traps, manholes, and means for the inlet and discharge of carbon dioxide, air, and steam.—A. de W.

Drying chambers, more particularly for dye-, varnish-, lacquer-, and enamel-coatings. Standard Lack Werke, G.m.b.H. E.P. 147,562, 8.7.20. Conv., 21.10.13.

A closed drying chamber is provided with two heat-

ing coils on opposite sides, near the bottom, behind baffles, in order to induce an upward circulation of heated air. A cooling coil is set in the middle plane of the drying chamber close below the roofing and is provided with a trough to receive condensed water. A "transferring device" influenced by the humidity of the chamber acts upon a valve either to admit water to the cooling coil, thereby effecting a reduction of humidity in the chamber by causing condensation, or to allow cold water to pass directly to the open trough beneath the coil, thereby increasing the humidity.—A. de W.

Phenolic bodies; Condensation of —— with aldehydic compounds. Vickers, Ltd., The Ioco Proofing Co., Ltd., and W. H. Nuttall. E.P. 160,258, 15.12.19.

PHENOLIC substances and aldehydic compounds or compounds capable of producing formaldehyde are condensed by the aid of a catalyst comprising a salt or salts of hexamethylenetetramine, *e.g.*, the chloride, sulphate, phthalate, and/or a double compound thereof with phenol, pyrogallol, ethyl bromide, potassium antimony tartrate, etc., the proportion of the catalyst being such that the quantity of hexamethylenetetramine does not exceed 2% of the weight of the main ingredients of the composition. The character of the product may be varied by altering the relative proportions of phenolic substance and aldehydic compound and the nature of the catalyst or mixture of catalysts. —A. de W.

Moulded article [from tung oil] and method of making same. L. H. Baekeland, Assr. to General Bakelite Co. U.S.P. 1,372,114, 22.3.21. Appl., 12.1.18. (*Cf.* U.S.P. 1,312,093; J., 1919, 730 A.)

TUNG oil is heated to a relatively high temperature short of that at which solidification occurs, the treated oil mixed with an inert filling material, the mixture moulded, baked, and an insoluble external coating applied.—A. de W.

Resinous composition; Fusible odourless —— and process of making same. W. E. B. Baker and H. Weaver. U.S.P. 1,373,044, 29.3.21. Appl., 23.4.20.

A FUSED resin is caused to react with an oxidising compound adapted to liberate nascent oxygen and destroy the odoriferous constituent originally present in the resin without substantially affecting the properties of the main constituent of the resin. —A. de W.

Fumigant paint. H. A. Gardner. U.S.P. 1,373,499, 5.4.21. Appl., 27.12.20.

A FUMIGANT coating composition contains a chlorinated derivative of benzol. (*Cf.* J., 1921, 187 A.)—A. de W.

Sulphonated resin and method of making same. A. Horwitz. U.S.P. 1,373,886, 5.4.21. Appl., 19.11.18.

A SULPHONATED resin soluble in water is obtained by the treatment of a resin with sulphuric acid. —A. de W.

Resins; Process for bleaching ——. G. Ruth and E. Asser. G.P. 329,186, 21.12.19.

THE resin is dissolved in a solvent, neutralised if necessary, and saturated, preferably warm, with hydrogen sulphide. Iron compounds present as impurities are thus precipitated.—J. H. L.

Glycerides of aliphatic acids; Method for rendering soluble the solidified (polymerised) ——. O. Nagel. G.P. 331,870, 9.3.20.

SUBSEQUENT to or during the polymerisation process, colloids soluble in the desired solvent are added. Polymerised linseed oil after treatment with casein or vegetable gum will give with water or a hydrocarbon solvent a solution or emulsion which can be applied in the same way as paint.—D. F. T.

Resinous condensation products; Production of ——. Akt.-Ges. für Anilin-Fabr. G.P. (A) 332,334, 28.6.18, and (B) 332,391, 9.1.18.

(A) FORMALDEHYDE or substances capable of yielding formaldehyde are made to interact with halogen-substituted derivatives of naphthalene in the presence of acids. From α-chloronaphthalene there are thus obtained clear elastic resins, soluble in benzene, chlorobenzene, fatty oils, or turpentine, and suitable for use in varnishes and for the preservation of leather. (B) Resinous products insoluble in alcohol, but soluble in benzene, turpentine, and linseed oil are obtained by the action of a metal halide on an additive compound of naphthalene with a halogen, or on halogen-substituted derivatives of hydronaphthalenes either alone or mixed with aromatic hydrocarbons. Typical products are those obtained from the action of aluminium chloride on a solution of naphthalene tetrachloride in toluene, of ferric chloride on a mixture of 1-chloronaphthalene tetrachloride with naphthalene, and of antimony pentachloride on a solution of a similar mixture dissolved in tetrachloroethane.—D. F. T.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Amyrin and lupeol in the rubber from Ficus Vogelii. A. J. Ultée. Ber., 1921, 54, 784—785.

SPENCE (J., 1907, 422) has described the isolation of α- and β-albans, m.p. 201°—205° C. and 154° C. respectively, from *Ficus vogelii*. The former is shown to be identical with α-amyrin acetate, m.p. 218° C.; the latter contains lupeol, probably as the acetate. The terms, α- and β-alban, should be deleted from the literature.—H. W.

PATENTS.

Rubber goods and materials; Process for obtaining vulcanised —— containing substances which are adversely affected by certain vulcanising processes. S. J. Peachey and A. Skipsey. E.P. 160,499, 24.11.19.

FILLING materials, such as sawdust, cork dust, leather waste, and wool waste, which are adversely affected by ordinary vulcanisation, also lake pigments, can be used satisfactorily in compounding rubber which is to be vulcanised by the special method described in E.P. 129,826 (J., 1919, 688 A). D. F. T.

Rubber; Process of compounding lubricated sulphur and —— and vulcanising. D. Repony, Assr. to Manhattan Mfg. Co. U.S.P. 1,372,041, 22.3.21. Appl., 24.9.19.

SULPHUR, which has been treated with a lubricant, is introduced into the previously formed mixture of rubber and the other compounding ingredients. —D. F. T.

Caoutchoucs; Pre-treatment of commercial artificial —— which are difficult to work on the rolls owing to insufficient adhesiveness and elasticity. Akkumulatoren-Fabr. A.-G. G.P. 329,171, 3.1.17.

THE material is exposed to a temperature above 100° C., and if necessary washed and kneaded at the same time. The product dried in the usual way exhibits when worked almost the same adhesiveness, elasticity, "nerve," and capacity for filling materials as natural rubber.—J. H. L.

Rubber; Increasing the elasticity of vulcanisates from artificial or natural ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 332,347, 16.1.19.

BEFORE vulcanisation, an aryl or aralkyl ether, *e.g.*, 5% of dibenzyl or dixylyl ether, is added to the rubber.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Gallotannin. XII. M. Nierenstein, C. W. Spiers, and A. Geake. Chem. Soc. Trans., 1921, **119**, 275—286.

FURTHER evidence obtained on the constitution of gallotannin seems to throw doubt on the correctness of the pentadigalloylglucose formula of Fischer and Freudenberg (J., 1912, 503). The formation of ellagic acid from gallotannin occurs in two distinct stages, the first producing a maximum of 60%, and the second giving only traces of ellagic acid, but about 8% of dextrose. Similarly, partially hydrolysed gallotannin gave ellagic acid in two distinct stages, whereas from the pentadigalloylglucose formula simultaneous production of ellagic acid and dextrose would have been expected. Further, the methylated derivative of the above partially hydrolysed gallotannin, and also of gallotannin itself, gave on hydrolysis tetramethylglucose. These results are fundamentally opposed to the pentadigalloylglucose formula, since apparently four hydroxyl groups of the glucose in gallotannin are free unless the methylation with diazomethane had caused a replacement of the acyl groups, which, however, was shown to be excluded by the fact that dextrose, and not tetramethylglucose, was formed by the hydrolysis of the methylation product obtained by the action of diazomethane on a synthetic pentagalloylglucose.—G. F. M.

PATENTS.

Tanning material; Production of a ——. H. Hassler. G.P. 306,341, 9.12.13.

CRYSTALLINE sulphonic acids of unsubstituted tricyclic aromatic hydrocarbons, or the condensation products of aromatic sulphonic acids, may be used either alone, or mixed with other natural agents, for tanning hides. An acid reaction is maintained during the process, and the resulting leather is of a bright appearance. Suitable compounds are anthracenedisulphonic acids, and condensation products of naphthalenesulphonic acid, as well as sulphonic acids of phenanthrene and fluorene.—W. J. W.

Patent leather; Process for hardening ——. J. J. Stöckly. G.P. 331,871, 14.4.18.

HARDENING of the surface of enamelled or patent leather is accelerated by treatment with ethyl alcohol. It is further advantageous to add an alkali to neutralise acidity developed during drying, which exerts a retarding action on the hardening. —W. J. W.

Tanning material; Production of a ——. H. Renner and W. Moeller. G.P. 333,403, 12.12.18. Addn. to 262,333 (J., 1913, 878).

ACID resin or acid tar from the refining of mineral oils is treated with alkali or alkaline-earth sulphides, polysulphides, or hydrosulphides instead of with hydroxides or carbonates as described in the chief patent. If calcium (or barium) sulphide is employed, the precipitate of sulphate formed carries down with it the highly coloured impurities, and the clear liquor obtained after filtration can be used immediately for tanning, yielding a light-coloured leather.—L. A. C.

Catgut; Sterilisation of ——. O. Frey. G.P. 331,169, 13.3.19.

THE intestinal skins are treated with solutions of diaminomethylacridinium chloride (Trypaflavin). They may further be dressed, *e.g.*, with tannin or potassium iodide solution containing iodine. —J. H. L.

Catgut; Preparation of ——. C. Braun. G.P. 332,383, 1.8.18.

BY treatment of the intestines with a solution of chlorine or bromine, previous to or instead of the usual treatment with iodine solution, surface hardening is avoided and the disinfecting solution more easily penetrates into the body of the material. —B. V. S.

Casein; Production of —— in a form suitable for the manufacture of translucent horn-like materials. R. Weiss. G.P. 331,440, 26.10.17.

AFTER separation of albumin from milk, the casein is precipitated with aluminium acetate, and then freed from fat by treatment with a mixture of alcohol and another solvent. Owing to the shrinkage caused by the aluminium acetate precipitation, enough moisture is retained by the casein to permit of its being moulded into a transparent, horny material.—W. J. W.

XVI.—SOILS; FERTILISERS.

Soils; Adsorption phenomena in ——. VI. Determination of adsorbed bases, and their significance for processes which take place in the soil. D. J. Hissink. Versl. Landbouwk. Onderzoek. Rijkslandbouwproefstat., 1920, 144—150. Chem. Zentr., 1921, **92**, II., 594—595. (*Cf.* J., 1919, 918 A.)

BASES occur in the soil in two forms between which there is little interchange, viz., in an adsorbed form, probably as ions, easily replaced by other ions, *e.g.*, by treatment with ammonium salts, and on the other hand in a form soluble in acids. The adsorbed bases form the supply immediately available for plant nutrition. To determine adsorbed lime or magnesia, 25 g. of soil (or 50 g. in the case of humic sandy soil) is treated with 100 c.c. of warm $N/1$ sodium chloride solution and left to stand. On the following day it is filtered and washed with $N/1$ sodium chloride solution until two litre flasks have been filled in turn with the filtrate and washings. The difference between the lime-content of the first and second litres represents the amount of adsorbed lime in the soil, and similarly for magnesia. To determine adsorbed soda and potash 25 g. of soil is treated as above with $N/1$ ammonium chloride solution, and two successive lots of ½ l. each of filtrate are collected, the difference between their contents of potash or soda representing the amount adsorbed in the soil. Average results for a number of clay soils showed 30 mg.-equivalents of calcium ions, 5 of magnesium, 0·8 of potassium, and 2·5 of sodium ions per 100 g. of soil; *i.e.*, of 100 adsorbed cations 79 were calcium, 13 magnesium, 2 potassium, and 6 sodium ions. Importance is attached to the "state of saturation" of a soil, *i.e.*, the ratio of the number of adsorbed cations to the number which the soil is capable of adsorbing, but there is at present no accurate method of determining the latter value. In moist sea climates the soils are

unsaturated and are liable to become "acid." A soil which had been spoiled by flooding with sea water contained per 100 adsorbed cations 56·9 of calcium, 20·2 of magnesium, 3·7 of potassium, and 19·2 of sodium. The flooding had also spoiled the organic matter, by converting calcium humate gels into sodium humate sols.—J. H. L.

Soil; Experiments on chemical and bacteriological changes in ——. F. Münter. Landw. Jahrb., 1920, **55**, 62—138. Chem. Zentr., 1921, **92**, II., 68—69.

MANY experiments were performed upon the influence of saline fertilisers on soil. Monobasic calcium phosphate raised the solubility of silica and lessened the solubility of iron and calcium salts. Neutral and basic calcium salts lessened the solubility of silica. The solubility of tribasic calcium phosphate in ammonium chloride was increased in soils poor in lime and rich in silica, whereas the solubility of calcium carbonate in ammonium chloride was lessened. The solubility of lime in water was increased by the presence of potassium chloride, potassium sulphate, and ammonium sulphate. The solubility of magnesia in water and in dilute hydrochloric acid was increased by acid calcium phosphate. In soils containing much iron and clay, the addition of caustic lime diminished the solubility of phosphoric acid in dilute hydrochloric acid. In aqueous solution phosphoric acid is absorbed by lime, iron, and clay, and then behaves similarly to tribasic calcium phosphate. Whilst almost all added phosphoric acid can be recovered by acid from soils rich in lime, 70% of it is retained by soils poor in lime but rich in iron and clay. With regard to the solubility of phosphates, it was found that although ammonium oxalate and acetate could dissolve many of them, yet the best and quickest solvent was citric acid. The influence of moisture upon the nitrogenous changes was investigated and it was found that the heavier the soil, the higher must its water content be for the same amount of decomposition to take place in the organic nitrogenous substances. The rapidity of the formation of ammonia and nitric acid in presence of little moisture increased as the lightness of the soil increased. In soils with much moisture the highest nitrate content was found in sandy soils, because in heavy soils nitrate was decomposed, as much as 32% being lost in a loam soil compared with 9% in a sandy soil. The presence of zeolites caused a sandy soil to behave like a loam soil with respect to ammonification and nitrification. Actinomycetes in soil were found to obtain their nitrogen supply from inorganic as well as organic sources and their carbon supply from carbohydrates and organic acids. Urea, thiourea, and dicyanodiamide served only as sources of nitrogen. Alkali salts were tolerated up to 5%; larger amounts of the alkaline-earths were rendered harmless owing to conversion into carbonates. These fungi effected ammonification, but nitrification was only slight, and evolution of nitrogen did not occur at all; neither did nitrogen fixation, even in the presence of other organisms.—J. H. J.

Soils; Relation of the calcium content of some Kansas —— *to the soil reaction as determined by the electrometric titration.* C. O. Swanson, W. L. Latshaw, and E. L. Tague. J. Agric. Res., 1921, **20**, 855—868.

THE total calcium and calcium in forms soluble in $N/5$ and $N/1$ hydrochloric acid, present in a number of Kansas soils, and the hydrogen-ion concentration of suspensions of 10 g. of the soil in 100 c.c. of water were determined. In soils with a high calcium content, a larger percentage of the calcium was in forms soluble in the dilute hydrochloric acid than in soils with a low calcium content. As a rule soils with a high calcium content had a higher hydroxyl-ion concentration than those with a low calcium content, but the amount of $N/25$ calcium hydroxide necessary to change a soil from a lower to a higher hydroxyl-ion concentration was dependent rather upon the amount of colloidal clay present than upon the calcium content. The amount of $N/25$ calcium hydroxide required to change the p_H value of acid soils to 7, when calculated in terms of calcium carbonate per acre, compared moderately well with the results from the Hopkins method for determining lime requirements. Subsoils, as a rule, had a higher calcium content than surface soils and required more calcium hydroxide to change their p_H values over a given range.—W. G.

Azotobacter. Kayser. Comptes rend., 1921, **172**, 939—940. (*Cf.* J., 1921, 155 A.)

A FURTHER study of the effect of colour on Azotobacter at different stages of its culture and the influence of temperature in varying the results. At 27° C. the generations from yellow and blue growths gave practically the same results in respect to total nitrogen fixed and nitrogen fixed per gram of mannitol consumed. The utilisation of mannitol became less satisfactory as the time of incubation was extended. It was more satisfactory at 8°—16° C. than at 27° C., although the total nitrogen fixed at the lower temperature was much less.
—W. G.

Arsenic, antimony, and fluorine compounds; Poisonous action of —— *on plant cultures.* A. Wöber. Angew. Botanik, 1920, **2**, 161—178. Chem. Zentr., 1921, **92**, I., 35—36.

AMONG the plants most susceptible to poisons were beans, peas, barley, oats, wheat, maize, and rye. In water cultures 0·01 g. of arsenious oxide per litre had a very poisonous effect, arsenic pentoxide being less poisonous, and at a concentration of 0·1 g. per l. all plants died. Antimony compounds had much lower toxic powers than this. Sodium fluoride had an injurious effect at a strength of 0·1 g. per l. When dusted on soil arsenious oxide had a less poisonous effect than arsenic pentoxide, and antimonious oxide was still less poisonous and was about on a par with sodium fluoride. When sprinkled on green plants, solutions of arsenic acid were more injurious than those of arsenious acid, whereas their sodium salts behaved in a converse manner. Sodium fluoride had a caustic effect in 1% strength.—J. H. J.

PATENTS.

Phosphatic fertiliser; Process for the manufacture of ——. F. J. Tromp. U.S.P. 1,372,051, 22.3.21. Appl., 11.6.19.

FOR the production of phosphates soluble in citric acid, iron phosphate or aluminium phosphate is treated with a mixture of lime and a caustifiable compound of an alkali metal in the presence of water.—D. F. T.

Fertilisers; Manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 333,671, 31.3.18. Addn. to 332,114 (J., 1921, 315 A).

COARSELY crushed superphosphate is mixed directly with ammonium bicarbonate and the mixture ground.—A. R. P.

Seeds; Treatment of ——. Chem. Fabr. L. Meyer. G.P. 327,310, 10.8.19. Addn. to 321,797 (J., 1920, 667 A).

PHENOLS may be used in admixture with mercury or silver salts without injuring the germinating capacity of the seeds.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Clerget method [*of determining sucrose by double polarisation*]; *Application of the —— to dilute solutions.* R. F. Jackson and C. L. Gillis. Int. Sugar J., 1921, **23**, 217—220.

Replying to Browne's criticism (J., 1921, 271 A), it is pointed out that, while the optical rotation of sucrose in the presence of ammonium chloride, sodium chloride, etc. (J., 1920, 634 A) is increased in dilute solution, that of invert sugar, on the other hand, is diminished, the effect of the salt added being compensating (within the limit of error) in the two polarisations. In any case, the effect is small, a value, for example, of 19·17° S. being obtained in the case of 5 g. of sucrose in the presence of 3·392 g. of ammonium chloride per 100 c.c., whereas the value would have been 19·12° if the rotation had been strictly proportional to the concentration. Results of analyses are reproduced showing the average error in the proposed method of neutral polarisation to be only 0·02% in the case of pure solutions of sucrose containing 3—7 g. per 100 c.c.—J. P. O.

Sugars; Iodometric determination of ——. J. L. Baker and H. F. E. Hulton. Biochem. J., 1920, **14**, 754—756.

The method of Willstätter and Schüdel (J., 1918, 556 A) is accurate. The reagents must be added in the order- sugar, iodine, alkali, and the time of oxidation need be only 3—5 mins. (*Cf.* J.C.S., May.)—J. C. D.

Sugar analysis; Iodometric determination of copper and its use in ——. I. Equilibria in the reaction between copper sulphate and potassium iodide. P. A. Shaffer and A. F. Hartmann. J. Biol. Chem., 1921, **45**, 349—364.

The influence of the equilibrium between copper sulphate and potassium iodide on the estimation of sugars has been investigated. For the determination of cupric salts potassium iodide must be added to give a final concentration of about 0·25 *M* (4—5 g. per 100 c.c). For the determination of cuprous salts the final concentration of copper and of iodide should not exceed about 5 millimolar each. A number of the methods in use (Gooch and Heath, J., 1907, 991; Maclean, J. Physiol., 1916, **1**, 168; Biochem. J., 1919, **13**, 135; Scales, J., 1915, 1261) comply with the requirements. (*Cf.* J.C.S., May.) —J. C. D.

Sugar analysis; Iodometric determination of copper and its use in ——. II. Methods for the determination of reducing sugars in blood, urine, milk, and other solutions. P. A. Shaffer and A. F. Hartmann. J. Biol. Chem., 1921, **45**, 365—390.

The principles outlines in a previous paper (*cf. supra*) have been applied to the methods for the estimation of reducing sugars in biological fluids. —J. C. D.

Polysaccharides. II. Constitution of diamylose. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 169—173. (*Cf.* J., 1920, 795 A.)

Acetyl bromide at the ordinary temperature converts α-tetra-amylose (*cf.* Pringsheim and Langhans, J., 1912, 1001) first into acetylated α-diamylose and then into acetobromomaltose, which is obtained in quantitative yield. α-Diamylose is therefore an anhydride of maltose and is the first known anhydride of a disaccharide. (*Cf.* J.C.S., May.) —T. H. P.

Polysaccharides. IV. Degradation of potato starch. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 185—202.

The experiments of Karrer (J., 1920, 795 A) have been completed and extended. Methylation of purified potato starch by means of methyl sulphate and baryta water leads to a methylostarch having the molecular weight in water 990—1026, or, allowing for inorganic matter present, 1200 at most. Aqueous or chloroform solutions of this compound contain colloidal particles, but are rendered optically empty by ultra-filtration; these are, therefore, true crystalloidal solutions, and they may be evaporated to dryness in a vacuum without alteration in the properties of the solute. This methylostarch, $C_6H_8O_3(OCH_3)_2$, is attacked neither by diastase nor by ptyalin; *Bacillus macerans*, which degrades ordinary starch to crystalline dextrins, does not develop in its solutions or cause its depolymerisation. The authors consider that the starch molecule contains not more than six dextrose residues united by chemically normal linkings; the number may, indeed, be less than six, since it is not certain that the limits of depolymerisation are reached by the methylation. (*Cf.* J.C.S., May.)—T. H. P.

Polysaccharides. VI. Constitution of starch and glycogen. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 263—269.

Dry potato starch is attacked by acetyl bromide at the ordinary temperature, with formation of acetobromomaltose in large proportions. As experiments with other polysaccharides have shown that the glucosidic linking is stable towards acetyl bromide, it is assumed that in the starch molecule not more than two dextrose residues are united by normal glucosidic valencies. Starch may also be hydrolysed, with formation of well-defined products, by enzymes, by acid, and by *Bacillus macerans*, and consideration of these reactions indicates that starch is a polymerised maltose anhydride (diamylose). The degree of polymerisation is probably not very high, the high value usually attributed to the molecular weight of starch being presumed, erroneously, from its insolubility. Glycogen also must be regarded as a polymerised diamylose, the degree of polymerisation being different from that of starch.—T. H. P.

Patents.

[*Sugar juices and other*] *liquids or liquors; Process for the purification and separation or filtration of ——. Filtering, decolorising, and purifying processes for liquids and liquors, juices, liquefied bodies, and the like.* J. N. A. Sauer. E.P. (A) 155,609 and (B) 155,611, 20.6.19.

(A) In a systematic process successive portions of the liquid, at progressive stages of purification, are passed in turn through a filter containing highly active, finely divided decolorising carbon. The filter is then recharged with fresh carbon (which may first be mixed with the most advanced liquid portion and transferred to the filter with the latter), and the cycle of operations is repeated, each portion of liquid being advanced one stage at every cycle. Any portion may be passed several times through the filter if necessary. The raw liquid introduced as the last portion in each cycle may have received a preliminary purification, and instead of being merely passed through the filter containing the nearly exhausted carbon it may be mixed with the latter and filtered. (B) In the treatment of liquids with highly active, finely divided decolorising carbon, instead of employing just the amount necessary for one quantity of liquid so that the

carbon is spent thereby, a considerably greater amount is used so that it will serve for several successive quantities of liquid of the same degree of purity or colour. The time required for the treatment of a given quantity of liquid is very much reduced by this means.—J. H. L.

Sugar; Decolorising and purifying ——. D. Grant. E.P. 159,640, 6.12.19.

RAW or incompletely refined sugar is mixed with a suitable proportion (0·5—6%) of dry active decolorising carbon, or kieselguhr, or both. In this form the sugar may be shipped in bulk and transported pneumatically, and it undergoes relatively little bacterial deterioration during storage. The refining of sugar thus treated is more economical in respect of purifying materials and time than in the case of untreated raw sugar.—J. H. L.

Sugar-cane and similar materials; Treatment of ——. F. H. Lindenberg, Assr. to The Jeffrey Manufacturing Co. U.S.P. 1,369,180, 22.2.21. Appl., 13.1.16.

FOR the complete extraction of the juice the cane is thoroughly disintegrated so as to form a homogeneous pulp from which the fibrous matter is afterwards separated. The disintegration of the cane may be carried out in stages.—J. H. L.

Sugar-beets; Process of making a palatable syrup from ——. S. F. Sherwood. U.S.P. 1,370,372, 1.3.21. Appl., 19.5.20.

SUGAR-BEETS are heated in water and the extract, separated from the solid matter, is heated at about 109° C. in an autoclave for 1 hr., in the course of which considerable quantities of steam are blown off at intervals of about 15 mins., whereby objectionable flavouring substances are eliminated. —J. H. L.

Sugar; Manufacture of —— *direct from the juice.* E. Delafond. U.S.P. 1,371,997, 15.3.21. Appl., 24.7.20.

SUGAR juices and syrups are purified by passing them between electrodes, and at the same time keeping them in sufficiently rapid motion to prevent any substantial deposition on the electrodes. —J. H. L.

Sugar; Counter-current apparatus, in particular for the extraction of plant slices containing ——. Maschinen und Werkzeugfabr. A.-G. vorm. A. Paschen. G.P. 331,129, 17.12.19.

IN apparatus with separating chambers for the temporary separation of the liquid from the slices by means of overflow walls, according to G.P. 267,133, 269,925, and 278,067 (*cf.* U.S.P. 1,077,296 and 1,134,152; J., 1913, 1123; 1915, 567), the separating chambers are provided with a wide outlet orifice for the liquid. There is no danger of slices entering through this orifice, owing to the strong counter-current of liquid.—J. H. L.

Sugar for consumption; Production of —— *from massecuites and their drainings.* A. Müller. G.P. 329,890, 17.1.20.

THE boiling of the massecuite is arrested at a higher moisture content than usual, and it is brought to the density necessary for satisfactory centrifuging by adding, either in the vacuum pan or preferably in the cooler, dry or moist sugar, massecuite of low moisture content, or a mixture of grainy sugar and thick syrup or the latter alone. The strongly coloured solutions obtained in boiling out or steaming out the evaporating plant are worked up separately. With careful working, sugars for direct consumption may be obtained even from second products without re-melting. —J. H. L.

Molasses; Process for the desaccharification of ——. A. Gräntzdörffer. G.P. 330,640, 11.4.20. Addn. to 311,212 (J., 1919, 550 A).

THE addition of second syrup and dissolved sugar to first products in the vacuum pan may be made before the formation of grain in the latter. The whole of the centrifugal runnings from first product sugar may be added to the next charge of first syrup, the major part being added before the formation of grain and the rest at the close of the boiling process.—J. H. L.

Root fruits [beetroots]; Method for extracting juices from ——. O. Mengelbier, Assr. to the Chemical Foundation, Inc. U.S.P. 1,372,891, 29.3.21. Appl., 11.5.14.

SEE F.P. 470,980 of 1914; J., 1915, 192.

Sugar beets. G. P. 324,641 and 325,392. *See* XIX A.

XVIII.—FERMENTATION INDUSTRIES.

Barley; Harvesting, storage and drying of ——. A. Cluss, W. Kluger, and V. Koudelka. Z. ges. Brauw, 1921, 4—18.

EXPERIMENTS similar to those of 1913 (J., 1921, 22 A) were carried out in 1914 with the same kind of barley. Owing to difference in weather and other conditions the 1914 barley was drier and richer in starch and extract than the 1913 crop, and its germinative power developed much more rapidly. By deferring the harvesting of the grain until it was "dead ripe" (a week after it had attained "full ripeness") the brewing quality of the barley was found to be improved. The advantages of drying the grain artificially, although well marked, were much less so than in the case of the previous crop, and were practically the same whether the drying was carried out immediately after threshing or after 6 weeks' storage. Storage in the ear proved less advantageous than in the earlier experiments. —J. H. L.

Hops; Drying of ——. A. H. Burgess. J. Inst. Brew., 1921, 27, 180—184.

To obtain data respecting the influence of various factors on the drying of hops under practical conditions, 11 kilns of various types were visited and records were made of 15 oastings. The data thus obtained are tabulated. The depth of the hops on the kilns varied from 11½ to 19 ins., artificial draught being used in most cases for the deeper loadings. The average temperature throughout the process ranged from 57° to 84° C., the most usual being about 70° C. The highest maximum recorded was 103° C. and the product in this case was considered satisfactory. The time required to complete the drying varied from 8½ to 15¾ hrs., average 10¾ hrs. The time taken does not depend solely on temperature, depth of load, and moisture-content of the hops. Hops wet with rain dried in some cases as rapidly as those picked in fine weather, and some oastings at comparatively high temperatures dried more slowly than others worked at a lower temperature. The most important factors are probably temperature and air supply, but the latter could not be estimated with any approach to accuracy. —J. H. L.

Yeasts; Break of ——. H. Lüers and R. Heuss. Z. ges. Brauw., 1921, 18—22.

THE flocculation or "break" of yeast, in aqueous suspensions, is closely related to the viscosity of the suspensions. Calcium or cerium chloride increased the viscosity and promoted flocculation to a much greater extent than equimolecular proportions of potassium chloride. The viscosity of 12%

suspensions of washed living yeast varied greatly with the reaction of the liquid, attaining a very well-defined maximum point when the reaction was slightly acid (p_H = about 4), and this point corresponded also with the maximum of flocculation. Similar suspensions of yeast killed by chloroform or heat showed no flocculation, and their viscosities were relatively low and varied to only a slight extent with the reaction of the liquid.—J. H. L.

Yeast; Cultivation of —— in solutions of purified nutrients. M. B. MacDonald and E. V. McCollum. J. Biol. Chem., 1921, **45**, 307—311.

It appears probable that yeast can synthesise the growth-stimulating principle known as vitamin B for purposes of its own growth.—J. C. D.

Iron; Determination of —— in wines. L. Mathieu. Ann. Chim. Analyt., 1921, **3**, 106. (*Cf.* Malvezin and Rivalland, J., 1921, 316 A.)

The author prefers the colorimetric method, using potassium thiocyanate; the ash of the wine is dissolved in warm 10% sulphuric acid, any ferrous iron oxidised by the addition of a few drops of nitric acid, and the solution then treated with thiocyanate.—W. P. S.

Sulphite spirit; Acetaldehyde content of ——. R. Sieber. Chem.-Zeit., 1921, **45**, 349—350.

The quantity of aldehyde present in sulphite spirit is proportional to the amount of sulphurous acid in the wort before fermentation; with an SO_2 content rising from 0·132 to 0·330 g. per 100 c.c., the aldehyde increases from 0·044 to 0·220 g. per litre of spirit. The SO_2 content does not alter appreciably during fermentation, and the portion which is presumably combined with the aldehyde is resistant to oxidation by aeration.—W. P. S.

Azotobacter. Kayser. *See* XVI.

Toxicity of phenol towards yeast. (1) Fraser. (2) Fulmer. *See* XIXB.

PATENTS.

Barley; Process for removing testinic acids and their compounds from ——. Nathan-Institut A.-G. G.P. 330,341, 24.5.17. Addn. to 327,498 (J., 1921, 235 A).

Barley is treated in the steep with dilute alkalis to dissolve the testinic acid, and then completely freed from the latter by washing. The treatment improves the flavour, head-retaining power, and stability of beer produced from the barley, and also renders low-grade barleys suitable for brewing. It may be applied also to oats.—J. H. L.

Glycerin; Production of —— by fermentation. A. Koch. G.P. 331,694, 20.11.17.

Sugar solutions of high concentration, *e.g.*, 40%, are fermented by large quantities of yeast, and alcohol is removed either continuously by means of a vacuum or from time to time by distillation under reduced pressure. The yield of glycerin amounts to at least 15% of the sugar fermented.—J. H. L.

Adhesive for belts and the like [from fermentation residues]. H. Haselberger. G.P. 328,881, 31.7.18.

Residues from the distillation of fermented liquids, containing glycerol and other hygroscopic substances, are treated with a protective agent against rust and made into a syrup with water or other liquid.—J. H. L.

Alcohol distillation. U.S.P. 1,372,465. *See* IIA.

Sugar beets. G.P. 324,641 and 325,392. *See* XIXA.

XIXA.—FOODS.

Milk; Vitamin content of ——. F. G. Hopkins. Biochem. J., 1920, **14**, 721—724.

The author has repeated and confirmed the results of his earlier experiments on the influence of the vitamins in very small quantities of milk on the growth of rats (*cf.* J. Physiol., 1912, **44**, 425). —J. C. D.

Vitamin A in butter; Effects of heat and aeration upon ——. F. G. Hopkins. Biochem J., 1920, **14**, 725—733.

The refining processes ordinarily employed for ground-nut (arachis) oil and palm kernel oil do not appear to affect the amount of vitamin present, which is very small. The vitamin present in butter fat is not appreciably destroyed by heat alone at temperatures up to 120° C., but is readily rendered inactive by aeration of the hot fat. The vitamin would appear to be a substance prone to oxidative change.—J. C. D.

Butter; Effect of heat and oxygen on the nutritive value of ——. J. C. Drummond and K. H. Coward. Biochem J., 1920, **14**, 734—739.

The vitamin in butter is rapidly destroyed by contact with air at high temperatures. Destruction occurs at temperatures as low as 37° C. if contact with air or oxygen is extensive. (*Cf. supra.*) —J. C. D.

Vitamin A in fats; Action of ozone on ——. S. S. Zilva. Biochem J., 1920, **14**, 740—741.

The vitamin A in butter and cod liver oil is rapidly destroyed by exposure to ozone. (*Cf. supra.*) —J. C. D.

Lard; Nutritive value of ——. J. C. Drummond, J. Golding, S. S. Zilva, and K. H. Coward. Biochem J., 1920, **14**, 742—753. (*Cf.* J., 1921, 81 T.)

The pig resembles other animals which can store up the vitamin A in their body fats, but this is only effected when the diet contains ample amounts of that factor. Fat derived from grass-fed pigs is fairly rich in the vitamin, but the amount may be considerably reduced by the processes of lard manufacture, which frequently involve contact of the hot fat with air.—J. C. D.

Vitamin A; Differentiation of —— from yellow plant pigments. M. Stephenson. Biochem. J., 1920, **14**, 715—720.

The author confirms Drummond's observation (J., 1919, 435 A) that the vitamin A is not one of the lipochromes. Butter fat filtered through charcoal loses its pigment, but retains the vitamin.—J. C. D.

Diets free from vitamin A; Critique of experiments with ——. T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1921, **45**, 277—288.

A general discussion of the technique employed for testing substances for the presence of the vitamin A, with especial reference to the divergent results obtained by different workers.—J. C. D.

Hay; Results of investigation into the self-heating of ——. G. Laupper. Landw. Jahrb. Schweiz, 1920, **34**, 1—54. Chem. Zentr., 1921, **92**, I., 162—163.

The view put forward is that the moisture from withered hay in a stack is able to activate the oxidases present in dried green hay with consequent chemical action and heat evolution. Micro-organisms play no part in the process. The following sequence of events was ascertained: At

20°—35°, activation of the oxidases, commencement of heating; at 35°—45°, caramelisation of sugar; at 45°—70°, evolution of ammonia and formic acid; at 60°—70°, acceleration of the exothermic reaction; at 70°—90°, decomposition of pectins, pungent odour; at 90°—100°, first decomposition of protein, formation of hydrogen sulphide and furfural; at 110°—170°, formation of nitric acid by oxidation of ammonia, explosive union between ammonium nitrate and caramel carbon; at 170°—250°, rapid progress of the exothermic reaction; at 250°—280°, decomposition of cellulose and protein, formation of hydrogen sulphide and furfural, ignition of pyrophoric iron; at 300°, region of inflammability through access of oxygen; at 320°—340° C., final decomposition of carbohydrates, formation of furfural and pyrophoric manganese. The injection of carbon dioxide into the stack does not remove the danger of fire.—J. H. J.

Reducing sugars in milk etc. Shaffer and Hartmann. *See* XVII.

Lactic acid in baking powder. Hartwig and Saar. *See* XX.

Patents.

Concentration of fruit juices in the manufacture of grape honey and fruit syrups; Process and apparatus for the ——. E. Barbet et Fils et Cie. E.P. 135,175, 6.11.19. Conv., 9.11.18.

For the economical concentration of fruit juices in vacuum multiple-effect apparatus, the different effects are used for different juices according to their sensitiveness to heat. Thus the first effect may be used for sulphured juice from white grapes which, for the end in view, is not injured by boiling at 70° C. or above, whilst the second effect is used for the more sensitive juice from red grapes, which would be impaired by boiling at temperatures above 55° C. Each effect may comprise more than one evaporator, and the concentration of each juice may be carried out in two stages between which the juice is allowed to cool and deposit tartar. An arrangement of apparatus for carrying out the process is described.—J. H. L.

Fruit and other vegetable matter; Method of and apparatus for the extraction of juices, pectin, and the like from ——. J. Nicholson. E.P. 159,311, 24.11.19.

Pomace or other suitable material, preferably freed from sugar, is introduced into a strainer immersed in water, and simultaneously heated and agitated, *e.g.*, by injection of steam, to obtain an extract suitable for use in the manufacture of jam. The apparatus comprises a bag-shaped strainer of copper gauze, suspended in a pulp container, which is provided with a steam-tight cover and may be fitted with perforated steam pipes around and within the strainer.—J. H. L.

Milk food. C. S. Townsend. E.P. 159,362, 10.12.19.

Liquefied jelly obtained from *Chondrus crispus* (Irish moss) is emulsified with whole-cream milk, and the product is dried.—J. H. L.

Food and food products; Preparation of ——. J. G. Goodhue and H. L. Trube U.S.P. (A) 1,365,909 and (B) 1,365,910, 18.1.21. Appl., 4.10. and 19.11.17.

(A) A drying chamber is provided with passages for conveying a number of air currents over material to be dried and back again. Means are provided for inducing the air currents and for heating them independently of the drying chamber. Mechanical means are provided within the chamber for keeping the foodstuff moving forward during the process. (B) A drying chamber is divided into smaller chambers by transverse partitions. Each chamber contains a receptacle for the material to be dried with its end placed at the transverse partition, which is provided with openings placed alternately on opposite sides of the receptacles and forming passages between adjacent chambers, so as to provide a path for a drying current across the receptacles. An air current is circulated by means of a blower at one end of the main chamber and a heater at the opposite end.—J. H. J.

Flour and other cereal products; Process of bleaching and maturing ——. J. C. Baker. U.S.P. 1,367,530, 8.2.21. Appl., 14.2.20.

Nitrogen trichloride gas is passed through the flour.—J. H. J.

Coffee extract; Method of making water-soluble —— and the product. Method of adding segregated aromas to coffee extract. D. S. Pratt and C. W. Trigg, Assrs. to J. E. King. U.S.P. (A) 1,367,715 and (B) 1,367,716, 8.2.21. Appl., 31.5.18.

(A) The aroma is separated from a coffee infusion and is brought into contact with lactose which absorbs it. The infusion is evaporated to dryness and the impregnated lactose is mixed with the residue. (B) A coffee extract is sprayed with a solution of coffee aroma in a volatile solvent. —J. H. J.

Aromatic and flavouring constituents; Process for recovery of ——. Process for recovery of escaping aromas of food etc. Recovery of aromas etc. escaping during comminution of coffee-beans. C. W. Trigg, Assr. to J. E. King. U.S.P. (A) 1,367,724, (B) 1,367,725, and (C) 1,367,726, 8.2.21. Appl., (A, B) 19.11.17, (C) 31.5.18.

(A) An infusion of roasted ground coffee is evaporated to dryness, the vapour given off being condensed. From the condensed product the caffeol is separated by a solvent and is added to the coffee extract, the solvent being subsequently removed. (B) A coffee infusion is evaporated in a vacuum, the vapours condensed, and the caffeol extracted. The chamber is then exhausted and the gases passed into a closed chamber where they are compressed above atmospheric pressure and passed through a caffeol solution, and then passed into a coffee extract chamber under pressure. When the extract has absorbed the caffeol solution, the pressure is reduced and the solvent allowed to escape. (C) Roasted coffee beans are ground in a closed chamber from which air is excluded. An inert gas is passed through the chamber to remove the aroma and brought into contact with a water-soluble coffee extract, which absorbs the aroma.—J. H. J.

Sterilising milk and other liquids; Process and apparatus for ——. O. Lobeck, Assr. to The Chemical Foundation. U.S.P. 1,369,345, 22.2.21. Appl., 18.2.15.

The milk, by a rotary device, is formed into an extremely thin layer, and in this condition is heated under reduced pressure at a temperature below its boiling point. (*Cf.* G.P. 306,924; J., 1918, 669 A.)—J. H. L.

Drying food products and other materials; Apparatus for dehydrating or ——. W. D. Edwards. U.S.P. 1,369,411, 22.2.21. Appl., 26.2.19.

The apparatus comprises a number of independent chambers arranged side by side, perforated supports for the material to be dried extending diagonally across the chambers so as to divide each into two compartments larger at one end than the other, and means for introducing air into all the chambers at one end, for controlling the air-inlet of each chamber, and for introducing moisture into the air at the inlet ends of the chambers. —J. H. L.

Fish; Food obtained from —— and process of making the same. S. Satow. U.S.P. 1,370,049, 1.3.21. Appl., 5.5.17.

THE cooked residue from the manufacture of fish oil is crushed or ground to a paste, dried *in vacuo* below 50° F. (10° C.), ground to powder, and subjected to the action of a proteolytic enzyme, after which the soluble protein is extracted with water, evaporated *in vacuo* at a low temperature, and powdered.—J. H. L.

Evaporated vegetables; Method of preparing ——. R. S. Wittenberg, Assr. to The Pacific Evaporator Co. U.S.P. 1,372,112, 22.3.21. Appl., 17.4.19.

THE vegetables are sliced, the cut surfaces subjected to the abrasive action of a jet of fluid of such force and so directed as to remove the free substances exposed by the slicing, and the slices then dehydrated.—A. de W.

Culinary product. Edible oil material and process of producing same. C. Ellis. U.S.P. (A) 1,372,614 and (B) 1,372,615, 22.3.21. Appl., 25.1.19 and 24.4.18.

(A) A FOOD product (nut butter) of a consistency about that of butter is produced by mixing several oils (coconut and peanut oils) together and completely hydrogenating them with the aid of a catalyst. (B) A product of lard- or butter-like consistency is formed from a mixture of a normally liquid nut oil, hydrogenated to a hardness at least as great as that of tallow, with a substantially greater amount of an unhydrogenated nut oil having an iodine value below 25 and a saponification value above 240.—B. M. V.

Sugar beets; Process for purifying and deodorising comminuted ——. Betavit-Ges. m.b.H. G.P. (A) 324,641, 14.12.17, and (B) 325,392, 12.11.18.

(A) STEAM at 100°—104° C. is passed through the material until the flavour and odour of beets have been removed. The product has a pleasant vanilla-like odour and may be used for the production of beer or other beverages. Sugar beet flour may be obtained by atomising and desiccating the juice, and the slices, separated from the juice, may be used for the preparation of foodstuffs or fodder. (B) A current of dry gas, *e.g.*, air or carbon dioxide, is employed instead of steam, whereby dilution of the material is avoided.—J. H. L.

Maize meal or maize grits; Removal of bitter substances from ——. P. Schuffelhauer and O. Fauser. G.P. 328,425, 1.11.16.

THE material, enclosed in a bag or similar container, is treated several times with boiling brine and then allowed to cool and taken out of the container. The skin which has formed on the surface is removed and the material ground and dried in hot air. The maize oil may be extracted from the brine and the skin.—J. H. L.

Fodder grasses; Process for rendering withered —— stable by spontaneous fermentation. "Herba" A.-G. G.P. 328,781, 31.5.17. (*Cf.* G.P. 305,562; J., 1918, 960 A.)

IN order to secure uniform fermentation throughout the whole mass of fodder, the layers of which are exposed to the cooling influence of the floor, walls, and roof of the containing chamber, the fodder is treated with lactic bacteria; usually 150—180 c.c. of a pure culture in whey is sufficient for 1 cb. m. of fodder.—J. H. L.

Straw; Process for the preparation of digested ——, in which the production of waste liquors and losses by washing are avoided. W. Thomann. G.P. 328,782, 16.5.18.

THE alkaline digested straw is neutralised with sour whey, sour buttermilk, or sour skim milk. The lactates formed improve the flavour of the fodder. —J. H. L.

Straw (e.g., from cereals or leguminous plants); Production of fodder from —— by digestion with ammonia. E. Beckmann. G.P. 332,363, 25.2.19.

THE comminuted straw is digested below 80° C. with aqueous ammonia, preferably of 0·5—8% concentration, or with equivalent quantities of ammonium salts or mixtures which produce ammonia. —J. H. L.

Fodder from straw; Preparation of a ——. Veredelungsges. für Nahrungs- und Futtermittel m.b.H. G.P. 333,746, 29.3.18. Addn. to 305,641 (J., 1919, 789 A).

THE straw is digested with a solution of an alkali sulphide, with or without the addition of an alkali hydroxide instead of with an alkali solution as described in the chief patent.—L. A. C.

Fruit and vegetable refuse of all kinds; Complete utilisation of ——. Malz- und Nährextrakt-Werke A.-G. G.P. 331,005, 9.6.18.

WASTE materials such as pea shells, banana skins, and the like, are crushed and then extracted by boiling and pressure if necessary. The extract is concentrated and employed as a foodstuff and the residue is further digested with alkalis in order to obtain a liquid cattle fodder and a fibrous residue. Fibres thus obtained from asparagus waste can be used for textile purposes.—J. H. L.

Quinoa; Preparation of a food product rich in protein from ——. E. Heilmann. G.P. 331,547, 11.8.18.

A FOODSTUFF and also an oil and saponin are obtained by drying the finely ground material below 60° C., extracting with dry ether or other fat solvent, and then treating the residue with alcohol, *e.g.*, methyl alcohol, at 60° C. or under to extract the saponin.—J. H. L.

Bread; Process for increasing the yield of ——. E. C. Sutherland, Assr. to Naaml. Vennoots. Ind. Maatschappij v.h. Noury en van der Lande. U.S.P. 1,372,842, 29.3.21. Appl., 18.9.17.

SEE E.P. 115,410 of 1917; J., 1919, 266 A.

XIXB.—WATER PURIFICATION; SANITATION.

Water analysis. Determination of hardness. L. W. Winkler. Z. angew. Chem., 1921, 34, 115—116.

THE following modification of Wartha's method is recommended: 100 c.c. of water is treated with 2 drops of methyl orange solution and the "alkalinity" is titrated with $N/10$ hydrochloric acid. The mixture is then transferred to a 200 c.c. cylinder, 50 c.c. of $N/10$ sodium hydroxide-sodium carbonate solution is added, and the whole diluted to 200 c.c. After about 24 hrs., 100 c.c. of the clear solution is drawn off and the excess of alkali is titrated with $N/10$ hydrochloric acid.—W. P. S.

Water analysis. L. W. Winkler. Z. angew. Chem., 1921, 34, 143.

To effect saving in the use of ethyl alcohol, soap solution for the determination of hardness in water may be prepared with propyl alcohol, the palmitic acid or oleic acid being dissolved in this solvent and neutralised with potassium hydroxide solution. Directions are also given for the determination of calcium and magnesium in waters. —W. P. S.

Phenol and phenol salt solutions; Methylene blue as an indicator of the toxicity of —— towards yeast. C. G. Fraser. J. Phys. Chem., 1921, **25**, 1—9.

SOLUTIONS of phenol and of phenol and sodium chloride, which are in equilibrium with solutions of phenol in toluene or kerosene (*cf.* J., 1920, 799 A), are isotoxic with these towards yeast cells if ability to stain with methylene blue be adopted as a criterion of death. If, however, inability to form colonies on wort-agar be taken as indication of death, the solutions containing sodium chloride are more toxic. The inability to form colonies on wort-agar seems to mark an earlier stage in the loss of vitality, and the time it takes to reach this stage seems to depend on other factors than the temperature and chemical potential of the phenol in the solution, amongst them the osmotic pressure of the toxic liquid.—J. C. K.

Phenol; Effect of alcohol on the toxicity of —— toward yeast. E. I. Fulmer. J. Phys. Chem., 1921, **25**, 10—18. (*Cf. supra.*)

YEAST cells derived from one original cell, and grown under the same conditions in wort, may show very different degrees of resistance to phenol. When wort is seeded with yeast, the first evidence of the fermentation is the formation of white flecks or foam on the surface. The time at which these flecks appear is quite definite. After this first stage, another is reached of active fermentation; while, in a third stage, the fermentation grows slower and finally ceases. When the alcohol produced by fermentation has reached a certain concentration, the cells are much more resistant to phenol than normal cells. If alcohol is added to the wort before seeding with yeast, the formation of abnormal "resting cells," which appear only in the third stage mentioned above, is hastened. By taking as a criterion of death the inability to grow colonies on wort-agar, it was found that a solution containing water, phenol, and 3·75% of alcohol is more toxic to normal yeast cells than a chemically equivalent solution without alcohol; but if, on the other hand, the ability to stain with methylene blue is taken as a criterion, the solutions are found to be equally toxic. Immersion in 8% solutions of alcohol in water increases the number of cells capable of staining with methylene blue, and, consistently with this, a solution containing phenol, water, and 7·5% of alcohol increases the percentage of stained cells more rapidly than a chemically equivalent solution of phenol in water.—J. C. K.

Strawboard factory waste waters. Hermann. *See* V.

PATENTS.

Water; Apparatus for separating gases, iron, manganese, and other hardening admixtures from ——. H. Wehner. E.P. 7272, 14.5.15.

THE water in a finely divided state is mixed with air in a chamber under partial vacuum, the air serving to absorb deleterious gases and being then separated together with such gases. The admixture of the air and water is effected in a "diffuser," comprising a rotor having blades which work between fixed blades in a casing through which the water is drawn by suction, a suitable quantity of air being admitted through numerous small orifices in the circumference of the diffuser. From the diffuser the aerated water passes to a chamber under partial vacuum where the added air is again separated from the water, which is then drawn through a strainer (composed of slag or of a substance which, if desired, will effect the separation of iron etc.) by means of a centrifugal pump on the same shaft as the rotor of the diffuser, and delivered to a suitable tank. If desired a pipe having a series of constrictions, or closely packed with balls, and provided with a porous cell through which air may be forced, may be interposed between the diffuser and the vacuum chamber.
—G. F. M.

Water; Process for the sterilisation and purification of —— [by means of decolorising carbon]. J. N. A. Sauer. E.P. 155,610, 20.6.19.

WATER is treated with finely divided decolorising carbon, such as Eponit or Norit, which has previously been subjected to the action of alkalis and/or acids and/or high temperatures; *e.g.*, the carbon may be heated with dilute sodium hydroxide or ammonia solution, then with dilute hydrochloric or other volatile acid, and finally heated alone to 1200° C. or above.—J. H. L.

Water; Treatment of —— for softening, sterilising, and like purposes. H. J. Magrath. E.P. 158,498, 13.9.20.

THE plant consists of a tank divided into two parts, the lower of which contains a filtering medium, such as natural or artificial zeolite, and the upper a chamber for a regenerating solution with a removable filter and a ball cistern. The two parts of the tank are connected by pipes with a cock which can be set so as to pass either the water to be treated or the regenerating solution through the lower part. The plant is connected with the main water supply pipe in such a manner that it may be cut out of the circuit without disturbing any of the connexions. It is specially suitable for use in inhabited buildings. (*Cf.* E.P. 18,867 of 1914; J., 1915, 1030.)
—J. H. J.

Sterilising liquids [water]; Process and apparatus for —— applicable also to like operations. W. Paterson. E.P. 158,578, 1.8.17.

CHLORINE is passed through a measuring valve to an absorber to which a regulated amount of water is also admitted. The solution obtained accumulates in a reservoir, from which it passes to a feeding tank with a tapered outlet valve controlled by a float resting in the main body of water to be treated as it flows over a weir. In this way the flow of the main body of water determines the amount of solution to be added. When the accumulation of solution in the reservoir reaches a certain amount, the supply of gas and water is automatically cut off and is not resumed until the accumulation is reduced again.—J. H. J.

Water; Process for the softening or purification of ——. B. F. Rushton. E.P. 158,620, 3.11.19.

A TANK with curved bottom contains the water to be treated. Electrodes of carbon, zinc, or iron are suspended from a bar across the top of the tank. In the lower portion of the tank is an agitator worked by an electric motor mounted above the tank. A current of about 25 volts is passed through the water for about 1 hr., after which the electrodes are removed, slaked lime is introduced in the proportion of 3 lb. to 1000 galls. of water, and the agitator is set in motion for 10 mins. The water is then allowed to stand for about 1 hr. and is run off through a valve in the lower portion of the tank. The sludge is removed from the bottom of the tank through a sluice valve. The process is suitable for the treatment of any mineral water except sea water.—J. H. J.

Water; Purification of —— by means of barium carbonate and quicklime. H. Riesert G.m.b.H. G.P. 333,994, 25.1.18.

BARIUM carbonate is suspended in a rising column of water which, at the moment when the reaction between the barium carbonate and the sulphates in the water is complete, is treated with quicklime,

which tends to prevent the fine particles of barium sulphate from being carried over with the purified water.—A. R. P.

Sewage and analogous liquids; Apparatus for the purification of ——. Air distributing apparatus connected with the purification of sewage and analogous liquids. W. T. Lockett and A. Herring-Shaw. E.P. (A) 156,816 and (B) 156,817, 11.8.17.

(B) An aerating device for the aeration of sewage consists of one or more revolving arms made in the form of a sector of a circle and projecting horizontally from a central pivot in a treatment tank. The arm is of hollow section and its upper surface is of porous material. It is supplied with compressed air from a central shaft or otherwise. The upper surface of the arm may be of a continuous flat form or may be composed of units of circular or other shape, graduated in size so as to give a sufficient air discharge at any position between the centre of rotation and the extremity of the arm. In another form, the arm consists of a pipe with a series of short branch pipes from its upper side terminating in flat circular air chambers with porous upper surfaces of graduated diameter according to their distance from the centre of rotation. (A) In order to lift deposited solids from the floor of the tank and bring them into the sphere of action of the air supply, the advancing side of the rotating arm is made with an inclined surface, sloping forwards from above downwards.—J. H. J.

Waste water from gas-works and tanneries; Process for rendering innocuous ——. C. Bozenhardt. G.P. 333,703, 14.3.19.

Ammoniacal waste water from gas-works is allowed to mix with the waste water from chrome leather tanneries containing salts of chromium, in order to recover the latter as chromium hydroxide and to render the resulting liquid safe for direct discharge into a river.—A. R. P.

Insecticides, fungicides, animal dips; Materials for use as —— and like purposes. A. E. Hawker. E.P. 160,511, 15.12.19.

Light wood oil, obtained by the redistillation of the tarry layer formed by the controlled distillation of hard woods at an initial temperature of 300° F. (about 150° C.), raised subsequently to 800° F. (about 430° C.), is used in combination with soap or other emulsifying agent, in tablet, powder, or liquid form, as an insecticide, fungicide, etc. The fraction of the distillate employed is preferably that collected up to the point at which the sp. gr. reaches about 0·98, but other fractions may be used if desired. A maximum of 50% of kieselguhr, fuller's earth, or other absorbent is used in making the powder form of the preparation, whilst water, glycerin, or other solvent is employed for the liquid form.—G. F. M.

Sheep dips and cattle washes. J. McDougall and F. Howles. E.P. 160,597, 7.1.20.

A fluid sheep dip or cattle wash containing a high concentration of sodium arsenite is prepared by dissolving arsenious oxide in one-fourth or more of its weight of sodium hydroxide in concentrated aqueous solution, adding a colloid, such as hydrolysed starch or glue, casein, or soap, to the extent in the case of the hydrolysed starch of about one-twentieth of the weight of the arsenic, and evaporating the whole to a concentration of 50% or more of arsenious oxide. The mixture remains quite fluid on cooling and can be more easily diluted to the required strength for use than concentrated sodium arsenite preparations in the solid form.
—G. F. M.

Parasiticide for plants and animals. Farbenfabr. vorm. F. Bayer und Co. G.P. 333,327, 4.7.19.

The parasiticide consists of an ether containing at least one aralkyl group, such as dibenzyl ether, chlorobenzyl ethyl ether or xylyl phenyl ether. The ethers may be used in the liquid or vapour form, as pastes, absorbed in a porous powder, in soaps or ointments, or as solutions in alcohol or ethyl acetate, if necessary also in admixture with other substances.—A. R. P.

Phenols; Preparation of solid mixtures [disinfectants] soluble in water and containing ——. Chem. Fabr. von Heyden, A.-G. G.P. 331,583, 23.3.13.

Solid, insoluble or only slightly soluble complex compounds of phenols with alkali salts of the same or other phenols, are mixed with such solid salts of organic acids as yield aqueous solutions capable of dissolving phenols. The products dissolve readily in water and yield clear solutions possessing only slight alkalinity, and such alkalinity may be avoided by incorporating with the original mixture a solid acid or acid salt which forms with the free alkali a salt exerting a solvent action on the phenols.—J. H. L.

Fatty matter from garbage. U.S.P. 1,372,479. *See* XII.

Fumigant paint. U.S.P. 1,373,499. *See* XIII.

Treatment of seeds. G.P. 327,310. *See* XVI.

Purifying liquors. E.P. 155,609 and 155,611. *See* XVII.

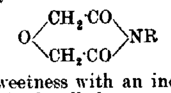
XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Antipyrine; Compounds of —— with mercury. E. Oliveri-Mandalà. Gazz. Chim. Ital., 1921, **51**, I., 125—130.

Antipyrine (1 mol.) combines readily with unstable mercury compounds (1 mol.), such as HgCl.OH, HgI.OH, and $HgCl.NH_2$; the antipyrine apparently behaves as an unsaturated compound, the nitrogen atom joined to a methyl group uniting with the negative portion of the added molecule. Pyramidone (dimethylaminoantipyrine) combines with mercuric chloride, but not with $Hg(OH)_2$, HgCl.OH, or $HgCl.NH_2$, replacement of the methinic hydrogen of the antipyrine molecule by the dimethylamino-group present in pyramidone evidently destroying the mobility of arrangement of the valencies of the nucleus. (*Cf.* J.C.S., May.)—T. H. P.

Sweetening materials; Cyclic imide ethers of diglycollic acid as ——. M. Sido. Ber. deuts. Pharm. Ges., 1921, **31**, 118—129.

Whilst the substitution of the imino hydrogen in saccharin by alkyl groups entirely destroys the sweetness of that substance, the position is completely reversed in the case of diglycolimide, which, though itself tasteless, yields alkylimides of the general formula



increasing in sweetness with an increasing number of carbon atoms in the alkyl group up to a maximum in the N-propyl derivative. The aryl derivatives on the other hand are almost tasteless. The substituted imides were prepared by heating the acid alkylamine or arylamine diglycollates in a vacuum, whereby water was expelled, and the residual imide was purified by distillation under reduced pressure

and crystallisation if necessary from absolute alcohol. Diglycolmethylimide and diglycolethylimide are solid crystalline substances, whilst the N-propyl- and N-butylimides are colourless, oily liquids having an intensely sweet taste. All four substances are extremely hygroscopic, and as they are rapidly reconverted by the action of water into the tasteless alkylamine hydrogen diglycollates, they can have no practical application as sweetening agents. (*Cf.* J.C.S., June.)—G. F. M.

Catalysts; Influencing of the activity of ——. II. Reduction of acid chlorides to alcohol and ester. K. W. Rosenmund, F. Zetzsche, and F. Heise. Ber., 1921, **54**, 638—647. (*Cf.* J., 1921, 321 A.)

THE reduction of benzoyl chloride with the aid of uninfluenced catalysts leads mainly to the production of hydrocarbons. In the presence of sulphur-nitrogen compounds, aldehydes are formed. The joint influence of toluene and xanthone causes benzyl benzoate to be the main product. In xylene solution, benzyl esters undergo reductive fission into alcohol and toluene, which is, however, inhibited by addition of the latter. Quinoline favours the production of benzyl alcohol, dibenzyl ether being formed simultaneously. (*Cf.* J.C.S., June.)—H. W.

Glyoxal; Preparation of —— by the action of acetylene on gold chloride or bromide. K. Kindler. Ber., 1921, **54**, 647—649.

GOLD is precipitated quantitatively from aqueous solutions of auric halides by acetylene if the gold content does not greatly exceed 1·5%. The acetylene is converted into carbon dioxide (12%) and glyoxal (about 86%), the latter appearing to be the sole organic product of the change. The finely-divided gold can be readily re-converted into the halide by treatment with chlorine or bromine.—H. W.

Oxalic acid; Volumetric determination of ——. A. Abelmann. Ber. deuts. Pharm. Ges., 1921, **31**, 130—131.

To the oxalic acid or oxalate solution in a 100 c.c. flask, 30—40 drops of $5N$ nitric acid, and a measured excess of $N/10$ mercuric nitrate solution, containing sufficient nitric acid to produce a clear solution, are added, followed by about 50 c.c. of saturated potassium nitrate solution and sufficient water to make 100 c.c. After standing for 15 mins., the solution is filtered and an aliquot portion of the filtrate titrated with $N/10$ ammonium thiocyanate with ferric ammonium sulphate as indicator.
—G. F. M.

Lactic acid; Detection of ——. L. Hartwig and R. Saar. Chem.-Zeit., 1921, **45**, 322.

ABOUT 0·2 c.c. of a solution containing not more than 0·2% of lactic acid is mixed with 2 c.c. of concentrated sulphuric acid, the mixture heated at 100° C. for 2 mins., cooled, and treated with 2 drops of 5% alcoholic guaiacol solution; a red coloration is obtained. Formic, acetic, malic, benzoic, and salicylic acids do not give a coloration with the test; citric acid yields a yellow, tartaric acid a faint pink, and tannin a blackish-violet coloration. To detect lactic acid in baking powder, the sample is moistened with water, acidified with phosphoric acid, then mixed with sand and plaster of Paris, and the mixture extracted with ether; the residue obtained on evaporating the ethereal solution is diluted with water and tested as described.
—W. P. S.

Calcium salt; A new ——. L. Gaucher and G. Rollin. Comptes rend. Soc. Biol., 1921, **84**, 303—304. Chem. Zentr., 1921, **92**, I., 562.

BY the action of phosphorus tri-iodide on concentrated lactic acid a substance of the formula, $C_6H_9O_6P$, is obtained. It melts at 120° C., and is converted by water into the tribasic dipropanoloiphosphorous acid, $HO.P.(O.CH(CH_3).CO_2H)_2$. The calcium salt of this acid, $Ca_3(C_6H_8O_7P)_2,8H_2O$, is very suitable for subcutaneous injection. In neutral or weak acid solution it remains unchanged in the cold, but in presence of alkali it is converted into insoluble calcium phosphite.—G. F. M.

Acetone; Action of ammonia on ——. T. S. Patterson and A. McMillan. Chem. Soc. Trans., 1921, **119**, 269—271.

IN the course of the preparation of diacetonamine from acetone and ammonia by the usual method, what appears to be an intermediate product of the constitution,

$$CH_3.CO.CH_2.C(CH_3)_2.NH.C(CH_3)_2.NH_2,$$

was deposited in thin prismatic crystals when the ammoniacal acetone was cooled in a freezing mixture. The substance melts at 45° C., and behaves as a di-acid base when titrated with hydrochloric acid in aqueous solution. A monohydrochloride is precipitated when the ethereal solution is treated with dry hydrogen chloride. The substance readily decomposes, and it is suggested that when the reaction mixture is worked up in the usual way it is decomposed by the treatment with oxalic acid into ammonium oxalate and diacetonamine hydrogen oxalate.—G. F. M.

Camphor; Reaction for distinguishing natural and artificial ——. Utz. Farben-Zeit., 1921, **26**, 1065.

LENZ's hydrochloric acid reaction (J., 1911, 766) for distinguishing between natural and artificial camphor is untrustworthy, whilst the colour reactions with fuming nitric acid and sulphuric acid observed by Zimmermann (Apoth.-Zeit., 1920, 35, 382) were most probably due to fortuitous impurities. The author recommends the vanillin-hydrochloric acid and vanillin-hydrochloric-sulphuric acid tests for distinguishing between natural and synthetic camphor (*cf.* Bohrisch, J., 1915, 1224). In cases where determinations of synthetic camphor in natural camphor are required, polarimetric examination should be resorted to.
—A. de W.

PATENTS.

Valeric acid and alkaline valerates; Manufacture of ——. Darrasse Frères et Cie., and L. Dupont. E.P. 137,064, 24.12.19. Conv., 3.12.18.

SALTS of valeric acid are obtained by heating an excess of amyl alcohol with sodium or potassium hydroxide in an autoclave provided with an adjustable discharge valve for the escape of hydrogen at 235°—240° C. under 18 atm. pressure. When the whole of the alkali has been converted into valerate according to the equation $C_5H_{12}O+NaOH=C_5H_9O_2Na+2H_2$, the excess of amyl alcohol is distilled off in a current of steam, and valeric acid is isolated from the resulting alkali valerate solution by the usual methods.—G. F. M.

Acetaldehyde from acetylene; Process for the manufacture of ——. Chem. Fabr. Griesheim-Elektron. E.P. 143,891, 27.5.20. Conv., 10.8.16.

IN the conversion of acetylene into acetaldehyde in presence of mercury compounds the catalyst is continuously regenerated in the absorption vessel itself by an anodic oxidation process in which the reduced mercury forms the anode, the acid reaction liquid the electrolyte, and mercury, lead, or platinum the cathode. The cathode may either be arranged in a chamber closed by a diaphragm from which the hydrogen is discharged, or it may be placed without a diaphragm in the acid reaction liquid, the hydrogen which gradually accumulates in the circulating gas being removed at intervals. By this process larger quantities of mercury salt,

exceeding 10% of the weight of the acid reaction liquid, can be employed, with a consequent increase in the rate of absorption of the acetylene.
—G. F. M.

Borneol; Manufacture of ——. Fabr. de Prod. Chim. de Thann et de Mulhouse. E.P. 144,604, 8.12.19. Conv., 12.6.19.

TURPENTINE or crude pinene is heated with a quarter of its weight of tetrachlorophthalic acid in a reflux apparatus with continual stirring for 12 hrs. at 106°—108° C. The temperature is then slowly raised to 140° C., at which it is maintained for 6 hrs. After cooling, the unattacked terpenes are distilled off with steam or in a vacuum, and the residue, which forms a glassy mass consisting of dibornyl tetrachlorophthalate, is hydrolysed with alcoholic sodium hydroxide. The borneol, precipitated by the addition of water, is purified by the usual methods. It is optically active, and, unlike the product obtained by the action of other organic acids on pinene, it is quite free from isoborneol. The yield may be as high as 18% of the crude pinene used, and in addition there is a considerable quantity of pinene recovered, which, if desired, can be returned to the manufacture. The tetrachlorophthalic acid can be almost quantitatively recovered.—G. F. M.

Isobornyl ester and camphene; Conversion of pinene compounds into a mixture of ——. L. G. Wesson. U.S.P. 1,372,382, 22.3.21. Appl., 30.6.19.

PINENE hydrochloride or hydrobromide when heated with a carboxylic acid in presence of not more than 5% of zinc is converted into a mixture of an isobornyl ester and camphene.—G. F. M.

p-Aminophenol and of its O-alkyl ethers; Manufacture of derivatives of ——. E. Kolshorn. E.P. (A) 145,614, 29.6.20. Conv., 13.6.19. (B) 155,575, (C) 155,576, 24.11.20. Conv., 12.12.19.

(A) WATER-SOLUBLE derivatives of *p*-aminophenol or of its O-alkyl ethers are obtained by their conversion into N-dihydroxypropyl compounds of the general formula,

$$RO.C_6H_4.NH.CH_2.CH(OH).CH_2OH,$$

by causing the amino-compounds to react either directly or in a neutral solvent with monochlorhydrin, or with epihydrin alcohol, in the former case either with or without the addition of an alkali hydroxide. Thus 22 gr. of *p*-aminophenol when gently heated with 15 g. of epihydrin alcohol (glycide) in benzene solution is converted into N-dihydroxypropyl-*p*-aminophenol, m.p. 192° C., readily soluble in water, giving a solution which has a powerful reducing action on silver salts, and is specially suitable as a photographic developer. N-Dihydroxypropyl-*p*-phenetidine, m.p. 93° C., is obtained by the action of α-monochlorhydrin (11 g.) on *p*-phenetidine (14 g.) in presence of alcoholic potassium hydroxide. It is easily soluble in water and has valuable therapeutic properties. (B) The same derivatives of *p*-aminophenol and its ethers are obtained by condensing the bases with epichlorhydrin, with or without the addition of a neutral solvent, and treating the chloro-compound, $RO.C_6H_4.NH.CH_2.CH(OH).CH_2Cl$, produced, with the theoretical amount of alcoholic potassium hydroxide. (C) Instead of epichlorhydrin, αα- or αβ-dichlorhydrin may be used in presence of pyridine or alcoholic potassium hydroxide to eliminate the halogen acid, the chloro-intermediate product being treated with alkali hydroxide as before to eliminate chlorine.—G. F. M.

Glandular extractive product [from the infundibular lobe of the pituitary gland]; Process of manufacturing ——. A. M. Clover, Assr. to Parke, Davis and Co. U.S.P. 1,373,551, 5.4.21. Appl., 3.3.13.

THE gland is extracted with hot, acidified water, insoluble material is separated from the solution, and the active constituent is precipitated by saturating the solution with sodium chloride.
—L. A. C.

Trihydroxyisopentane; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 309,111, 12.8.17.

TRIHYDROXYISOPENTANE (dimethylglycerol) is obtained by the oxidation of 3-methylbutenol, or by the saponification of the corresponding chlorine derivative. It is a solid, m.p. 49° C., b.p. 122° C., and is more hygroscopic and more strongly bactericidal than glycerin.—B. V. S.

Anti-gonorrhœa preparation; Production of ——. P. Bergell. G.P. 330,348, 1.4.19.

A CULTURE of gonococci is prepared under optimum conditions at 36° C. and then the organisms are killed by maintaining a temperature of 41°—42° C. for a long time. The destroyed organisms are suspended in physiological salt solution with the addition, if necessary, of a disinfectant. If the temperature is raised to 45° C. the anti-toxic properties of the culture are reduced.—H. J. H.

Ovaries and similar organs; Preparation of nitrogenous compounds from ——. L. Seitz and H. Wintz. G.P. 332,165, 25.1.16. Addn. to 320,857.

THE method of the chief patent (J.,1920, 675 A), is extended to the ovary and the placenta, the former yielding a substance with a preventive effect and the latter one with a loosening effect on menstruation. The latter substance may also be obtained in pure form from the dried, powdered organ by extraction with alcohol and chloroform.—B. V. S.

Glycerin substitute [from lactates]. Chem. Fabr. vorm. Goldenberg, Geromont und Co. G.P. 332,167, 9.8.18. Addn. to 303,991 (J., 1920, 756 A).

MIXTURES of alkali lactates with lactates of suitable di- and trivalent metals are employed. Lactates of calcium, zinc, and magnesium obtained in the manufacture of lactic acid may thus be utilised.
—J. H. L.

N-Alkyl-acylhomopiperonylamines; Manufacture of ——. E. Merck, Chem. Fabr. G.P. 332,474, 26.3.12.

THE alkali salts of N-acylhomopiperonylamines are treated with alkylating agents. For example, by condensing the potassium compound of formylhomopiperonylamine (obtained by treatment with potassium in toluene solution) with methyl iodide, methylformylhomopiperonylamine, a thick, strongly refracting oil, b.p. 194° C. at 6 mm., is formed quantitatively. The sodium compound prepared in a benzene solution may be allowed to react in a similar manner on methyl chloride.—C. A. C.

Fatty acids and aldehydes; Manufacture of ——. C. Harries, R. Koetschau, and E. Albrecht. G.P. 332,478, 11.6.16. Addn. to 324,663 (J. 1920, 765 A).

THE decomposition of the ozonides is effected by reducing agents, as sulphur dioxide, sulphites, zinc or the like and acids. The dark-coloured soaps and acids obtained by alkali fusion of hydrocarbons (G.P. 314,745; J., 1920, 151 A) may also be transformed into ozonides and the latter decomposed by steam, caustic alkali, or sulphuric acid, or by reducing agents, as sulphur dioxide, sulphites, zinc, and acids. Technically valuable light yellow to colourless products of low molecular weight are formed, consisting chiefly of carboxylic and dicarboxylic acids. During the action of ozone on the dark, alkaline solutions, *e.g.* of acid resins from the re-

fining of petroleum, the ozonides are decomposed *in statu nascendi*.—C. A. C.

Bismuth-alkali iodide solutions; Preparation of —— for therapeutic use. Chem. Fabr. auf Aktien (vorm. E. Schering). G.P. 332,552, 21.4.16.

THE capacity to precipitate albumin or gelatin from solution is removed by the addition to the bismuth iodide of a large excess of an alkali iodide and a small quantity of an acid such as tartaric, glycollic, citric, lactic, or hydriodic acid. The solution may contain, for example, 0·5 g. of sodium-bismuth iodide, 7·5 g. of sodium iodide, and 1 g. of tartaric acid in 500 c.c. of water. The solutions have a strong germicidal action.—B. V. S.

Chloral and a phenol; Manufacture of a compound of ——. O. Hinsberg. G.P. 332,678, 15.4.17.

BY the interaction of chloral and *p*-acetaminophenol, with or without a solvent, chloral-acetaminophenol, $CH_3.CO.NH.C_6H_4.O.CH(OH).CCl_3$, is obtained. It forms a colourless and tasteless crystalline powder, m.p. about 160° C. When heated quickly it is decomposed with frothing and evolution of chloral vapour. Chloral is also liberated on boiling with water. The product acts as a soporific in smaller doses than chloral, and its action also differs appreciably from that of the latter.—C. A. C.

Glycol diacetate; Manufacture of ——. K. H. Meyer. G.P. 332,677, 29.7.19.

ETHYLENE DICHLORIDE and anhydrous sodium acetate are heated in presence of glycol diacetate. At 230° C. a smooth conversion takes place which would only be effected in a small degree without a solvent. Glycol diacetate, like the monoacetate, is a good solvent and gelatinising agent.—C. A. C.

Urea; Manufacture of —— from carbonic acid compounds of ammonia. Badische Anilin- und Soda-Fabr. G.P. 332,679, 11.7.15.

A "MELT" of ammonium carbamate, or of the product of the interaction of carbon dioxide and ammonia together with a small amount of water, is prepared in a separate vessel and is then forced under pressure into a reaction vessel. By making the reaction vessel part of a pressure-proof system the process may be made continuous. For example, a "melt" of 10 pts. of ammonium carbamate and 1 pt. of water, prepared at 60° C. under a pressure of 15 atm., is passed through a heated pressure-proof spiral pipe, heated at 135°—140° C. If the time occupied in passing through the spiral pipe is 2 to 3 hrs., then on relieving the pressure 25% of the carbamate will have been converted into urea. —C. A. C.

Urea melts obtained from carbon dioxide compounds of ammonia; Treatment of ——. Badische Anilin- und Soda-Fabr. G.P. 332,680, 11.7.15.

THE ammonium salts which have not been converted are distilled under pressure from the urea autoclave into another pressure-proof vessel at a lower temperature. The greater part of the ammonium carbamate and carbonate is easily and quickly precipitated in a solid or molten condition respectively. The pressure-proof receiver may either be a second urea autoclave or with advantage the vessel used for preparing the melt (*cf. supra*). The ammonium salts remaining in the urea autoclave are afterwards distilled off under normal or reduced pressure.—C. A. C.

Guanidine salts; Manufacture of ——. F. Hofwimmer. G.P. 332,681, 12.9.17.

ALKALINE-EARTH salts of cyanamide are heated together with ammonium salts to a suitable temperature; *e.g.*, calcium cyanamide is added to a melt of ammonium nitrate and then heated to 200°—220° C. The following reaction takes place: $CaCN_2+3NH_4NO_3 = C(NH)(NH_2)_2.HNO_3+Ca(NO_3)_2+2NH_3$. By solution, filtration, and crystallisation carbon, calcium nitrate, and guanidine nitrate are separated. The calcium nitrate remaining in the mother liquors is worked up to ammonium nitrate by means of the ammonia obtained.—C. A. C.

Aldehydes; Preparation of ——. K. W. Rosenmund. G.P. 333,154, 28.3.17.

ACID halides, or solutions of the same, are treated with hydrogen in the presence of a catalyst and a substance capable of combining with acid. Stearic aldehyde is prepared from a solution of stearic acid chloride in benzol in the presence of 5% of palladinised barium sulphate and calcium carbonate; benzaldehyde, *p*-hydroxybenzaldehyde, and butyraldehyde are prepared respectively from benzoyl bromide (or chloride), *p*-carbomethoxybenzoyl chloride, and butyryl chloride, using palladinised silicic acid as catalyst.—L. A. C.

Urea or ammonia; Production of —— from [calcium] cyanamide. S. Giertsen. E.P. 160,857, 14.8.19.

SEE U.S.P. 1,326,045 of 1919; J., 1920, 174 A.

Denitrating nitric esters. G.P. 333,708. *See* XXII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsion; Orientation of the grains in a dried ——. L. Silberstein. J. Opt. Soc. Amer., 1921, 5, 171—177.

A MATHEMATICAL analysis is given of the probable average orientation of silver halide grains in a sensitive film, making certain simple assumptions as to the nature of the drying process. It would appear highly probable that the "efficiency coefficient," *i.e.*, the ratio between the average projected area of the grain and its actual area, regarding all the grains as flat plates of small thickness, is very nearly unity in the dried film.—B. V. S.

[Photographic] reduction of developing-out papers; Sensitometric study of ——. L. A. Jones and C. E. Fawkes. J. Franklin Inst., 1921, 191, 503—516.

IN testing the effects of photographic reducers on developing-out papers, graded prints, obtained in the usual way by exposure in a non-intermittent sensitometer, and development, were measured by means of a reflectometer, then reduced, and again measured. A comparison of the curves obtained from these measurements shows both the extent and the nature of the reducing effect. Ten reducers were tested, full particulars being given of six of them, divided into 3 types. Potassium permanganate solution and Belitski's reducer (ferric chloride, sodium oxalate and thiosulphate) are of type 1, the contrast of the print being unaltered. Type 2, in which contrast is increased by reason of more vigorous action on the lower densities, includes iodine-cyanide and Farmer's (ferricyanide-thiosulphate) reducers. The third type, in which contrast is reduced, includes ammonium persulphate and the Nietz-Huse proportional reducer (permanganate-persulphate).—B. V. S.

PATENTS.

Colour photography. W. Friese-Greene, J. N. Thomson, and Colour Photography, Ltd. E.P. 160,540, 20.12.19 and 15.4.20.

A TONING solution, chiefly intended for production of the red constituent in two- or three-colour photo

graphy, contains potassium ferricyanide, uranium nitrate, Rose Bengale, Naphthol Yellow, and acetic acid along with iodine and/or Sensitol Red (Pinacyanol).—B. V. S.

Photographic developers. J. Hauff und Co. G.P. 327,111, 24.10.18, and 328,617, 10.12.18.

THE carboxylic and sulphonic acids of *o*- and *p*-aminophenol, of *o.p*-diaminophenol and of their homologues, *e.g.*, *p*-aminosalicylic acid, are used in caustic alkaline solution. The developers show no tendency to the formation of veil. The resulting silver image is brownish-black in colour.—B. V. S.

Photographic flash light; Production of ——. K. Hempel. G.P. 330,531, 15.10.19.

METALLIC aluminium and magnesium, together or singly, are mixed with manganite and/or permanganate of barium or mixtures of these, together with paraffin wax. Production of smoke is inconsiderable owing to the absence of potassium.

—H. J. H.

Photographic silver films; Intensifying ——. H. Franke. G.P. 333,094, 17.4.20.

BY the use of solutions of selenium compounds, such as a selenosulphate, selenium is deposited on the silver grains. It may be removed again by treatment with, *e.g.*, permanganate solution slightly acidified with hydrochloric acid.—B. V. S.

Coloured photographic pictures; Method and apparatus for producing ——. J. H. Christensen. U.S.P. 1,373,053, 29.3.21. Appl., 2.8.18.

SEE G.P. 313,836 of 1918; J., 1920, 45 A.

p-Aminophenol derivatives. E.P. 145,614 and 155,575-6. *See* XX.

XXII.—EXPLOSIVES; MATCHES.

Mercury fulminate; Characteristic reaction for the detection of ——. A. Langhans. Z. anal. Chem., 1921, **60**, 93—94.

IF mercury fulminate is moistened with alcohol, water added, and the mixture shaken with 20% sodium sulphantimonate solution, a yellow precipitate forms which gradually turns olive-green and then black. The filtrate from the precipitate gives a bright red colour with nitric acid; the colour is soluble in ether.—W. P. S.

PATENTS.

Nitroglycerin; Process for separating —— *from wash-waters.* Westfälisch-Anhaltische Sprengstoff A.-G. G.P. (A) 299,030, 5.11.15, and (B) 299,720, 5.2.16.

(A) BOTH suspended and dissolved nitroglycerin may be removed from the wash-waters by treating them with nitrocellulose. (B) Nitroglycerin is separated from a solution in aqueous acetone, containing up to 30% of acetone, by shaking the solution with, or filtering it through, nitrocellulose. The process should be conducted at a low temperature in order to minimise loss of acetone.—W. J. W.

Smokeless powders; Process for comminuting ——. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 332,284, 25.1.19.

POWDERS with a hard grain or surface are softened by means of gelatinising agents, or preferably, aqueous volatile solvents, and are then pulverised with addition of water in kneading machines.

—W. J. W.

Nitric acid esters of carbohydrates and glycerol; Process for completely or partially denitrating ——. H. Bucherer. G.P. 333,708, 14.12.18.

THE ester, *e.g.*, nitrocellulose, is mixed with or dissolved in sulphuric acid, and an aromatic compound, such as benzene, is added with vigorous agitation. The nitro groups migrate to the aromatic compound and the product settles into separate layers of benzene and sulphuric acid containing respectively nitrobenzene and cellulose in solution. Sulphonic acids or acid sulphates can be employed instead of sulphuric acid.—L. A. C.

XXIII.—ANALYSIS.

Melting points; Determination of —— [*especially of inorganic substances*]. [*Melting point of potassium chlorate.*] C. D. Carpenter. Chem. and Met. Eng., 1921, **24**, 569—571.

THE apparatus employed consists of a lagged beaker, with observation holes in the lagging, a platinum resistance thermometer, and a stirrer of which the speed can be adjusted. For the heating bath a mixture of potassium and sodium nitrates (m.p. 220° C.) is used. For temperatures above 600° C. both bath and melting point tube must be constructed of transparent quartz. In determining the melting point of potassium chlorate, the substance was melted and then cooled, and this process was repeated several times, the temperature being kept within narrow limits, and the crystals never being allowed to disappear completely. The temperatures at which new crystals formed on cooling were noted in terms of the resistance. By plotting the results on a graph, the resistance was found to be 116·435 ohms, corresponding to 357·10° C.

—W. J. W.

Sodium sulphantimoniate; Reactions of —— *with some metallic salts.* A. Langhans. Z. anal. Chem., 1921, **60**, 91—93.

THE coloration of the precipitates obtained when metallic salt solutions are treated with freshly-prepared sodium sulphantimonate solution is as follows: Iron, nickel, cobalt, and bismuth, black; aluminium, chromium, silver, copper, and lead, brown; manganese, orange; zinc and cadmium, yellow. Mercuric oxide is coloured black by the reagent, as are also mercuric oxalate and mercurous nitrate, whilst mercuric bromide is coloured yellow. Mercuric cyanide is at first coloured yellow and then black; mercuric chloride yields a reddish-yellow compound. Sodium stannate and arsenate do not give reactions. (*See also* Cl. XXII.)

—W. P. S.

Adsorption; Importance of —— *in analytical chemistry. IX. Glass wool as a filter material.* I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 463—471.

GLASS-WOOL should not be used for filtering warm dilute solutions of salts of metals or alkaloids, as considerable losses occur. (*Cf.* J.C.S., June.)

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Adams, Adams, and Linkie. Mixing-machines. 13,051. May 7.

Beldimano, Robertson, and Stanley. Evaporating or heating liquids. 13,082. May 7.

Blair, Campbell, and McLean, Ltd., and Wright. Apparatus for effecting intimate contact of liquids and gases. 13,004. May 6.

Buxton. Drying systems. 12,497. May 2.

Curtis and Jones. Drying apparatus. 13,045. May 7.

Evans (Allgem. Elektricitäts-Ges.). Apparatus for effecting perfect combustion of coal, coke, etc. in furnace plants. 12,394. Apr. 29.

Frischer. Apparatus for carrying out chemical and physical processes. 12,984. May 6.

Jewell. Stills. 12,220. Apr. 28.

Kenyon and Reynolds. Separating or grading powdered or granular materials, and treatment thereof by gases etc. 11,860. Apr. 25.

Paterson. Filtering-apparatus. 11,972. Apr. 26.

Pessi. Preventing incrustation in steam boilers. 12,981. May 6. (Ital., 6.5.20.)

Roberts. Grinding-mills. 11,876. Apr. 25.

Sklenar. Reverberatory furnace. 12,078. Apr. 27.

Thompson (Sharples Separator Co.). Centrifugal emulsifiers. 12,048. Apr. 27.

Thorne. 12,483. *See* IX.

Complete Specifications Accepted.

11,142 (1919). Miller, and Fletcher and Co. Filters. (161,993.) May 4.

22,661 (1919). Philip. Stills. (162,000.) May 4.

32,408 (1919). Patrick, Lovelace, and Miller. Separating and recovering gases. (137,284.) May 4.

2703 (1920). Meston. Separating suspended matter from liquids. (162,390.) May 11.

6962 (1920). Malkin. Grinding-mills. (162,481.) May 11.

7182 (1920). Soc. l'Air Liquide. Protection for walls of enclosures in which reactions take place at high temperatures and pressures. (140.083.) May 11.

9432 (1920). Holmes and Co., Henshaw, and Whittell. Apparatus for bringing liquids and gases into intimate contact. (162,166.) May 4.

10,852 (1920). Soc. des Condenseurs Delas. Cooling viscous liquids. (142,454.) May 4.

15,019 (1920). Rambaud. Evaporating and concentrating apparatus for syrups etc. (144,631.) May 11.

15,182 (1920). Petree. Apparatus for separating impurities in suspension from liquids. (162,206.) May 4.

20,214 (1920). Petzel. Separation of gas mixtures. (148,302.) May 11.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Amend. Refining petroleum distillates. 12,461. Apr. 30.

Bamber and Parker. Gas producers or generators. 12,789. May 4.

Bismarckhütte. Coking-chambers for generators. 12,974. May 6. (Ger., 6.5.20.)

Catton. Fuel. 12,951. May 6.

Clewlow. Disintegrating, dehydrating, etc. peat. 11,828. Apr. 25.

Duckham, and Woodall, Duckham, and Jones. Carbonising fuel in vertical retorts. 12,675. May 3.

Evans (Allgem. Elektricitäts Ges.). 12,394. *See* I.

Fournier. Manufacture of artificial fuel. 12,763. May 4. (Fr., 10.5.20.)

Jacobs. Drying lignite, peat, turf, etc. 12,911. May 5. (Ger., 27.5.20.)

Kirke. Water-gas plant. 12,889. May 5.

Kratochwill. Artificial fuel. 12,670. May 3.

Lloyd. Manufacture of coal etc. briquettes. 12,808. May 4.

Midland Coal Products, Ltd., Fisher, and Montgomery. Apparatus for distilling coal etc. 12,950. May 6.

Ricardo. Fuel for internal-combustion engines. 11,953. Apr. 26.

Salerni. Apparatus for distilling carbonaceous materials. 11,838. Apr. 25.

Soc. du Gaz de Paris. Manufacture of illuminating gas. 12,260. Apr. 28. (Fr., 18.5.20.)

Complete Specifications Accepted.

26,589 (1919). Pease. *See* VII.

32,165 (1919). Diver. Recovery of oil from bitumen, shale, etc. *in situ*. (162,337.) Apr. 11.

1512 (1920). Marr, and Coke Oven Construction Co. Coke ovens. (162,045.) May 4.

1576 (1920). International Coal Products Corp. Carbonising lignites. (142,443.) May 4.

1846 (1920). Hudson. Making decolorising carbon. (139,156.) May 4.

2316, 2320, 2322–4, 2326 (1920). American Coke and Chemical Co. Coke ovens etc. (138,124, 138,126, 138,128, 138,333–5.) May 11.

2333 (1920). Watchman Co., and Morris. Gas-generating apparatus. (162,085.) May 4.

3698 (1920). De Bruyn, Ltd., and Revis. Production of decolorising charcoal. (162,117.) May 4.

3863 (1920). Drakes, Ltd., and Drake. Vertical retort settings. (162,422.) May 11.

5247 (1920). Williams and Williams. Gas-producer. (162,455.) May 11.

5403 (1920). Nielsen and Garrow. Continuous production of solid and gaseous fuel with by-product recovery. (162,459.) May 11.

5666 (1920). Perry. Apparatus for distilling carbonaceous material. (162,136.) May 4.

8256 (1920). Bean. Producing gas. (162,159.) May 4.

14,106 (1920). Rambush. Removal of sulphur from gases. (162,554.) May 11.

24,471 (1920). Krupp A.-G. Separating slags containing iron from coke and other fuel residues. (152,642.) May 4.

29,412 (1920). Marr, and Coke Oven Construction Co. Coke ovens. (162,236.) May 4.

30,947 (1920). Gewerkschaft Emscher-Lippe, and Heyn. Coking-plants. (153,313.) May 11.

III.—TAR AND TAR PRODUCTS.

Applications.

Barrett Co. Manufacture of products of oxidation of aromatic hydrocarbons. 12,153. Apr. 27. (U.S., 18.6.20.)

Bismarckhütte. Separating water from coal tar. 12,974. May 6. (Ger., 6.5.20.)

Bradley, Glossop, and Willsdon. Distillation of tar etc. 12,524. May 2.

Commin. Treatment of pitch. 12,388. Apr. 29.

Complete Specification Accepted.

20,585 (1920). Sudfeldt u. Co. Obtaining salts of sulpho acids from lignite tar oils. (148,763.) May 11.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreyfus. Manufacture of cellulose derivatives. 11,854. Apr. 25.

Forster. Obtaining transparent effects on cotton fabrics. 12,463. Apr. 30. (Ger., 30.4.20.)

McRae. Treatment of bamboo, bagasse, etc. for extraction of cellulose. 12,919. May 5.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of cellulose compounds. 12,190. Apr. 28.

Soc. Pichard Frères. Process for carrotting hairs. 12,259. Apr. 28. (Fr., 15.5.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

24,519 (1919). White and White. Wool-washing machines. (162,313.) May 11.

2721 (1920). Great Northern Paper Co. Papermaking. (141,022.) May 4.

27,169 (1920). Great Northern Paper Co. Papermaking. (151,623.) May 4.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Crowther. Machines for treating textile fibres with liquids. 13,061. May 7.

Fergusson and Rhodes. Treatment and dyeing of woollen yarns etc. 12,713. May 4.

COMPLETE SPECIFICATION ACCEPTED.

13,731 (1920). Kershaw. Bleaching of fabrics. (162,198.) May 4.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Aluminium-Industrie A.-G. Manufacture of nitrate of calcium. 12,901. May 5. (Switz., 19.5.20.)

Boorman and Browning. 12,157. *See* XVI.

Brightmore. Fixation of atmospheric nitrogen. 12,146. Apr. 27.

Chem. Fabr. Griesheim-Elektron, and Suchy. Electrolytic production of potassium carbonate from potassium chloride solutions. 12,573. May 2.

Constant and Raisin. Production of boron. 11,947. Apr. 26. (Fr., 30.4.20.)

Heenan and Froude, Ltd., and Walker. Concentration of brine. 12,600. May 3.

Norris. Recovering sodium sulphate and a liquor of high acidity from nitre-cake. 13,029. May 7.

Parrish, and South Metropolitan Gas Co. Manufacture of neutral sulphate of ammonia. 12,116, Apr. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

17,624 (1917). Buchner. Production of aluminium hydroxide. (162,303.) May 11.

26,589 (1919). Pease. Extraction of ammonia from gases. (162,314.) May 11.

31,936 (1919). Field, and Metals Extraction Corp. Purification of zinc solutions. (162,030.) May 4.

1240 (1920). Ellis. *See* X.

2325 (1920). American Coke and Chemical Co. Ammonia saturators. (138,129.) May 11.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Stafford. Glass etc. furnaces. 11,893–4. Apr. 25.

Travers. Glass furnaces. 12,673. May 3.

COMPLETE SPECIFICATIONS ACCEPTED.

8949 (1920). Thompson. Annealing furnaces for glassware etc. (140,817.) May 11.

26,561 (1920). Harvey Gas Furnace Co., and Harvey. Furnaces for melting glass. (162,232.) May 4.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Briscoe and Faber. Rotary kilns for calcining Portland cement etc. 12,884. May 5.

Stoederum and Zondervan. Building material. 12,346. Apr. 29.

Tabary. Manufacture of material for buildings, roads, etc. 12,277. Apr. 28.

Thorne. Heat-conducting powder for covering boilers, pipes, etc., and for forming walls etc. 12,483. May 2.

COMPLETE SPECIFICATIONS ACCEPTED.

26,168 (1919). Fried. Production of building materials and artificial stones. (134,230.) May 11.

26,504 (1919). Dyring. Building material. (134,538.) May 11.

28,509 (1919). Bayer. Manufacture of stone-like materials of foam-like structure. (162,318.) May 11.

2080 (1920) Jones. Manufacture of disintegrated asbestos for use in making fireproof composition. (162,359.) May 11.

7389 (1920). Wallace. Treating clayey materials for making bricks, slabs, etc. (162,483.) May 11.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Akt. Ferrolegeringar. Manufacture of manganese alloys poor in carbon, or silicon, or manganese. 12,232. Apr. 28. (Sweden, 12.5.20.)

Akt. Ferrolegeringar. Production of chromium or its alloys. 12,233. Apr. 28. (Sweden, 12.5.20.)

Ashcroft. Precipitating precious metals from cyanide solutions. 12,347. Apr. 29.

Bansen, and Faconneisen-Walzwerk Mannstädt u. Co. Hearth smelting or heating furnaces. 12,793. May 4.

Blei- u. Silberhütte Braubach A.-G. Treating materials containing precious metals. 12,205. Apr. 28. (Ger., 12.8.20.)

Burgess. Reduction of aluminium oxide. 12,129. Apr. 27.

Hibbard. Metallurgical furnaces. 12,391. Apr. 29. (U.S., 1.11.19.)

Howse. Preserving steel or iron work against corrosion or rusting. 12,507. May 2.

Jones and Owen. Production of metallic dust. 13,018. May 6.

Koppers. Desulphurising large masses of iron and steel. 12,244. Apr. 28. (Ger., 28.4.20.)

Leon and Lister. Dyeing aluminium. 12,413. Apr. 30.

Patent-Treuhand Ges. Production of drawn tungsten wires. 13,010. May 6. (Ger., 7.5.20.)

Soc. Anon. Usines Métallurgique de la Basse-Loire. Production of basic steel. 12,260. Apr. 28. (Fr., 18.5.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

31,791 (1919). Elmore. Treatment of argentiferous lead-zinc sulphide ores. (162,026.) May 4.

31,936 (1919). Field and others. *See* VII.

1240 (1920). Ellis. Production of powdered metals and suboxides. (162,038.) May 4.

2433 (1920). Maguet. Reducing fused slag to a granular form. (162,375.) May 11.

2580 (1920). Rare Metals Reduction Co. Production of alloys. (138,348.) May 11.

2710 (1920). Fletcher. Electrodeposition of metals on iron and iron alloys. (162,391.) May 11.

5723 (1920). Bradbury, and Rolls-Royce, Ltd. Aluminium alloys. (162,467.) May 11.

18,964 (1920). Manuf. de Prod. Chim. du Nord Etabl. Kuhlmann. Removing dust from the gases derived from the roasting of ores. (147,020.) May 11.

24,471 (1920). Krupp A.-G. *See* II.

6912 (1921). Morgan Crucible Co., and Speirs. *See* XI.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Chem. Fabr. Griesheim-Elektron, and Suchy. 12,573. *See* VII.

Hart Accumulator Co., and Holmes. Secondary batteries. 12,703–4. May 3.
Niblett. Primary and secondary batteries. 11,911. Apr. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

21,585 (1919). Kreher. Electrodes for accumulators. (132,259.) May 11.
2710 (1920). Fletcher. *See* X.
16,726 (1920). Metallbank u. Metallurg. Ges., and Lilienfeld. Electrical gas purification (145,477.) May 11.
6912 (1921). Morgan Crucible Co., and Speirs. Electrically-heated melting and other furnaces. (162,246.) May 4.

XII.—FATS; OILS; WAXES.

APPLICATION.

Hildesheimer and Lion. 12,701. *See* XIX.

COMPLETE SPECIFICATIONS ACCEPTED.

25,932 (1919). Melamid and Grotzinger. Manufacture of products soluble in or forming emulsions with water. (134,223.) May 11.
2108 (1920). Schwarzkopf. Refining oils and fats. (138,115.) May 11.
2410 (1920). Bolton. Continuous hydrogenation of unsaturated oils, fats, etc. (162,370.) May 11.
2544 (1920). Bolton and Lush. Maintaining the activity of metallic catalysts during the hydrogenation of oils, fats, etc. (162,382.) May 11.
7059 (1920). Stiansen. Refining oils and fats. (141,028.) May 4.

I.—GENERAL; PLANT; MACHINERY.

Corrosion of boiler tubes by carbon dioxide; Unusual ——. B. G. Worth. Trans. Amer. Electrochem Soc., 1921, 329—335. [Advance copy.]

Severe corrosion of a water-tube boiler using natural water softened by a standard lime-soda process was found to be due to the presence of a soluble bicarbonate of iron, $H_2Fe(CO_3)_2$. The bicarbonate decomposed into ferric hydroxide and carbon dioxide on heating the water, and after the introduction of a preheater and the removal of liberated carbon dioxide before entering the boiler, corrosion practically ceased.—C. A. K.

Rust formation. E. Sauer. Chem.-Zeit., 1921, 45, 421.

Rapid corrosion of the condensed water outlet pipes of the radiators of a large drying plant was traced to the presence of carbonic acid in the boiler feed-water. When the feed-water was treated by the lime-soda process on the Breda system, thereby reducing the total hardness to about 3 degrees, and eliminating the carbonic acid, the corrosive action of the condensed water practically ceased.—G. F. M.

Patents.

Rectifying apparatus; Condensing arrangements of ——. E. Barbet et Fils et Cie. E.P. 138,869, 6.2.20. Conv., 8.2.19.

The cooling coils of the bubbling plates of a rectifying column as described in E.P. 13,599 of 1914 (F.P. 469,979 of 1913; J., 1915, 16) are fed with a portion of the rectified spirit from the combined condenser and cooler, and the rectified spirit thus preheated in the coils is admitted to the top of the column as the reflux fluid. This arrangement prevents formation of scale in the cooling tubes, and may also prevent it in the condenser, for there is no objection to using so large a quantity of condensing (and refrigerating) water that it never reaches the scale-forming temperature. The reflux rectified spirit instead of passing through the worms in the trays may, if desired, be passed through other tubes (or a plate) at the head of the column which will act as a preliminary condenser.—B. M. V.

Still-head; Spherical ——. O. Heublein and E. Weiler. G.P. 328,824, 23.7.19.

The spherical head is constituted of two spherical jackets, one inside the other, the intervening space being evacuated and the surfaces of the jackets silvered after the manner of a Thermos flask. A tube provided with a cruciform end placed within the spherical head allows of the passage of the vapours to the condenser, such vapours passing through the ends of the cross and through holes in the part of the tube just below the wall of the spherical head. The bottom side of the cross is inclined so that condensed liquid drains back into the distilling vessel.—J. S. G. T.

Distillation in vacuo; Plant for [continuous] fractional ——. E. Lühr. G.P. 332,001, 1.1.20.

The still can be connected in turn with any one of a number of condensers, each of which may be separately connected with evacuating apparatus and, after evacuation, shut off by a cock. The material to be distilled, *e.g.*, petroleum tar, is supplied from a vessel provided with cocks for shutting off connexion with both the atmosphere and the distillation vessel. The residue after distillation is run off into a vessel which may be evacuated.
—J. S. G. T.

Concentrated solutions [; Centrifugal apparatus for the] manufacture of ——. B. Junquera. E.P. 144,240, 9.8.19. Conv., 30.5.19.

The basket of a centrifugal apparatus has a double wall and double bottom, the cylindrical wall of the inner basket being perforated. The solid to be extracted is placed in the inner basket, and the solvent supplied through an axial opening to the space between the double walls. The centrifugal head of the liquid in the jacket space causes it to flow inwards through the solid matter, after which it may be exhausted over the rim of the outer basket or collected by a scoop and returned to the axial inlet of the same or another apparatus. The solid material may be preheated in a furnace and the extraction apparatus contained in a casing through which the hot gases from the furnace are passed.
—B. M. V.

Centrifugal pulp-thickener. J. T. Jaeger. U.S.P. 1,374,377, 12.4.21. Appl., 14.7.19.

The rotating member is tubular and flares to a larger diameter at the discharge end, where there are a non-rotating central outlet for the liquid and a peripheral outlet for the pulp.—B. M. V.

Grinding, crushing, and dividing granular substances; Apparatus for ——. V. Antoine. E.P. 147,686, 8.7.20. Conv., 14.7.17.

In a disc grinder the driven disc or millstone is mounted on a ball and socket joint on the end of the shaft, the grinding pressure is applied by a weight and lever, and adjustable stops are provided to limit the maximum and minimum grinding space.
—B. M. V.

Mills for grinding and disintegrating materials [; Classifying devices for conical ——]. H. W. Hardinge. E.P. 150,997, 20.8.20. Conv., 11.9.19.

A conical mill is provided with an additional classifying device consisting of a truncated conical hood surrounding and rotating with the outlet end of the mill which is perforated to allow partly ground material to pass out. The undersize flows away from the classifying hood either over the edge or through perforations. If the mill is mounted on tyres and rollers instead of a journal bearing, the hood may be entirely supplied through the ordinary outlet end of the mill. Alternatively, a baffle may be provided inside the mill proper at about the end of the cylindrical portion, this baffle being perforated with one large central hole and thus acting as a weir, or with many smaller ones and acting as a screen. In all cases a spiral conduit is provided to lead back the oversize from the classification compartment to the main portion of the mill.
—B. M. V.

Grinding mill. A. E. Jacobson. U.S.P. 1,374,207, 12.4.21. Appl., 7.4.19.

In a grinding machine with revolving beaters the grinding surface is formed from a segmental plate with loops cut and pressed out of it, the loops remaining attached by their ends.—B. M. V.

Asbestos cloth, more especially for the dry separation of solid matter from blast furnace gases and the like. E. Danhardt. E.P. 153,558, 9.7.20. Conv., 31.10.19.

Asbestos cloth is made with the warp or the woof composed entirely or partly of threads of loosely spun asbestos; the other threads are of metallic wires or tightly spun asbestos or both. After weaving the cloth may be roughened on both sides.
—B. M. V.

Furnaces for heating crucibles employed for melting or heating metals and/or other materials. The Crosthwaite Engineering and Furnace Co., Ltd., and J. W. Crosthwaite. E.P. 161,386, 11.2.20.

THE furnace is built up of a number of layers of refractory material which are each pierced with a large central round hole to accommodate the crucible and several other smaller holes (*e.g.*, one at each corner if the exterior shape is square). Each lamina has also fan-shaped recesses formed on each face so that when the laminæ are assembled with the outer or corner holes co-axial the pairs of fan-shaped recesses will form fan-shaped ports for the passage of air from the corner ducts to the central crucible chamber. The bottom of the crucible chamber is closed by a refractory hearth, and the whole rests on a hollow bed-plate through which air may be supplied to the vertical corner passages. The tops of the corner passages are closed by plugs so shaped that on rotating through part of a circle a flange will obstruct the upper fan-shaped ports.—B. M. V.

Fuller's earth; Method of preparing for transit insoluble materials such as ——. L. G. Hill. E.P. 161,419, 8.3.20.

DUSTY material, such as fuller's earth, is mixed with a dilute solution of sodium silicate, and after drying the product is broken into lumps. The material can be recovered in its original finely divided state by treatment with water.—B. M. V.

Filters. W. J. Still. E.P. 161,639, 5.1.20.

A BAG filter for large quantities of water carrying small quantities of solid has the framework for the bags constructed of strip metal on three sides and a cast base on the fourth, with coil springs stretched between the base and the further side. The cast base has outlet passages communicating with the interior of the springs, and several units may be clamped together to form a larger unit or block, the whole being enclosed in a pressure-tight casing to which the water is admitted under pressure. Two blocks of filters may be connected with a distributing valve which is automatically operated by rise of pressure (owing to clogging) to switch the liquid over to the other block of filters.—B. M. V.

Filtering material. E. Müller. U.S.P. 1,375,532, 19.4.21. Appl., 16.3.17.

THE ashes from vegetable matter, after treatment with a soluble silicate, are washed, dried, and powdered, and a plastic mixture of the product with powdered clay and water is moulded, dried, and baked at a glowing heat.—L. A. C.

Filter; Automatic ——. A. and A. Sommer. G.P. 330,078, 30.10.18. Conv., 19.2.14.

THE liquor flows upwards through a number of superimposed receivers separated by horizontal partitions. Each receiver is separated by the filter surface into an upper and lower chamber, and the inlet and outlet are situated respectively below and above the filter surface.—L. A. C.

Drying machine. T. Allsop and W. W. Sibson, Assrs. to The Philadelphia Drying Machinery Co. U.S.P. 1,374,709, 12.4.21. Appl., 18.12.19.

THE drying chamber contains a conveyor, *e.g.*, a zig-zag continuous chain with carriers for the goods, and a fan, which are driven from the same source of power but can be started and stopped independently; the direction of rotation of the fan may also be reversed.—B. M. V.

Drying materials; Process and apparatus for ——. E. M. Bassler. U.S.P. 1,374,874, 12.4.21. Appl., 24.3.16. Renewed 16.6.19.

THE material to be dried is carried forward on a suitable conveyor in a closed trunk, and meets a current of warmed air which is made to pass through the conveyor at intervals by baffle-plates.—B. V. S.

Drying liquids; Atomising process for ——. Chem. Verwertungsges. m.b.H. G.P. 332,000, 10.2.20.

THE liquid is delivered by a pipe to a trough, whence it overflows on to a plate, on the upper side of which it is subjected to a preliminary dispersion by a jet of fluid under pressure directed downwards upon the plate, prior to being atomised into the drying chamber by a similar jet directed upwards from beneath the plate.—J. S. G. T.

Evaporator. J. T. Wann, Assr. to R. C. Newell and W. C. Murdoch, jun. U.S.P. 1,375,431, 19.4.21. Appl., 4.5.20.

AN evaporator contains separate storing, heating, and exit chambers, and a drying chamber subdivided into a number of compartments in pairs for receiving the material on trays. Inlet flues on the one side of each of the compartments, and outlet flues on the other side, communicate with the heating and exit chambers respectively, and means are provided for deflecting the heat below each pair of compartments.—L. A. C.

Evaporation or concentration of solutions, emulsions, and suspensions, and for carrying out chemical reactions; Process and apparatus for ——. G. A. Krause. G.P. 329,658, 2.5.16.

THE liquid is delivered centrally to an atomising device consisting of a number of tubular arms attached to a chamber rotating with high velocity, the arms being provided with small openings for efflux of the liquid. The atomiser is contained within a chamber through which a current of air is induced, whereby the efficiency of its action is increased.—J. S. G. T.

Mixing liquids with gases or liquids, or gases with gases; Process and apparatus for ——. A. Wache. G.P. 323,655, 3.8.19.

THE respective fluids are forced under pressure from hollow members through fine jets tangentially into a mixing chamber, the respective discharges being in parallel planes one above the other and in counter directions. The fluid discharged through the lower system of jets ascends spirally in the mixing chamber and meets the oppositely directed stream of the other fluid, discharged from the upper system of jets, at the narrowest section of the mixing chamber, which tapers gradually.—J. S. G. T.

Filling material having the form of a truncated cone for reaction columns etc.; Annular ——. Stellawerk A.-G. G.P. 324,442, 14.11.17.

THE filling material is built up of rings in such manner that the inner and outer surfaces of the resulting structure have the form of truncated cones tapering in opposite directions. This form of packing takes up only about 35% of the space of the reaction chamber, compared with 40—60% taken up by other kinds of filling material.—J. S. G. T.

Saturated solutions; Apparatus for producing ——. W. Otte. G.P. 328,218, 8.11.19.

THE substance to be dissolved is supported in a series of superposed rings of inverted frusto-conical shape with their axes vertical, the diameter of successive rings increasing in the downward direction. The floor of the lowest ring upon which the substance rests is perforated for the passage of solvent. The device rests upon a down pipe, and is contained within a vessel holding the solvent, the top cone being above the level of the liquid.—J. S. G. T.

Heating or cooling device with scrapers. F. Fiedler, Dampfkesselfabrik, Maschinen- u. Apparate-Bauanstalt, O. Kittel, and F. Hornung. G.P. 328,761, 26.4.19.

A SERIES of cylindrical or hemi-cylindrical heating or cooling chambers is disposed with their axes parallel and adjacent to one another, and scrapers are arranged so as to remove any matter deposited upon the cylindrical surfaces, each scraper being effective over a half cylinder. A conveyor or similar device traversing the length of the apparatus and disposed above a channel serves for the removal and collection of material removed by the scrapers.
—J. S. G. T.

Steam boilers; Method of maintaining low pressure —— free from mud and scale. Maschinenbau-A.-G. Balcke. G.P. 331,279, 27.6.18.

SUFFICIENT hydrochloric acid is added to the feed water to convert carbonates into soluble chlorides; these salts are not decomposed at the comparatively low temperature, so that the water can be evaporated to 15% concentration without formation of scale or damage to the shell from free acid.—C. I.

Gases; Method of separating and recovering —— and apparatus therefor. W. A. Patrick, B. F. Lovelace, and E. B. Miller. E.P. 137,284, 24.12.19. Conv., 28.12.18.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Tar fog, dust, and water in producer gas; Determination of ——. E. Jenkner. Stahl u. Eisen, 1921, 41, 181—183.

IT is essential to cool hot gas before filtering to separate suspended matter, otherwise a fractionation of any deposited tar may occur. The gas is drawn at the rate of 60 l. per hr. through a glass tube 30 cm. long, one portion of which 10 cm. long and 2 cm diam., with a nozzle of 6 mm. diam., is water-cooled, and projects into the gas main. The after portion of the tube, 20 cm. long and 4 cm. diam., is packed with Raschig rings of glass, 5 mm. diam. These retain all the dust and practically all the tar. The residue is retained by a weighed glass tube packed with cotton wool. This is followed by two weighed U-tubes containing calcium chloride to retain water. To separate the tar and dust in the first tube, the tar is extracted with warm benzene, and the weight of dust retained by the Raschig rings is obtained. The benzene solution is filtered through a tared filter to obtain the weight of dust lost in the washing. The weight of tar can then be deduced.—H. J. H.

Petroleum residues; Method of determining the density of ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 148—150.

A SP. GR. bottle is weighed empty (p_1), a small piece of the petroleum residue is then pressed on the interior wall of the bottle and the latter again weighed (p_3); the bottle is then filled with water at 15° C. and again weighed (p_4). If p_2 is the weight of the bottle filled with water alone, then the sp. gr. (x) of the petroleum residue is given by the formula $x=(p_3-p_1)/\{p_2+p_3-(p_1+p_4)\}$.—W. P. S.

Petroleum; Refractive index of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 150—156.

THE refractive index of Roumanian petroleum increases with the boiling point of the fractions, the increase being greater than is the case with the specific gravity. The fraction, b.p. 50°—60° C., has $n^{15}_D=1{\cdot}384$ and sp. gr. 0·6830, whilst the fraction, b.p. 340°—350° C., has $n^{15}_D=1{\cdot}526$ and sp. gr. 0·9051.—W. P. S.

Petroleum; Optical rotation of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 181—188.

CERTAIN Roumanian petroleums, particularly the higher boiling fractions of these oils, contain optically active substances. As the colour of the fractions interferes with observation in the polariscope, even when the material is diluted with a solvent, the petroleum was filtered through fuller's earth under pressure before examination. Two oils examined in this way had $[\alpha]^{20}_D=+1{\cdot}19$ and $+1{\cdot}52$ respectively.—W. P. S.

Petroleum; Capillary constants of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 188—196.

THE capillary constant α, or the surface tension, is found from the formula $\alpha=d\times r(h+\frac{1}{3}r)/2$, where r is the radius of the capillary, d the sp. gr. of the petroleum, and h the height of the capillary column of oil. The value increases with the b.p. of the petroleum fraction; for the fraction, b.p. 50°—60° C., $\alpha=1{\cdot}92$, and for the fraction, b.p. 340°—350° C., $\alpha=3{\cdot}18$. The viscosity of the fractions increases more rapidly than does the capillary constant.
—W. P. S.

Light petroleum (pentane, hexane, heptane, octane); Narcotic action of ——. H. Fühner. Biochem. Zeits., 1921, **115**, 235—261.

In contradistinction to ether and to chloroform, the hydrocarbons mentioned when inhaled (by mice and rats) often cause great excitement, and soon affect the respiration adversely; benzene is an even more powerful excitant. In molecular quantities benzene is a somewhat less powerful anæsthetic than chloroform; ether has only one-quarter of its activity. Hexane and ether, heptane and benzene, octane and chloroform have about the same degree of activity. The activity in the homologous series, pentane, hexane, heptane, octane, increases approximately in the ratio $1:3:3^2$...... . The solubility in water diminishes in the same ratio.—G. B.

Blast-furnace gas. Fowles. *See* X.

Patents.

Coking retort-oven. J. Becker, Assr. to The Koppers Co. U.S.P. 1,374,546, 12.4.21. Appl., 8.11.20.

The coking chambers have contiguous heating walls with vertical combustion flues. Tapered horizontal flues in each heating wall connect a number of the combustion flues of their respective heating walls, the horizontal flues also communicating with the corresponding horizontal flues of an adjacent heating wall. Reversible regenerators, which can be regulated individually, extend crosswise parallel with the coking chamber and the heating walls, and are connected in pairs with combustion flues of a single heating wall. Means are provided for controlling the individual flow through individual regenerators and their connected groups of combustion flues.—A. G.

Constituents of the distillation gas from fuel [e.g., ethylene]; Process for the separate recovery of ——. F. Bergius and P. Kalnin. E.P. 146,332, 2.7.20. Conv., 26.10.17.

The gas is freed from tar, ammonia, and benzene, and is then passed over adsorbent charcoal at 0° to −20° C. The adsorbed gas is then expelled and again subjected to the same treatment. By repeated adsorption the ethylene content can be greatly increased, *e.g.*, from 1—2% successively to 17, 36, and 59%.—A. G.

Purifying coal gas; Method of —— *by means of ammonia.* C. Still. E.P. 147,583, 8.7.20. Conv., 10.12.17.

The scrubber first traversed by the cooled crude gas is sprayed with the highly concentrated final product of the ammonia-recovery plant, and the subsequent scrubber is sprayed with the weaker ammonia solution from the reflux condenser of this plant. The gas flows in series through further scrubbers which are traversed in counter current, first by condensed liquor from the crude gas which contains little ammonia, and then by fresh water for the purpose of completely or partially washing out the ammonia. The residue of ammonia remaining in the gas after passing the ammonia scrubbers is recovered, together with the ammoniacal vapours arising from the ammonia recovery plant, and containing hydrogen sulphide and carbon dioxide, in a saturating plant in the form of ammonium sulphate, for which the necessary sulphuric acid is produced from the hydrogen sulphide remaining in the exhaust gases from the saturator. When the whole of the ammonia is removed in the scrubbing plant the gas that leaves the recovery plant is washed with the ammoniacal liquor condensed in the preliminary cooling of the original crude gas, so as to return the ammonia carried by the first-named gas to the ammonia-recovery plant. —A. G.

Soot-carbon, retort-graphite and other carbon products; Process for the production of —— *from natural gas.* Rütgerswerke A.-G. E.P. 137,065, 24.12.19. Conv., 12.6.18.

Natural gas is decomposed to the extent of 65% only in a retort, and the exit gases are used for firing the retort. The degree of decomposition is regulated by varying the speed of the gas, which may be preheated by the exhaust from the combustion chamber.—C. I.

Petroleum jelly; Process for making a substitute for ——. Rütgerswerke-A.-G. E.P. 134,528, 1.10.19. Conv., 26.10.18.

Powdered pitch of m.p. about 50°—60° C., containing 50% or more of aliphatic hydrocarbons, produced, *e.g.*, by distilling low-temperature coal-tar, or lignite tar, at about 300° C., under reduced pressure, is treated below its softening point with petroleum ether and/or benzene, and/or other solvents, in sufficient quantity to yield a homogeneous, viscous mixture. The solvent is expelled after separation of the insoluble matter, yielding a product which, after purification and decolorisation by the usual means, can be employed as a substitute for petroleum jelly.—L. A. C.

Petroleum and analogous distillates; Process of cleaning and refining ——. A. J. Paris, jun. E.P. 161,253, 2.1.20.

The distillates are compressed in the form of spray, vapour, or mist, in the presence of a permanent gas free from oxygen and a neutral purifying liquid, such as glycerin, Turkey-red oil, mineral lubricating oil, or castor oil, under such conditions of temperature and pressure (which may range from 25 to 350 lb. per sq. in.) that cracking of the distillates is avoided. A mixture of the gas with oil vapour, prepared by treating the distillates or crude oil with the gas at a suitable temperature, may be fed into the compression chamber, or the gas and oil may be fed in independently. After the treatment the gas and purifying liquid are separated from the oil vapour, which is subsequently condensed, and are returned to the apparatus for treating more oil. —L. A. C.

Crude oil; Process of recovering ——. I. S. Joseph. U.S.P. 1,362,105, 14.12.20. Appl., 29.4.19.

To recover crude oil from emulsions, such as "cut oil," "bottom settlings," etc., the emulsion is subjected to centrifugal action so as to cause the constituents of different specific gravity to move along different paths, and a liquid of approximately the same specific gravity as the heavier constituent is introduced into the separator and caused to move along the path of the heavier constituent with a velocity greater than that of the latter, so as to carry along solid impurities which would otherwise be deposited.

[Air condenser for use in] apparatus for treating hydrocarbons. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,374,357, 12.4.21. Appl., 31.5.17.

A horizontal cylindrical vessel, fitted internally with horizontal tubes open at both ends, is separated into a number of chambers by baffles open alternately at the top and bottom to provide a sinuous path for the hydrocarbon vapours or the like which are led into the bottom of the vessel at a point near one end. A current of air, induced by connecting all the tubes, at the end near the inlet for hydrocarbon vapours, with a common flue, passes through the tubes and cools the vapours to progressively lower temperatures as they pass through the vessel, causing condensation of different fractions in the separate chambers, whence they are withdrawn.—L. A. C.

Petroleum-oils; Apparatus for distilling ——. A. D. Smith. U.S.P. 1,374,402, 12.4.21. Appl., 13.3.17.

A STILL consists of a vessel with a sloping bottom and a number of sloping tubes below the vessel connected at their ends with the bottom of the vessel, which is also connected with a well. The circulation of oil induced by heating the tubes and the vessel diminishes the deposition of carbon in the apparatus.—L. A. C.

Hydrocarbon oils; Process of converting higher-boiling-point —— into lower-boiling-point hydrocarbon oils. W. M. McComb. U.S.P. 1,374,858, 12.4.21. Appl., 3.7.20.

A MIXTURE of the oil with a smaller quantity of steam is passed through a coil heated at the inlet and outlet ends to the initial and final b.p. of the oil respectively, and at intermediate points to progressively higher temperatures increasing at the same rate as the b.p. temperatures of the oil increase in fractional distillation of a sample of the oil.—L. A. C.

Hydrocarbons; Process of distilling ——. W. C. Averill, jun. U.S.P. 1,375,245, 19.4.21. Appl., 12.7.19.

IN distilling crude petroleum oil containing material quantities of asphalt-forming material and having a high sulphur content, *e.g.*, Gulf Coast crude petroleum, to produce pale lubricating oil and distillates, including gasoline, a portion of the products of combustion employed for heating the still bottom is withdrawn from the flue, cooled, and passed through the oil in the still. The hydrocarbon vapours are subsequently condensed from the mixture of gas and vapour issuing from the still. —L. A. C.

[Mineral] oil; Apparatus for refining ——. S. F. Stephens, Assr. to W. J. Boyle, sen., and C. G. Grant. U.S.P. 1,375,427, 19.4.21. Appl., 14.11.18. Renewed 24.1.21.

THE oil is fed on to a rotating, horizontal plate within a still and flows as a thin film towards the periphery of the plate, whence it is discharged as a fine spray on to the walls of the still.—L. A. C.

Mineral oil hydrocarbons; Conversion of —— into low- and high-boiling products. Deutsche Erdöl A.-G., F. Seidenschnur, and C. Koettnitz. G.P. 302,585, 29.1.16.

THE oil is treated by one of the known cracking processes, and the benzine produced is removed from the products, which are then distilled to obtain a product having a boiling point and specific gravity near to that of the original oil. This is then put through the cracking process again, either alone or mixed with a proportion of the original oil. The process gives a larger yield of benzine which is free from the usual objectionable odour of benzine obtained by a cracking process, while the residue from the distillation is a more valuable lubricant than the usual tarry residue that is obtained, and a smaller quantity of gas is produced. The total loss in the process is about 8%.—A. R. P.

Lubricating-oil. R. H. Brownlee. U.S.P. 1,374,277, 12.4.21. Appl., 23.11.18.

THE oil produced as described in U.S.P. 1,309,432 (J., 1919, 621 A) has a flash point of 425°—450° F. (218°—232° C.), and a cold test of approximately −4° F. (−20° C.) for a cut having a viscosity of 76 at 212° F. (100° C.).—L. A. C.

Viscous [lubricating] oils; Manufacture of ——. Tetralin G.m.b.H. G.P. 333,060, 28.7.18. Addn. to 319,799 (J., 1920, 623 A).

FORMALDEHYDE, polymerisation products of formaldehyde, or substances capable of yielding formaldehyde, are allowed to react with hydronaphthalenes, with or without addition of condensing agents, but in absence of acids. By heating tetrahydronaphthalene with paraformaldehyde and phosphorus pentoxide a highly viscous oil (probably ditetrahydronaphthylmethane), b.p. 257°—258° C. at 15 mm., is formed, and also a brittle, light-coloured resin. If acids are used as condensing agents more resin is formed and the yield of oil is reduced. The viscous products may be used as lubricants, especially for refrigerating machines and aircraft engines. As the oils are easily sulphonated their sulphonic acid salts can be made use of for the manufacture of drilling oils and the like.—C. A. C.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Charcoal; Production of artificially dense —— [for gas-masks]. L. F. Hawley. J. Ind. Eng. Chem., 1921, 13, 301—302.

As a substitute for coconut shell for the manufacture of charcoal for gas-masks, the residue, obtained by hydrolysing sawdust with dilute acid and then leaching out the sugar, has proved to be more satisfactory as regards yield, density, and activity of the charcoal than any untreated wood. For small-scale experiments, 2-in. briquettes compressed at 35,000 lb. per sq. in. from 20-mesh sawdust, to a density of 1·21, were distilled in a 2·5-in. pipe, enclosed in a 4-in. pipe, pressure being maintained during the operation by means of a screw and falling weight. At about 300 lb. per sq. in. and a maximum temperature of 450° C., a 40% yield was obtained, the charcoal having an apparent density of 0·62 and a chloropicrin absorption value of 700 mins., as compared with 0·63 and 900, respectively, for coconut shell charcoal. The product was hard and shiny, resembled anthracite

coal, and had a conchoidal fracture. On a semi-commercial scale with a retort 10 ft. in length, the best results were obtained by slowly distilling 4-in. briquettes, made from 4- to 43-mesh dust, under pressures varying from 80 to 130 lb. per sq. in.; the product had an apparent density of 0·58 and a chloropicrin absorption value of 600. The less satisfactory results obtained on the large scale may be due to the vapours not escaping readily from the larger briquettes and to the coarser raw material used.—W. J. W.

Patents.

Retorts for the distillation of carbonaceous substances. Low Temperature Carbonisation, Ltd., M. Davidson, and H. L. Armstrong. E.P. 161,608, 14.10.19.

Coal or other carbonaceous substance is distilled at low temperature in relatively thin layers under such conditions that the gas and vapour evolved throughout the charge in the retort are rapidly drawn away from the hot retort walls, to which the heat is applied, into a central space or chamber, whence they are immediately withdrawn. This central space is capable of contraction to accommodate the expansion of the charge during distillation. In the case of vertical retorts, a collapsible casing or equivalent is used, and means are provided for permitting the inward movement of the plates constituting the collapsible casing. Steam may be admitted to the retort.—A. G.

Wood distillation. E. M. Sawtelle, Assr. to J. P. Carter and R. L. Squibb. U.S.P. 1,374,887, 12.4.21. Appl., 10.9.18.

Subdivided wood is fed continuously into a producer, air being blown in at the bottom, but no steam being injected. The products of distillation are led off into a condensation system from which the pyroligneous liquids are removed.—A. G.

Impregnated wood; Recovery of the preserving material from ——. H. Wiedemann. G.P. 334,307, 16.11.19.

Impregnated wood is subjected to fractional distillation whereby, in addition to the usual products of wood distillation, the substances, such as anthracene or creosote oils, or copper sulphate, which were used to preserve the wood, are also recovered. The distillation may be carried out in the usual way or, after addition of water, under increased pressure.—A. R. P.

Liquids of high organic content; Process of destructively decomposing —— and product of such process. A. H. White. U.S.P. 1,374,889, 12.4.21. Appl., 24.7.19.

An aqueous liquid, containing a large amount of organic matter and capable of yielding valuable carbon compounds upon destructive distillation, is intimately mixed, in a concentrated condition, with sufficient quicklime to heat the mass autogenously to a temperature at which destructive distillation occurs, and the volatile compounds are distilled off, at least the major portion of the heat required being supplied by the heat of the reaction. The residue is calcined to produce a fresh charge of lime. —A. G.

Electrodes for electric searchlights. Optische Anstalt C. P. Goerz A.-G. E.P. 148,450, 10.7.20. Conv., 24.9.18.

The formation of soot on electrodes used in searchlights which are operated on current overload is reduced by the addition of oxides or silicates, such as cerium oxide, silica, etc., to the electrodes. Alternatively, the electrodes may be surrounded with a casing of silicates.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Phenoxides; Decomposition of —— by heat. F. Fischer and U. Ehrhardt. Ges. Abhandl. Kennt. Kohle, 1919, 4, 237—263. Chem. Zentr., 1921, 92, I., 762—763.

Investigation of the products obtained by the dry distillation of a number of normal and basic metal phenoxides and cresyl-oxides showed that sodium and potassium phenoxides yield solely gaseous products, chiefly hydrogen and a little methane, whereas the compounds with other metals yield varying proportions of liquid products in addition to the above and other gases.—L. A. C.

Naphthalene; Exhaustive sulphonation of ——. H. E. Fierz and F. Schmid. Helv. Chim. Acta, 1921, 4, 381—387.

According to the results of Armstrong and Wynne (1885—1895), who showed that sulpho-groups never enter the naphthalene nucleus in the ortho-, para, or peri-position to one another, exhaustive sulphonation of naphthalene can lead to only two products, namely, the 1.3.6-trisulphonic and 1.3.5.7-tetrasulphonic acids. The authors are, indeed, unable to confirm the statement (G.P. 79,054) that these two acids are accompanied by Senhofer's naphthalenetetrasulphonic acid (Monatsh., 1882, 3, 112) when naphthalene is heated at 260° with concentrated sulphuric acid and phosphorus pentoxide. The apparent losses attending the manufacture of H-acid are dependent on the formation of the tetrasulphonic acid and on oxidative destruction of naphthalene. Together with the tetrasulphonic acid, the 2.7- and the 1.6-disulphonic acids are often formed in small proportions, these acids evidently undergoing further sulphonation to the 1.3.6-trisulphonic acid only with difficulty. 1-Nitronaphthalene-3.6.8-trisulphonic acid is described. (*Cf.* J.C.S., June.)—T. H. P.

Phenols of low-temperature tar. Gluud and Breuer. See XIII.

Lead compounds of phenols. Fischer and Ehrhardt. See XIII.

Patents.

Tar-oils, especially from lignite; Process for refining —— with aqueous alkalis. Deutsche Erdöl A.-G. G.P. 333,061, 24.10.18.

The oil is intimately mixed with the alkali solution by passing a current of steam through the two liquids. The mixture is then distilled with steam at temperatures up to 300° C. and eventually under reduced pressure. No separation of tarry and asphalt-like components takes place, and the distillate obtained is very pure and practically odourless.—A. R. P.

Pyridine bases; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 147,101, 7.7.20. Conv., 23.12.18. Addn. to 146,869 (J., 1921, 5 A).

Formaldehyde or acetone is substituted for a part of the paraldehyde. Thus, when 15 pts. of formaldehyde (30%) is heated with 8·7 pts. of ammonia (25%) and 13·2 pts. of paraldehyde a mixture of bases is obtained consisting of about 50% of aldehyde-collidine and 50% of methylpyridines, chiefly α-picoline. Ammonia, paraldehyde, and acetone give a product consisting almost entirely of trimethylpyridine. —G. F. M.

1.4-Naphthylenediamine and its sulphonic acids; Manufacture of arylsulphonyl and arylenedisulphonyl derivatives of ——. G. T. Morgan, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 160,853, 6.8.19.

ARYLSULPHONYL-1.4-NAPHTHYLENEDIAMINES, and arylenedisulphonyl-*bis*-1.4-naphthylenediamines, and the sulphonic acids of these compounds can be prepared by the reduction in a not too strongly acid or alkaline reducing medium of the *p*-azo derivatives of the corresponding arylsulphonyl- or arylenedisulphonyl-naphthylamines or their sulphonic acids containing the sulphonic group in the 2, 6, 7, or 8 positions. The reduction can be carried out with such reagents as zinc dust and sodium hydroxide, zinc dust and ammonium chloride, iron borings and dilute acids, alkaline sodium hydrosulphite, stannous or titanous chloride, etc., provided the medium is not sufficiently acid or alkaline to effect hydrolysis of the arylsulphonyl groups. Thus, for example, toluene-*p*-sulphonyl-1.4-naphthylenediamine is obtained by condensing α-naphthylamine with *p*-toluenesulphonic chloride in presence of sodium acetate, dissolving the product in sodium hydroxide, and treating with benzenediazonium chloride, whereby sodium benzene-4-azo-toluene-*p*-sulphonyl-α-naphthylamine separates; this is converted into the free azo compound, and the latter reduced with zinc and ammonium chloride in aqueous alcoholic solution. (*Cf.* J.C.S., June.)
—G. F. M.

Fluorene; Catalytic oxidation of ——. *Process of producing maleic acid. Process of producing anthraquinone. Catalytic oxidation of naphthalene.* (A) J. M. Weiss and C. R. Downs, (B, C, and D) C. R. Downs, Assrs. to The Barrett Co. U.S.P. 1,374,695, and 1,374,720-2, 12.4.21. Appl., (A) 21.11.19, (B and C) 3.7.20, and (D) 10.7.20.

(A) FLUORENE is oxidised to fluorenone by treatment at 300°—700° C. with a gas containing oxygen in the presence of a metallic oxide as catalyst. The use of mercury out of contact with the reaction mixture but in heat-transferring relationship thereto is claimed in the manufacture of (B) maleic acid and (C) anthraquinone by the partial oxidation of benzene and anthracene respectively by a gas containing oxygen in the presence of a catalyst. (D) Naphthalene vapour is partially oxidised by treatment with a gas containing oxygen in the presence of aluminium oxide as catalyst.—L. A. C.

β-Nitronaphthalene; Manufacture of ——. Tetralin G.m.b.H. G.P. 332,593, 7.10.19.

A MIXTURE of mononitrotetrahydronaphthalenes obtained according to G.P. 299,014 (J., 1920, 174 A) is subjected to fractional distillation; β-nitrotetrahydronaphthalene is separated from the first fractions by freezing and is dibrominated and the product distilled. By a vacuum distillation of the thick, oily, brominated product hydrobromic acid is split off at about 150° C. and β-nitronaphthalene, m.p. 76° C., distils over at 190°—200° C. at 20 mm. β-Nitronaphthalene cannot be obtained by direct nitration of naphthalene.—C. A. C.

1.4-Chloronitroanthraquinones; Manufacture of ——. F. Ullmann. G.P. 332,853, 17.8.16.

2.4-DINITRO-1-HYDROXYANTHRAQUINONE is treated with arylsulphochlorides in presence of substances capable of combining with acid. If the reaction is allowed to take place in presence of potash the hydroxyl group is replaced by chlorine and 1-chloro-2.4-dinitroanthraquinone is formed. If diethylaniline is used a good yield of 1.2-dichloro-4-nitroanthraquinone is obtained. 2.4-Dinitro-1-hydroxyanthraquinone, prepared from 1-hydroxyanthraquinone and nitric acid (sp. gr. 1·52) in sulphuric acid solution, forms yellow needles (from glacial acetic acid), m.p. 248° C.; it is slightly soluble in hot alcohol and hot glacial acetic acid, easily soluble in nitrobenzene. 1-Chloro-2.4-dinitroanthraquinone crystallises from glacial acetic acid in slightly yellow needles, m.p. 240° C., slightly soluble in hot alcohol, soluble in benzene, easily soluble in nitrobenzene; by heating with β-naphthylamine in amyl alcohol solution the purple compound 2.4-dinitro-1-β-naphthylaminoanthraquinone is obtained. 2.4-Dinitro-1-hydroxyanthraquinone heated with *p*-toluenesulphochloride and diethylaniline gives 1.2-dichloro-4-nitroanthraquinone, yellow needles from benzene, m.p. 246° C., slightly soluble in alcohol, soluble in benzene, easily soluble in nitrobenzene.—C. A. C.

Liquors containing phenoloid bodies; Purification of ——. The Koppers Co., Assces. of C. A. Basore. E.P. 139,168, 14.2.20. Conv., 15.2.19.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool; Harmful action of acids on ——. M. Becke. Textilber., 1921, 2, 194—195.

WHEN treated with acids wool acquires an acidic character so that its resistance to treatment with alkalis is diminished. When samples of wool were steeped for 2 hrs. in solutions containing respectively hydrochloric, sulphuric, oxalic, formic, and

acetic acids, 0·9, 0·4, 0·4, 0·225, and 0·1% of the wool dissolved. The same samples were washed, dried overnight, neutralised with a very dilute solution of sodium bicarbonate, and boiled for 2 hrs. in a 4% (on weight of wool) solution of Marseilles soap, whereby a further 1·8, 2·0, 1·35, 1·15, and 1·0% of the wool dissolved. When different samples of wool were immersed for 2 hrs. in solutions containing 0, 2, 4, 6, 8, and 10% respectively of sulphuric acid, whereby 0·35, 0·20, 0·45, 0·75, 1·10, and 1·50% of the wool dissolved, and were then washed, neutralised in a dilute solution of sodium bicarbonate, and heated for 2 hrs. at 95°—100° C. in a solution containing 2·5% of sodium carbonate, a further 1·2, 1·8, 3·0, 4·4, 5·2, and 7·6% of the wool dissolved. When samples of wool, after immersion in solutions containing 4% of sulphuric acid and 0, 10, 25, 50, 100, and 200% of Glauber's salt, whereby 0·45, 0·375, 0·35, 0·30, 0·275, and 0·20% of the wool dissolved, were treated with a 4% solution of soap at 95°—100° C., a further 2·0—1·9% of the wool dissolved. Under the same conditions, except that acetic acid (5% instead of 4%) and sodium acetate were used in place of sulphuric acid and Glauber salt, 0·10, 0·125, 0·20, 0·24, 0·25, and 0·25% of the wool dissolved, and in the subsequent soaping the amount of wool which dissolved was 1·20—1·30%.—A. J. H.

Retting; Investigations of the process of ——. E. Kayser and H. Delaval. Bull. Soc. d'Encour., 1920, 132, 277—296.

THE conditions affecting the retting of fibrous materials such as flax, hemp, ramie, jute, and nettles by means of six different kinds of microorganisms isolated from macerations of flax, hemp, jute, etc., have been investigated; all of the microorganisms were aërobic except one, which was a facultative anaërobe. Sterilisation of the materials before retting was effected by means of alkali hypochlorite solution or preferably with carbon bisulphide vapour. The optimum temperature for four of the organisms used was 25°—30° C., and for the others 32°—35° C. Manganese salts hindered retting, and aeration of the retting liquors was beneficial in one instance and detrimental in another. In one experiment the gas liberated in the early stages of retting contained 65% of carbon dioxide and 35% of nitrogen, and in the later stages it contained 75% and 25% respectively, while the retting liquor contained alcohol and a much smaller amount of acetic acid. By the selection of suitable bacilli and conditions the retting process may be scientifically controlled so as to give uniform results.—A. J. H.

Reeds (Phragmites communis, Trin.); Composition of ——. F. Herig. Cellulosechem., 1921, 2, 25—34. (*Cf.* Heuser, J., 1920, 744 A.)

IN an investigation of the composition of reeds (*Phragmites communis*), the cellulose content was determined by the chlorination method of Cross and Bevan (an improved form of apparatus is described), the pentosans by Tollens' furfural method, moisture by drying at 105° C., ash by carbonisation with ammonium nitrate, and the lignin content by difference. In different samples of air-dried reeds the stems (57·09—60·92% of the total), sheaths (16·35—16·38%), and leaves (26·56—22·70%) contained respectively: cellulose, 38·64—40·98, 24·96—31·06, and 21·45—21·35%; pentosan, 17·27—19·66, 15·75—17·59, and 15·21—10·52%; lignin, 32·42—30·36, 37·42—35·35, and 42·01—50·79%; ash, 2·20—2·00, 14·00—8·00, and 11·33—10·67%; moisture, 9·47—7·00, 7·87—8·00, and 10·00—6·67%.—A. J. H.

Swelling [of cellulose acetate]; Nature of the process of ——. E. Knoevenagel and O. Eberstadt. Kolloid-Chem. Beih., 1921, 13, 194—212.

CELLULOSE acetate does not swell in pure water or in absolute alcohol, but it will swell readily in aqueous mixtures of alcohol, acetone, and acetic acid. In each case there is a definite mixture where the swelling is at a maximum. Unswollen cellulose acetate is only slowly dyed at 25° C. by a 0·05% aqueous solution of Methylene Blue, and the maximum coloration is reached only after several months. Under identical conditions swollen cellulose acetate is dyed to the maximum tint in a few minutes. Unswollen cellulose acetate is hydrolysed by aqueous alkali hydroxide solutions with the greatest difficulty, but the swollen material is completely hydrolysed in 30 mins. by a $N/2$ solution of potassium hydroxide at 25° C. (*Cf.* J.C.S., June.) —J. F. S.

Sulphite liquors; Titration of ——. R. Sieber. Paper, Apr. 6, 1921, 24—27.

RESULTS are given of a comparative investigation of methods for analysing sulphite liquors, and the high values (5—15%) obtained for the free acid when determined by titration with standard alkalis are shown to be due to carbon dioxide. For works practice the total acid is most suitably determined by means of the iodometric method. Sander's new method (J., 1921, 256 A) which depends on the reaction between bisulphite compounds and an excess of mercuric chloride, whereby hydrochloric acid is liberated, gives correct results only when carefully carried out and is therefore more suitable for laboratory control and for exhaustive investigations. The free acid is most conveniently determined by Sander's older method or by Höhn's method. This latter gives more accurate results (maximum error 1—2%) if methyl orange or p-nitrophenol be used as an indicator, instead of phenolphthalein.—A. J. H.

Sulphite-pulp; Determination of the degree of digestion of ——. R. Sieber. Paper, Apr. 6, 1921, 17—22.

THE degree of digestion of sulphite pulp may be estimated by means of a solution of bleaching powder. 21 g. of moist pulp (5 g. of dry pulp) is placed in a brown glass bottle (light appreciably affects the reaction) with 150 c.c. of distilled water and is allowed to stand for ½ hr. in the case of a dry pulp. 100 c.c of a solution of bleaching powder containing 6% (on weight of pulp) of active chlorine is added, and after 1 hr. the mixture is filtered through a bronze sieve and the remaining chlorine is determined in 50 c.c. of the filtrate. The amount of chlorine absorbed by the pulp ("chlorine number") is proportional to its lignin content and is related to the quality of the pulp as judged by its physical properties. The results obtained by this method with hard and soft pulps are similar to those obtained by the methods of Klason (J., 1911, 79), Richter (J., 1912, 869), and Becker (J., 1920, 482 A). The chlorine numbers of 25 pulps varied from 2·7 to 8·5, but were found to be somewhat too high in the case of very completely digested pulps. The chlorine number is influenced by the poor washing of a pulp, but this may be avoided by washing the pulp with 150 c.c. of warm water for ½ hr.—A. J. H.

Paper pulp; Dyeing of ——. J. Huebner. J. Soc. Dyers and Col., 1921, 37, 139—145.

IN the manufacture of paper pulp the degree of disintegration of the fibres produced by beating greatly influences the affinity of the pulp for dyestuffs. When samples of pulp produced from purified cotton yarn were immersed under comparable conditions in a solution of Night Blue the amount of dyestuff absorbed was inversely proportional to the average length of the fibres, and while unbeaten cotton yarn showed a constantly increasing absorption during 72 hrs., the absorption by the most highly disin-

tegrated pulp was almost complete during the first hour. The highly disintegrated pulp absorbed twice as much dyestuff as the unbeaten yarn, but had no greater depth of shade. In the case of pulp made from wool, increased disintegration augmented the rate of absorption but did not influence the amount of dyestuff absorbed. When immersed in a solution of Night Blue, jute, bleached poplar cellulose, and unbleached sulphite-cellulose absorbed the dye more quickly than bleached esparto cellulose and cotton half-stuff. Purification of sulphite-cellulose reduced its affinity for the dyestuff. The sizing of paper greatly increases its affinity for dyestuffs, and when resin size was added to a dye-bath containing Metanil Yellow or Scarlet R and alum, the pulp immersed therein rapidly absorbed 80—90% of the dyestuff. For the production of cheaper and faster shades, such mineral colours as Iron Buff, Chrome Yellow, Manganese Bronze, and Prussian Blue should be precipitated within the pulp. Acid dyestuffs have small affinity for paper unless it is heavily sized. Fast shades are obtained by precipitating an acid dyestuff by means of a basic dyestuff within paper pulp, and useful combinations are Auramine and Naphthol Yellow S; Chrysoidine, Magenta, or Brilliant Green and Orange II.; Victoria Blue and Water Blue or Methylene Blue, Rhodamine and Eosin, etc. Direct dyes are especially suitable for the production of mottled paper, and the shades obtained are fast.—A. J. H.

Straw pulp for the manufacture of cardboard; Colouring ——. H. Press. Papierfabr., 1921, **19**, 261—266, 365—368.

THE possible production of coloured cardboard by the direct addition of mineral or organic colouring matters to the straw pulp in the hollander was investigated. The dried straw pulp (after previous boiling with milk of lime under 4—5 atm. pressure) contained cellulose 40·4%, pentosans 20·5%, lignin (by diff.) 29·9%, and ash 9·2%. The mineral matter consisted chiefly of calcium silicate, $CaSiO_3$, and this was not removed in the preparatory treatment of the pulp. A solution of the dyestuff was added to a known weight of pulp, and after 20 mins. the exhausted dye solution was poured into a glass cylinder and its colour matched by the addition of a standard solution of the dye to water (which had been poured off from undyed straw pulp) contained in another cylinder. Straw pulp absorbed 95% (of the dyestuff added) of direct cotton dyes, 78—93% of basic dyes, and 53—75% of acid dyestuffs. The absorption of mineral colouring matters was determined by means of ash estimations and varied from 17 to 54%. For the production of a khaki-coloured cardboard a mixture of a mineral and an organic colouring matter was found to be suitable.—A. J. H.

Paper; Investigations of materials suggested for the manufacture of ——. Bull. Imp. Inst., 1920, 18, 323—335.

STEMS of *Cyperus Papyrus* from Egypt treated with caustic soda under conditions similar to those used for the preparation of paper pulp gave 34—42% of dry pulp, which was difficult to bleach and was unsuitable for the production of white paper. Samples of Bourdie grass (*Typha* sp.) from Egypt gave about 35% of dry pulp, which was difficult to bleach, and produced a harsh, stiff paper, which shrunk considerably in drying. The Kokerboom (*Aloe dichotoma*) from South Africa is not a suitable paper-making material, and is inferior to other South African products. Vau stems (*Hibiscus tiliaceus*) from Fiji gave a good yield of pulp, but of inferior quality. Matai wood (*Podocarpus spicatus*) from New Zealand gave a very low yield of pulp, which was not suitable as a paper-making material. "Tabocca Brava," a bamboo from Brazil, furnished, on rather drastic treatment, a good yield of pulp of fairly high quality, suitable for wrapping papers. Aninga (*Montrichardia arborescens*) stems from Brazil yielded a pulp furnishing a good brown paper, but the pulp could not be bleached sufficiently for the manufacture of paper suitable for writing or printing purposes.—J. PATENTS.

Pressed [fibrous] material; Manufacture of articles from ——. Ottmar Reich, and H. Weiss. E.P., 133,952, 13.10.19. Conv., 23.3.17.

DRIED straw and similar reed-like materials are disintegrated, treated with dilute solutions of alkalis (*e.g.*, 0·5% of caustic soda), acids (*e.g.*, 0·42% of nitric acid), or sulphites, whereby ligneous incrusting substances are removed, and are then bleached. Successive treatments of the raw material with caustic soda and a hypochlorite give better results than when both substances are used together. The moist pulp so obtained is "formed" under pressure in moulds made of porous material, which allow excess of water to be expressed.—A. J. H.

Balloon envelope material and process of manufacturing same. Ballonhüllen Ges. E.P. (A) 139,795 and (B) 139,807, 3.3 and 4.3.20. Conv., 3.3.16 and 22.9.17.

(A) GAS-TIGHT balloon fabric is built up of a textile fabric united to an animal entrail skin, such as goldbeater's skin, by means of an adhesive layer containing glue and a substance to render it elastic. A suitable adhesive composition consists of 100 pts. of water, 10 pts. of gelatin, 10 pts. of Turkey-red oil, and 5 pts. of glycerin; 0·25 pt. (or 1%) of potassium bichromate or formaldehyde is added for waterproofing purposes. (B) The goldbeater's skin may be dispensed with if the textile fabric is coated with several layers of the adhesive composition. (Reference is directed in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 12,230 of 1890; J., 1891, 1016.) —A. J. H.

Degumming textile materials. Soc. Suisse de Ferments. E.P. 145,583, 29.6.20. Conv., 30.6.19. (*Cf.* Tagliani, J., 1921, 256 A.)

THE rapid loss of diastatic power which occurs when a dilute solution of animal amylase (obtained from slaughterhouse waste) is heated at 55°—60° C., is greatly diminished by the addition of neutral salts (notably chlorides) of alkali or alkaline-earth metals. Sodium chloride and calcium chloride are suitable, 3—5 kg. being used per 1000 l. of solution. Textile materials are more easily penetrated by the solution of amylase if it contains a biliary salt such as is present in pancreatic juice and purified ox gall. —A. J. H.

[Textile] fibres; Process and apparatus for degumming and washing ——. R. L. Pritchard. E.P. 161,219, 7.11.19.

FIBRES are packed in receptacles (7—15 cm. deep) having solid lateral walls and perforated bottoms, which are piled one above the other (the top one having a perforated cover) and secured so as to form a rigid column. This is fitted tightly within a vessel open at both ends and standing on a perforated shelf which rests on the bottom of a larger vessel containing the liquid used for treating the fibres. The liquid rises upwards through the fibre receptacles and is pumped back into the outer vessel. The fibres are thus subjected to a continuous unidirectional flow of liquor, whereby adhering

matters are loosened. The pile of fibre receptacles is then removed and made to slide slowly down through a vessel containing pure water, whereby the fibres are washed free from the loosened impurities. —A. J. H.

Retting of fibrous straw; Method of and bath for ——. J. M. Masson. U.S.P. 1,374,941, 19.4.21. Appl., 12.1.20.

Straw is steeped and then boiled in a solution containing trisodium phosphate and sulphonated oils, and is then washed.—A. J. H.

Viscose silk; Manufacture of artificial ——. E. Bronnert. U.S.P. 1,374,718, 12.4.21. Appl., 8.9.20.

Artificial silk thread up to 1 denier in fineness is produced by spinning raw viscose, containing alkaline condensation products of phenols and aldehydes, in a bath containing a bisulphite, the concentration of which is inversely proportional to the fineness of the thread.—A. J. H.

Cellulose; Manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 331,950, 13.1.18.

Wood, straw, or the like is treated with alkali and carbon dioxide. The treatments may take place once or several times, and in any succession. If ammonia is used as alkali it can be recovered as well as the carbon dioxide. After the aqueous liquors have been separated from the cellulose they can be concentrated in order to convert them into a fodder which, like molasses, is mixed with bran, peat, and the like.—C. A. C.

Paper in pulp form; Sizing of ——. J. W. Zanders. G.P. 303,341, 20.9.16.

Montan wax is saponified with caustic alkali, especially with potassium hydroxide, and is converted into a stable emulsion. The emulsion is added to the pulp in the hollander, and the montan wax is precipitated by aluminium salts or the like and fixed in the paper fibre. By sizing further than to the standard hardness a dense watertight paper is obtained without special impregnation.—C. A. C.

Paper; Method for sizing —— with animal glue or proteins. F. Hassler. G.P. 331,350, 31.3.14.

The precipitation of the glue and proteins is effected by means of sulphonic acids of unsaturated hydrocarbons, especially of the higher hydrocarbons of coal tar, or by condensation products of the sulphonic acids obtained by heating a mixture of them, or by condensing them with formaldehyde or with phenolsulphonic acids. As the precipitates may be easily obtained pure white and are not coloured by iron salts, they may be applied to all pulp products. The pulp is treated either alternately with the glue or protein solutions (the latter from yeast or fish) and the solutions of the precipitating agents, or glue (protein) and precipitant are added together dissolved in sodium carbonate; precipitation takes place when acid or aluminium sulphate is added. For surface sizing the paper is passed first through a solution of the condensation product and then through a solution of glue and afterwards is dried as usual. Examples of the application of the condensation products prepared from naphthalenesulphonic acid alone or with formaldehyde or phenolsulphonic acid are given.—C. A. C.

Paper and pulp products; Method for sizing and impregnating ——. H. T. Böhme, A.-G. G.P. 331,742, 16.5.18.

Sulphite-cellulose waste lyes are applied together with emulsions of coumarone-resin and animal glue, or coumarone-resin and crude montan wax, or crude montan wax, or crude "montan wax colloid." Even when neutralised the sulphite lye acts as a precipitant for the above emulsions and participates in the sizing. For the precipitation of strongly alkaline emulsions acid sulphite-cellulose lye is used, or if the light-coloured neutral waste lye is used, other acid precipitants, as aluminium sulphate or dilute acids, are added. When precipitating emulsions of coumarone-resin and animal glue by sulphite lye the greater part of the glue is also precipitated. For the manufacture of waterproof paper or pulp products the dyed material is first treated with sulphite-cellulose lye, which may have to be acidified, and then is treated with the emulsions. The two-bath system may also be used with advantage for other textile products.—C. A. C.

Furnace plant for the recovery of salts, especially in sodium sulphate cellulose factories. W. Schacht. G.P. 317,082, 11.10.18.

A calcining and melting furnace mounted to rotate on wheels, rollers, or ball bearings, is movable parallel and perpendicular to the longitudinal axis of a rotary furnace, and the discharge outlet of the latter is faced with refractory material and adapted to fit into the inlet of the melting furnace, so as to make an almost air-tight junction for the transfer of material from the rotary furnace to the hearth of the melting furnace.—J. H. L.

Sulphate-cellulose plants; Treatment of gases and vapours from ——. A. E. Nielsen. G.P. 333,031, 6.3.19. Conv., 13.10 and 15.12.17.

The gases are treated with an absorption mass containing calcium carbonate. The green waste lime from the manufacture of sulphate-cellulose may be used with advantage. After the treatment with the gases the mass contains: sodium carbonate, sodium sulphide, sodium sulphate, sodium thiosulphate, hydrogen sulphide, thiocyanic acid esters, sodium thiocyanate, acetone, other ketones, aldehydes and mercaptans, calcium sulphite, calcium sulphate, calcium sulphide, calcium oxide, calcium tetrathionate, calcium carbide, etc., which can be converted into useful products. Calcium thiosulphate is converted into sodium thiosulphate.—C. A. C.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Woollen fabrics; Two- and multi-coloured effects in ——. M. König. Textilber., 1921, 2, 178.

COLOURED effects may be obtained in the piece-dyeing of woollen fabrics by suitably treating part of the yarn before weaving. Yarn which has been treated with chlorine or caustic soda has an increased affinity for acid, mordant, and direct cotton dyes, and yarn mordanted with tannic acid and tin or antimony salts loses its affinity for acid wool dyes but is strongly coloured by basic dyestuffs. After treatment with solutions of potassium, ammonium, or calcium thiocyanate, wool has a permanently increased affinity for acid, afterchrome, and mordant dyestuffs. Wool which has been immersed for 1—1½ hrs. at 50° C. in a solution containing 25% of sodium thiosulphate and 16% (on weight of wool) of hydrochloric acid of 22° B. (sp. gr. 1·18) has a diminished affinity for acid, substantive, and mordant dyes, and an increased affinity for basic and vat dyestuffs.—A. J. H.

Dyeing of wool; Direct ——. L. Guglialmelli and C. G. Estrella. Anal. Soc. Quím. Argentina, 1920, 8, 325—326.

WOOL and silk can be dyed directly by diazotisation and subsequent treatment with certain polyphenols and phenolic glucosides. By the use of metallic salts, such as potassium bichromate and copper sulphate, variations in shade and greater fastness to light can be obtained.—G. W. R.

[Printing] reserves under Indigo; Function of manganese oxide in ——. R. Haller. Textilber., 1921, 2, 173—174.

THE conditions under which manganese compounds may resist the fixation of vat dyestuffs on fabrics have been investigated by means of a Schleicher-Schull dialysing cell, the material of which has been considered as having the properties of a cotton fibre. The dialyser was filled with a solution of manganese chloride and placed in a 2% solution of caustic soda. After 24 hrs. the inner liquid was clear and neutral, but a precipitate of manganese hydroxide had formed in the caustic soda solution. A cross-section of the thoroughly washed dialyser showed that a brown deposit of manganese hydroxide had formed on the outer half of the membrane, while the inner half was free from manganese. When a solution of indigo reduced by means of hydrosulphite was dialysed in the same dialyser, which was immersed in water, the indigo penetrated considerably into the deposit of manganese hydroxide. In another experiment, the dialyser (immersed in 2% caustic soda) contained a solution of 20 pts. of manganese chloride and 1 pt. of sodium bichromate, and after 24 hrs., no bichromate remained in the inner solution. A cross-section of the dialyser showed (inside to outside), a brown deposit of a manganese-chromium compound, a colourless layer, another brown manganese-chromium deposit, a broad colourless layer, and a small deposit of manganese hydroxide. These facts are attributed to the formation of a compound, $2MnO_2,Cr_2O_3$, which has been prepared, and is regarded as an adsorption compound of a manganese chromate with manganite. When the same dialyser was used for the dialysis of a solution of indigo and hydrosulphite, the indigo only penetrated as far as the first manganese-chromium deposit. It is concluded that indigo reserve pastes which contain manganese chloride and sodium bichromate are effective because of the high oxidising power of the manganese chromate which is formed, and that for this type of reserve indigo vats prepared with zinc and lime are more suitable than those containing hydrosulphite, since the latter diffuse more quickly through the dialysing membrane.—A. J. H.

Ultramarine; Printing fabrics with ——. G. Stein. Textilber., 1921, 2, 176—177.

IT is difficult to obtain effects which are fast to washing by means of printing pastes which contain starch and coarse varieties of ultramarine, since the affinity of ultramarine for cotton decreases with an increase in the size of the ultramarine particles. Moreover, in order to avoid "scumming," it is necessary to add to the printing paste such substances as dextrin, gums, and caustic soda, and these decrease the affinity of ultramarine for the fibre.—A. J. H.

PATENTS.

Bleaching of fabrics. J. Kershaw. E.P. 162,198, 19.5.20.

WOOL, cotton, silk, and other fabrics in piece form are passed through a bath containing a cold 25% solution of hydrogen peroxide made slightly alkaline with ammonia, and after a period (16 hrs. for medium weight woollens) are washed with soap, and then passed through a cold 8½% solution of sodium hydrosulphite (a trace of sulphuric acid may sometimes be added), washed, and dried. The bleaching effect is permanent and the baths may be used continuously.—A. J. H.

Dyeing with acid sulpho-amino dyestuffs; Process for ——, *and manufacture of lakes.* Farbenfabr. vorm. F. Bayer und Co. E.P. 143,242, 12.5.20. Conv., 31.10.14.

DYEINGS and lakes produced from acid dyestuffs which contain both sulpho- and amino-groups are rendered faster to light by treatment with a complex metatungstic acid or its salt. Phospho-tungstic, silico-tungstic, and antimony-tungstic acids are suitable. In wool dyeing, 1% of the tungstic acid is added to the dye-bath before or towards the end of the dyeing process. In the manufacture of lakes, the tungstic acid is added to a solution of the dyestuff, and barium chloride or other suitable precipitant is added.—A. J. H.

Dyeing tops, yarn and the like; Apparatus for ——. A. Ashworth. U.S.P. 1,374,628, 12.4.21. Appl., 15.10.20.

A PERFORATED tube is mounted vertically within a dyeing vat, and means are provided for forcing a dye or mordant liquor through the tube and a series of collectively collapsible tubular yarn spools which are mounted upon it.—A. J. H.

Warp-dyeing machine. W. F. Haskell. U.S.P. 1,375,389, 19.4.21. Appl., 4.4.18. Renewed 15.9.20.

WARP yarn is drawn through a series of unit coils each having inlets for the dye liquor, which is supplied to the last unit. The overflow for exhausted liquor from the last unit is connected with the inlet of one of the preceding units.—A. J. H.

Silks; Process of treating [dyeing grege] ——. E. L. Maupai. E.P. 161,625, 10.12.19.

Dyeing paper pulp. Huebner. *See* V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Concentration of ——. E. Galle. Z. angew. Chem., 1921, 34, 168—170, 173—175.

NITRIC acid prepared by the oxidation of atmospheric nitrogen or of ammonia always has to be concentrated, the highest initial strength obtained

being 50% HNO_3. The Pauling tower as improved by Hoenig is used for this purpose. The tower, about 8 m. high, is made of cast iron rings lined with acid-resistant material, and packed with Raschig rings carried on silicon-iron grids interposed between adjacent sections. The uppermost section, which is not packed, includes a stoneware acid distributor, a gas-exit pipe to the nitric acid cooler, acid-feed pipes, and thermometer. The bottom section is fitted with a manhole, steam-jet, and run-off pipe for dilute denitrated sulphuric acid. The nitric acid cooler is a worm of silicon-iron, and any uncondensed gases are drawn by a stoneware injector to an absorbing tower, the weak acid from which is returned to the process. The acids are elevated by silicon-iron pumps with chromium-steel shafts. The process is started by feeding with concentrated sulphuric acid and blowing in steam until the temperature at the top reaches 130° C. In normal working the temperature at the top of the tower stands at about 112° C. The quantity of sulphuric acid required depends on the dilution of the nitric acid. With the usual nitric acid of 1·26 sp. gr., 5 pts. of sulphuric acid to 1 pt. of nitric acid is required. The sulphuric acid may be replaced by an equivalent quantity of the same in the form of mixed waste-acid. In the case of nitric acid containing hydrochloric acid the consumption of sulphuric acid is greater. Laboratory experiments showed that, with an effective fractionating column, dilute nitric acid can be concentrated up to 65% HNO_3 without the use of sulphuric acid with no appreciable loss. To complete the concentration of this acid 2 pts. of sulphuric acid (monohydrate) is required for each 1 pt. of water present in the nitric acid. The large-scale application of this method would effect a great increase in the capacity of a given plant and saving in sulphuric acid. The addition of hydrochloric acid to the mixed acids greatly raises the boiling point, necessitating more sulphuric acid, and in addition the latter must be in excess to prevent formation of nitrosyl chloride. In the case of mixed waste acids about 50% of the N_2O_4 present is oxidised during distillation, but absorption in alkali is advisable to recover the remainder.—C. I.

Electrolytic cells; Marsh —— for chlorine, caustic soda, and hydrogen. C. W. Marsh. Trans. Amer. Electrochem. Soc., 1921, 297—306. [Advance copy.]

The Marsh electrolytic cell comprises a top of stoneware or other suitable material shaped like an inverted trough with ends extended downwards. The cell is suspended from this, or supported in a box, and from the top are also suspended the anodes, whilst the cathode is clamped to the top and ends. Openings are provided in the top for brine inlet, brine control device, brine level indicator, brine gauge glass, chlorine outlet, and for cleaning purposes. The anodes consist of graphite rods, 4·4 cm. diam. and 60 cm. long, arranged one above the other with spaces between, and are fixed to a rectangular graphite section. The cathode of perforated sheet steel is corrugated to conform to the surface of the horizontal graphite rods, and an asbestos paper diaphragm is tightly clamped to the edges of the cathode. The cathode with the ends and top forms the electrolytic compartment; it may be confined if the hydrogen gas is to be recovered. For small industrial plants and water and sewage purification, batteries of 100—300 amps. are suitable; the cells measure 25×72×80 cm. and a battery of 15 cells yields 5·5 kg. of chlorine, 6·1 kg. of caustic soda, and 0·15 kg. of hydrogen per hour. Normally, the life of the batteries is six months and of the anodes two years. The cost of chlorine from such a plant, taking into account the value of the caustic soda, is 4·5—5·0 cents per lb., as compared with liquid chlorine at 12 cents per lb. For large electrolytic alkali, bleach, and chlorine plants, batteries of 1250 to 5000 amps. are used. The cells measure 25×134 cm. and have a voltage of 3·35 and power efficiency of 63%. The batteries can be operated at double capacity, the current available then being 2500—10,000 amps. In this case the cells measure 25 cm.×5 m.; the voltage will be 4, and the power efficiency 50%. Over long periods the ampère efficiency amounts to approximately 90%; it may reach 95—97%. Features of the Marsh cell are the low average voltage resulting from the provision of a large electrode surface, regular distribution of deposits on the diaphragms preventing clogging of the passages, good circulation, and effective removal of chlorine bubbles. Small cells of large capacities operating at high efficiencies can thus be successfully employed.—W. J. W.

Ammonia synthesis equilibrium; Interpretations of ——. R. S. Tour. J. Ind. Eng. Chem., 1921, 13, 298—300.

Equilibrium in the reaction $\frac{1}{2}N_2+\frac{3}{2}H_2 \rightleftarrows NH_3$ may be expressed by the formula $a/(1-a-c)^2 = KP(r^{3/2})/(1+r)^2$ where a=volume fraction of ammonia at equilibrium, c=volume fraction of inert gases at equilibrium, r=volume ratio of hydrogen to nitrogen at equilibrium, P=total pressure in atm., and K is a function of the absolute temperature. A set of curves shows the effect on the ammonia content at equilibrium of a variation of any one of the conditions when the others have the arbitrary values: T=773° abs., P=100 atm., r=3, c=0. Both curves and equation show that effect of temperature is very marked; a reduction from 500° to 485° C. is as advantageous as a rise in pressure from 100 to 120 atm. Pressure increases the ammonia content at a decreasing rate with increasing ammonia content. Changes in the ratio of hydrogen to nitrogen have a small effect; a variation from the theoretical to the ratio $2N_2:3H_2$ or to $0·5N_2:3H_2$ involves a reduction of less than 10% of the equilibrium content. The effect of inert diluents is not only to lower the partial pressures of the reacting gases, but to dilute these as well. Each of the terms of the equation may be plotted as a separate curve for the sake of simplicity in computation, and a simple nomograph has been constructed for determining the equilibrium ammonia content when only temperature and pressure are variable, r has its theoretical value of 3·0, and c=0.—W. J. W.

Hydrogen for the synthesis of ammonia; Manufacture of ——. G. Claude. Comptes rend., 1921, 172, 974—977.

The source of hydrogen suggested is water-gas, town gas, or coke-oven gas. In order to separate the hydrogen and the carbon monoxide the author suggests the use of solvents under pressure. By the use of ether under a pressure of 100 atm. and a temperature of about −50° C. it is easily possible to obtain hydrogen containing less than 0·2% of carbon monoxide. This pressure should not be greatly exceeded, as above this limit the solubility of hydrogen in the solvent increases very rapidly in proportion to that of the carbon monoxide.—W. G.

Potassium compounds; Application of the vapour pressures of —— to the study of the recovery of potash [from silicates] by volatilisation. D. D. Jackson and J. J. Morgan. J. Ind. Eng. Chem., 1921, 13, 292—295.

The information gained from experiments on the vapour pressures of potassium compounds (J., 1921, 177 A) has been applied to an investigation of their volatilisation. If greensand is heated with lime to 1300° C., up to 90% of the potash is volatilised, whereas in the case of felspar not more than 20% is obtained, the explanation lying in the fact that the

water liberated from the former silicate assists the formation of potassium hydroxide which has a high vapour pressure. The efficiency of calcium chloride, in admixture with lime, as a volatilising agent, was tested with glauconite and felspar, in such proportions as to give a residue having the composition of Portland cement. In the case of glauconite, volatilisation was practically complete, even at 1215° C.; with felspar it was less so. Contrary to Spackman and Cornwell's claims (U.S.P. 1,202,327; J., 1916, 1221), it was found that when sufficient chloride is present in the mixture to form potassium chloride, no advantage is gained by introducing water vapour. From mixtures of greensand with limestone in smaller proportions than required for Portland cement, without addition of a chloride, volatilisation is very small up to 1170° C., even in presence of water vapour; but if a chloride is added, mixtures containing only one-third of limestone, heated just below their fusing point, show a high volatilisation of the potassium compound. As a volatilising agent sodium chloride appears to be superior to calcium chloride.—W. J. W.

Potassium salts; Solubility of different —— in mixtures of water and alcohol. M. Pierrat. Comptes rend., 1921, **172**, 1041—1043.

THE solubility at 14° C. in aqueous alcohol of varying concentrations and the electrical conductivity of aqueous solutions containing the same weight of salt in a volume of water equal to that of the aqueous alcohol have been determined for the bitartrate, perchlorate, platinichloride, fluosilicate, and cobaltinitrite of potassium. The solubilities, in g. per l., in alcohol of 94·7% concentration (by weight) at 14° C., of the different salts in the order given above are 0·05, 0·15, 0·02, 0·0096, 0·026.

—W. G.

Sodium sulphide; Action of —— on ferric oxide. J. C. Witt. J. Amer. Chem. Soc., 1921, **43**, 734—740.

AN excess of sodium sulphide converts ferric oxide into a black amorphous substance, which after removal of most of the sodium sulphide dissolves in water to form a brilliant green solution. The solution is a reversible sol containing less than 0·07 g. of iron per litre. (*Cf.* J.C.S., June).—J. F. S.

Sodium silicate; Manufacture of ——. A. A. Perazzo. Anal. Soc. Quim. Argentina, 1920, **8**, 404—409.

AN improved plant for the preparation of sodium silicate by fusion is described. The furnace is rectangular in plan and is divided into two unequal portions by a bridge which is so constructed that only fused material can pass under it while floating unmelted material is held back. When a fresh charge is delivered into the larger compartment the fused sodium silicate is forced under the bridge into the smaller compartment of the furnace and overflows into a tank which is maintained full of cold water. The sudden cooling of the fused silicate produces a fine granular product. The apparatus is continuous in working and the product obtained is more readily dissolved than that obtained by older methods involving the use of grinding machinery.

—G. W. R.

Fluorides; Modification of Starck and Thorin's method for the determination of ——. E. D. Garcia. Anal. Soc. Quim. Argentina, 1920, **8**, 321—324.

STARCK and Thorin's method (J., 1912, 259) for the estimation of fluorides in aqueous solution is modified, the excess of calcium in the filtrate from the mixed precipitate of calcium oxalate and fluoride being estimated volumetrically. Knowing the amount of calcium required for the calcium oxalate, the amount of calcium fluoride and, hence, the percentage of fluorine in the original solution is obtained. Insoluble fluorides are first fused with silica and sodium carbonate. After treatment of the mass with water, silica is removed by ammonium carbonate and fluorine estimated as above.

—G. W. R.

Hypochlorous acid; Electrometric titration of ——. W. D. Treadwell. Helv. Chim. Acta, 1921, **4**, 396—405.

WHEN hypochlorite is titrated with either arsenious acid or potassium iodide the end point may be determined accurately by electrometric means. The comparison electrode employed consists of a glass tube about 8 cm. in length, with its end drawn out to a capillary and turned up and the extremity of the capillary closed by a plug of filter paper or a drop of gelatin containing potassium sulphate. In this tube is placed potassium sulphate solution mixed with either a little hypochlorite solution already titrated or a drop of about $N/100$ iodine solution containing iodide. As electrodes use is made of two smooth platinum wires, one dipping into the hypochlorite solution and the other fairly deeply into the comparison electrode. These two electrodes communicate by way of either a high-resistance millivoltmeter or a galvanometer with suitable resistance. A sudden drop of the galvanometer deflection to zero marks the end point. When arsenious acid solution is used, the alkaline hypochlorite should be neutralised and at once titrated, but the loss due to premature formation of chlorate is inappreciable if the titration is carried out in dilute solution, at the room temperature, and within a few minutes of neutralisation. The end point becomes indistinct if a solution containing alkali carbonate or hydroxide is titrated with arsenious acid. The optimal hydrogen-ion concentration for the end point of the titration of a hypochlorite with potassium iodide, calculated from the equilibrium, $IO_3'+5I'+6H^{\cdot} \rightleftarrows 3H_2O+3I_2$, is 10^{-7}, which is that of the neutral point. The fundamental objection to this method is the pronounced sensitiveness of the end point to the reaction, and Pontius (J., 1904, 133), who devised the method, made use of a highly alkaline solution $[(H^{\cdot})=10^{-9}]$, which retards the end point. Good results are obtained with a solution alkaline with bicarbonate if the available chlorine amounts to about 0·1 equivalent per litre, but $N/100$ hypochlorite solution yields unreliable values under these conditions. When a very dilute solution is titrated, the final stages must be carried out very slowly, otherwise the blue coloration of the starch appears too late.

—T. H. P.

Hydrocyanic acid; Formation of —— in plants. P. Menaul. J. Biol. Chem., 1921, **46**, 297.

THE formation of hydrocyanic acid was observed *in vitro* in sunlight, in a solution containing potassium nitrate and formaldehyde, but only if the reaction was acid to methyl orange. It is suggested that hydrocyanic acid may thus be formed in plants.—G. B.

Hydrofluosilicic acid; Equilibria of ——. L. J. Hudleston and H. Bassett. Chem. Soc. Trans., 1921, **119**, 403—416.

THE standard "Analytical Reagent" methods for the detection of silica in hydrofluoric acid are inadequate. The proportion of hydrofluosilicic acid in mixtures with hydrofluoric acid can be determined by complete neutralisation with sodium hydroxide (*cf.* Wagner and Ross, J. Ind. Eng. Chem., 1917, **9**, 1116), according to the equation, $H_2SiF_6+6NaOH=6NaF+H_2SiO_3+3H_2O$. The estimation is carried out in conical flasks of wax or waxed glass, closed with rubber stoppers and con-

taining measured quantities of sodium hydroxide coloured with phenolphthalein. Weighed quantities of the mixed acids are placed in wax test tubes inside the flasks and the contents of both mixed by shaking. When the colour has faded (the time being measured), further alkali is run in until permanent neutralisation is reached. If n c.c. of alkali were originally present and N c.c. were required for total neutralisation, $(N-n)/N\times100$ is the percentage of total non-available hydrion (*i.e.*, the "complex" hydrofluosilicic acid) in the solution at the moment of fading. From the different values for this figure a value for the initial concentration of the complex, *i.e.*, the percentage of hydrofluosilicic acid initially present in the mixture, can be calculated. For concentrated solutions the measurement of $(N-n)/N \times 100$ is accurate to 0·25%, but for dilute solutions only to 1%. The time readings, due to the difficulty of bringing about complete mixing, and measurement of temperature due to heat of reaction, are also liable to error. The rate of dissociation of sodium silicofluoride into silicon tetrafluoride and sodium fluoride has been determined, together with the formula for the variation of the velocity constant with temperature. The equilibria set up when silicon tetrafluoride is passed into water are discussed. All four substances—hydrofluosilicic acid, hydrofluoric acid, silicic acid, and unchanged silicon tetrafluoride — are present, though in small concentration. Silicic acid is shown to exist in true solution to the extent of at least 0·003 mol. per litre at 15° C.—P. V. M.

Hydrogen peroxide; Kinetics of the decomposition of ——. F. Bürki and F. Schaaf. Helv. Chim. Acta, 1921, 4, 418—425.

Decomposition of hydrogen peroxide in alkaline solution is a reaction of the first order, the velocity of the reaction being dependent on the concentration of the base but independent of its nature and conditioned apparently by the concentration of the hydroxyl ion alone.—T. H. P.

Carbon; Adsorption by ——. H. Herbst. Biochem. Zeits., 1921, 115, 207—219.

The adsorptive power of charcoal depends partly on the content of pure amorphous carbon, and can in some cases be increased by removing tarry impurities by means of a solvent or by distillation, or by destroying them by chemical means, as in the Aussig zinc chloride process. At about 1150° C. charcoal is fairly rapidly transformed into graphite and becomes a less powerful adsorbent. The author has prepared pure amorphous carbon of maximal adsorptive power, and expresses the "true" activity of technical samples as percentages of the former (comparison by CO_2 isotherm). Experiments with gaseous chloropicrin, benzyl chloride, and phosphorus tribromide, lead to the conclusion that in each case 1 mol. is fixed by 6 atoms of pure carbon, probably present as a C_6-ring.—G. B.

Nitric acid. Longinescu and Chaborski. *See* XXIII.

Patents.

Sulphuric acid, Concentration of —— *in a vacuum.* Badische Anilin- u. Soda-Fabr. G.P. 302,553, 12.1.17.

A heating chamber is provided with pipes of perforated sheet iron coated internally with lead which is connected homogeneously to the iron at the perforations. The exterior of the pipes may also be covered with lead. These pipes resist the chemical action of the boiling liquid and also the difference of pressure. The chamber is also lined with lead, and a continuous process is practicable.—C. I.

Ammonia oxidation; Process for the activation of contact masses for catalytic ——. Badische Anilin- u. Soda-Fabr. G.P. 304,232, 27.1.15.

The activating material is applied to the catalyst in a state of fine division in the reaction chamber. This method may be applied to the revival of old contact masses without interference with the process. In the case of a contact mass containing bismuth, an acid solution of bismuth nitrate containing 10% Bi is injected into the reaction chamber.—C. I.

Sulphate kilns; Apparatus for the introduction of sulphuric acid into mechanical ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 332,954, 29.11.19. Addn. to 331,238 (J., 1921, 301A).

In place of an acid feed vessel, a pipe secured to the rotating spindle and curved at the end is used. —C. I.

Sulphur dioxide; Obtaining and utilising —— *from blast-furnace slag.* L. H. Diehl. E.P. 139,172, 16.2.20. Conv., 16.1.17.

For the recovery of sulphur, existing as sulphide from blast-furnace slag, a current of air, preferably heated, is blown through, or led over the slag in sufficient amount to give a gas mixture containing not less than 2% SO_2, whilst at the same time avoiding solidification of the slag or further oxidation of its contained metallic oxides. The operation may be conducted in a slag pan with hood and gas outlet, or in a covered sump inserted in the slag run. In conjunction with the air oxidation, the introduction of oxidising compounds, such as calcium sulphate, is recommended, these being added in a highly heated or molten condition. The sulphur dioxide recovered is free from arsenic (Reference is directed, in pursuance of Sect. 7 Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 11,544 of 1899 and 2405 of 1908 J., 1899, 444; 1908, 1209.)—W. J. W.

Percarbonates; Manufacture of ——. Deutsche Gold- u. Silber-Scheide Anstalt vorm. Rössler. E.P. 117,085, 24.6.18. Conv., 25.6.17.

Alkali percarbonates mixed with carbonates are prepared by interaction of alkali peroxide and bicarbonate in presence of a limited amount of water. The percarbonate is separated from crystallised carbonate and salted out by addition of sodium chloride. Negative catalysts such as alkali silicates, stannic acid, or gums may be added to the percarbonate solution.—C. I.

Iron salt [for tanning]; Production of a solid non-hygroscopic ——. O. Röhm. E.P. 146,214, 26.6.20. Conv., 27.12.18.

By the action of chlorine on ferrous sulphate, whether in the solid state or in solution, a non-hygroscopic compound of the composition $FeSO_4Cl$ is obtainable, which is specially suitable for tanning purposes.—D. F. T.

Ammonia; Method of and means for use in manufacture of [aqueous] ——. R. P. Douglas. E.P. 161,244, 31.12.19.

A portion of the vapours from the liming chamber of an ammonia still is passed through a reflux condenser to remove water, and thence to a finishing condenser, where strong aqueous ammonia is obtained.—C. I.

Ammonia; Process for the preparation of —— *from nitrogen.* H. Hampel and R. Steinau. G.P. 310,761, 24.8.17.

A metal is treated at high temperature and pressure with hydrogen and with ammonium chloride

or other ammonium compound or other substance which liberates nascent hydrogen. The ammonium or metallic salt used is recovered, as also is the metal, by reduction of the oxide or carbonate formed either directly or as a result of subsequent reactions.—C. I.

Ammonia and ammonium sulphate; Production of —— by the action of steam on cyanogen compounds formed in the distillation of organic nitrogen compounds. F. J. Collin, A.-G. zur Verwertung von Brennstoffen und Metallen. G.P. 328,829, 18.5.19.

A MIXTURE of gas containing cyanogen and steam, after removal of free ammonia, is treated with excess of sulphuric acid, with continual heating, *e.g.*, in a column apparatus, whereby the cyanogen is converted into ammonia, which combines with the acid to form ammonium sulphate. In the case of gases of low cyanogen content the cyanogen is absorbed in water or ammoniacal liquor, the resulting liquor is distilled, the ammonia absorbed, and the waste gases from the sulphate saturator treated as described. The reaction velocity is increased by the presence of hydrogen sulphide.—C. I.

Ammonium bicarbonate; Preparation of dry —— from wet precipitated salt. Badische Anilin- u. Soda-Fabr. G.P. 301,674, 12.1.16.

THE salt is thoroughly exposed to a counter current of warm, indifferent gases (air, carbon dioxide, or flue-gases) which have passed through a drying chamber.—C. I.

Sodium pyrophosphate; Manufacture of acid ——. A. Kelly. E.P. 161,273, 5.1.20.

THE calculated amount of acid, *e.g.*, hydrochloric acid, is added to a strong solution of sodium pyrophosphate, and the acid salt precipitated by saturating with sodium chloride.—C. I.

Phosphatic materials; Process of sintering ——. F. S. Washburn, Assr. to American Cyanamid Co. U.S.P. 1,373,471, 5.4.21. Appl., 23.7.20.

A MIXTURE of phosphatic and silicious materials is sintered to form a porous mass which is mixed with carbon and heated in an electric furnace, the evolved phosphorus being recovered.—W. J. W.

Aluminous compounds; Manufacture of ——. P. Spence and Sons, Ltd., H. Spence, and W. B. Llewellyn. E.P. 161,606, 11.10.19.

THE process in which iron is precipitated from aluminium sulphate solution by addition of a potassium salt and 5—10% excess of alumina (E.P. 9148 of 1914; J., 1915, 799) is made more rapid by adding to the solution a proportion of impalpable mud. This is prepared by grinding the silicious residues from the treatment of aluminous minerals, or native alunite may be used. The basic ferric potassium sulphate is then readily separated from the liquor. Part of it is used for a fresh operation, and the valuable constituents in the mud are thus gradually concentrated and may be recovered. —C. I.

Aluminium hydroxide; Manufacture of ——. M. Lindner. G.P. 333,388, 1.5.18.

STRONGLY cooled dilute solutions of aluminium salts are added to dilute and strongly cooled solutions of ammonia, which are kept vigorously stirred by means of a current of air saturated with ammonia. Aluminium hydroxide is thereby precipitated in a light gelatinous form (sp. gr. about 1) possessing a high adsorptive power.—A. R. P.

[Aluminium sulphate;] Treatment of colloid-containing mediums [e.g., in ore flotation, and in manufacture of ——]. W. A. Deane, Assr. to The Dorr Co. U.S.P. 1,359,037, 16.11.20. Appl., 13.1.20.

THE product obtained by the action of sulphuric acid on bauxite is treated with "packing-house stick" (an organic gel obtained as a by-product in the packing-house industry by boiling waste meat products etc. with water), whereby colloidal impurities (clay, silica, etc.) are coagulated and can be easily separated. Packing-house stick may also be used as a dispersing medium in ore flotation processes; the deflocculated colloids are separated from the ore pulp by decantation, and their interference in the subsequent flotation operation thus avoided.

Copper sulphate; Process of obtaining —— from metallic copper. P. A. Mackay. E.P. 161,656, 9.1.20.

REFINED or blister copper is dissolved in hot 70% sulphuric acid in presence of silver nitrate or other salt of a metal more electronegative than copper. Blister copper often contains enough silver for the purpose, and in this case only nitric acid is added. Excess of metal is used, and the silver etc. is deposited on the residual copper.—C. I.

Potassium carbonate; Method of making ——. E. P. Stevenson, Assr. to A. D. Little, Inc. U.S.P. 1,360,046, 23.11.20. Appl., 19.1.20.

A SOLUTION of potassium acetate in ethyl alcohol is treated with carbon dioxide, the potassium bicarbonate is separated, and the alcoholic solution is then treated with a reagent, *e.g.*, lime, to produce a salt (calcium acetate) of low solubility, which is used in making further quantities of potassium acetate.—W. J. W.

Potassium salts; Process for recovering —— from solutions carrying borates or carbonates or both. C. E. Dolbear, Assr. to D. C. Norcross, J. H. Miller, and G. J. Henry. U.S.P. 1,373,179, 29.3.21. Appl., 30.10.19.

SOLUTIONS of potassium salts containing boron compounds are treated with an aluminium compound, the insoluble aluminium borate is removed, and the potassium salt recovered from the residual solution. —W. J. W.

Alkali sulphides; Process of making ——. W. H. Landers, Assr. to H. S. Loud. U.S.P. 1,374,209, 12.4.21. Appl., 17.11.19.

AN alkali salt of a volatile mineral acid is intimately mixed with "sludge-acid" containing at least 5% of carbon, and the mixture heated to reduce the sulphate formed to sulphide.—C. I.

Carbides and derivatives thereof; Process and apparatus for manufacture of ——. F. E. Norton. U.S.P. 1,374,317, 12.4.21. Appl., 1.4.18.

IN a continuous process for the manufacture of carbides from a mixture of carbon and oxides or hydroxides, the necessary heat is supplied by combustion of part of the carbon with oxygen.—C. I.

Basic melts rich in lime; Process for the preparation of ——. L. H. Diehl. G.P. 307,190, 21.12.17.

A MIXTURE of about molecular equivalents of calcium oxide and sulphate is melted with an easily fusible compound, such as sodium chloride, calcium chloride, sodium hydroxide, or sodium sulphate. Limestone may be used in place of lime. The melt can be used for the decomposition of sulphides in furnace slags by agitating them with a current of air and adding the basic mixture, preferably in a molten state. Sulphur dioxide is evolved by the

interaction of sulphide, sulphate, and air; the residual slag is granulated and the granular mass dried and powdered to the fineness of cement.—C. I.

Hydrogen peroxide; Process of obtaining solid compounds of ——. E. Merck. G.P. 331,111, 29.3.12. Addn. to 303,680 (J., 1918, 371 A).

Hydrogen peroxide solutions rendered stable by the methods described in G.P. 174,190, 203,019, and 216,263 (J., 1908, 1204; 1909, 1314) are evaporated with neutral organic or inorganic carriers. Hydrogen peroxide is thus obtained in combination with the substance used in a solid stable state. —C. I.

Hydrogen; Manufacture of —— by dissolving iron in sulphuric acid. R. Blum and M. Buchner. G.P. 303,281, 8.1.16.

Iron is treated with the equivalent quantity of sulphuric acid, with the application of heat or pressure, or both, for the production of hydrogen. The resulting ferrous sulphate is calcined in a current of air to ferric oxide with the evolution of sulphur trioxide, which is re-converted into sulphuric acid and used again in the process together with the iron resulting from the reduction of the ferric oxide.—A. R. P.

Silica gels and processes of making same. W. A. Patrick. E.P. 136,543, 6.12.19. Conv., 7.12.18.

See U.S.P. 1,297,724 of 1919; J., 1919, 363 A.

Alumina and its salts; Process for the extraction of —— from clay. H. G. Wildman. E.P. 161,310, 14.1.20.

See U.S.P. 1,326,384 of 1919; J., 1920, 191 A.

Cyanogen compounds; Process for recovering ——. E. V. Espenhahn. Reissue 15,090, 19.4.21, of U.S.P. 1,315,219, 9.9.19. Appl., 17.1.21.

See E.P. 109,254 of 1917; J., 1918, 570 A.

Zinc sulphide; Manufacture of ——. P. Comment. U.S.P. 1,374,435, 12.4.21. Appl., 23.4.19.

Mixed acid. G.P. 303,892. *See* XXII.

VIII.—GLASS; CERAMICS.

Clays; Effect of time on the drying shrinkage of ——. R. F. Geller. J. Amer. Ceram. Soc., 1921, 4, 282—287.

The drying shrinkages of three shales, two ball-clays, and one fireclay were determined to ascertain how quickly different clays could be dried and to examine the influence of the time of drying on the total shrinkage. The volume shrinkages were determined in each case. It was concluded that the time required for drying depended largely on the water content, but that the structure of the clay was an important factor, fine-grained clays such as ball-clays not being dried at so rapid a rate as clays of coarser grain. The total shrinkage was proportional to the water content and was not influenced by the rapidity of drying.—H. S. H.

Kaolin; Formation and constitution of ——. V. J. Bernaola. Anal. Soc. Quím. Argentina, 1920, 8, 392—400.

A theoretical discussion of the origin of kaolin from felspars and the supposed occurrence in it of crystalline particles. (*Cf.* J.C.S., June.)—G. W. R.

Silica bricks from quartzite rock; Possibility of preparing high-grade ——. E. Lux. Stahl u. Eisen, 1921, 41, 258—264.

Silica bricks can be made from quartzite rock of a quality corresponding with those made from tertiary quartz. These bricks show under the microscope a high degree of transformation even of the large quartzite grains. Such a transformation is effected in the case of quartzite rock by a high burning temperature such as is employed in America. The degree of transformation of German silica bricks is usually of a much lower order, but microscopical examination of the better bricks shows that by arranging the method of manufacture to suit the raw material, a brick may be made which is not inferior to those prepared from tertiary quartz.—J. W. D.

Enamel pigment; Manufacture of a red —— from cadmium sulphide and selenium. S. Sugie. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, 24, 252—258.

Red enamel pigments known as "fire-red" or "cadmium-red" are prepared from a mixture of 80—90% of cadmium sulphide and 20—10% of selenium, the dried and finely powdered components being well mixed and heated in a clay crucible in a muffle furnace at about 700° C. When the blue flame, which burns at the mouth of the crucible, is nearly extinguished, the crucible is removed from the furnace and the product is immediately cooled either by spreading it over a cold place or by pouring cold water over it. The product probably has the empirical formula Cd_3SeS_2.—K. K.

Enamelling oven; An electric vitreous ——. C. W. Mehling and J. W. Carpenter. J. Amer. Ceram. Soc., 1921, 4, 271—276.

An electric oven eliminates the risk of damaged ware which is always present with oil-, coal-, and gas-fired furnaces and permits the use of the entire heating space. Its initial cost is higher, as is also the power cost per hour compared with that of fuel, but the cost per pound of metal dealt with is actually in favour of the electric oven. Details of the construction are given. The oven, which is wound with nichrome ribbon, can be operated up to 1800° F. (980° C.). The finish of the ware is more satisfactory than with the older types of furnace.—H. S. H.

Patents.

Electric insulating material; Manufacture of ——. E. F. A. Bültemann. E.P. 137,326, 2.1.20. Conv., 29.1.18.

A fireproof, heat-resisting insulating material, insensitive to moisture, is prepared by mixing substances capable of setting hydraulically, such as cements, plaster, magnesium, oxychloride, etc., with easily fusible insulating substances, such as resins, bitumens, asphalts, sulphur, etc., and vegetable or mineral fibrous filling material, such as cellulose, asbestos, peat, slag wool, glass wool, etc. The mixture is treated with water, preferably under pressure, allowed to harden, dried, and heated, whereby the fusible substances soften and fill up the pores of the mass.—J. S. G. T.

Refractory insulation. P. G. Willetts. U.S.P. 1,374,538, 12.4.21. Appl., 17.12.19.

A refractory heat-insulating material is prepared by burning a mixture of finely divided lignite and plastic fireclay having a high silica content. —J. S. G. T.

Ceramic pastes; Process and apparatus for dewatering ——. O. Frank. G.P. 330,224, 31.10.18.

In order to reduce the water content of ceramic pastes so as to leave a mass suitable for shaping, the paste is placed in an apparatus consisting of clay plates with narrow feet so arranged that there is a hollow cavity between them. By reducing the

air pressure in this chamber the excess water is sucked through the top plate and is removed by passing a current of air through the chamber. —A. R. P.

Kiln, especially for enamelled ware. A. Sommer. G.P. 325,747, 15.12.18.

THE kiln is heated indirectly by hot gases conveyed through channels of refractory brick running along the side walls and roof, but at a distance from the same.—L. A. C.

Refractory and insulating products; Manufacture of ——. G. L. Dimitri and J. E. Delaunay. U.S.P. 1,374,493, 12.4.21. Appl., 21.6.20.

SEE E.P. 142,513 of 1920; J., 1921, 348 A.

IX.—BUILDING MATERIALS.

Gypsum; Relation between the fineness and other properties of calcined ——. W. E. Emley and F. C. Welch. J. Amer. Ceram. Soc., 1921, 4, 301—305.

CALCINED gypsum was screened to provide material of different sizes. Each size was tested for normal consistency (measured by the Southard viscosimeter), time of set (measured by a Vicat needle), tensile strength, combined water, and plasticity (measured by spreading a paste of normal consistency upon a porcelain plate of known absorptive capacity at a constant rate). The results indicated that the finer the calcined gypsum the more water was required to make a paste of normal consistency and the more quickly did it set. Within the limits of the specifications of the American Society for Testing Materials, increased fineness of the calcined gypsum was accompanied by increased strength of the set material, but any increase of fineness beyond this resulted in decreased strength. The finer the calcined gypsum the more sand would it carry. —H. S. H.

Blast-furnace slags; Experiments on ——. H. Burchartz. Stahl u. Eisen, 1921, 41, 193—200. (*Cf.* J., 1920, 573 A.)

EXPERIMENTS on the suitability of blast-furnace slag for incorporation in concrete mixings have been extended to include ferroconcrete exposed to the action of sea water. Here the durability of the concrete depends largely on its density, and in this respect the concretes tried proved satisfactory and at least equal to those made with sand. The standard mixture consisted of 1 pt. (by vol.) of cement, 2 pts. of slag dust, and 3 pts. of slag particles of grade ranging from 7 mm. to 40 mm. Compression tests were made on specimens after various periods of hardening up to 3 years. Slag concretes were stronger at all periods than sand concretes. They were also sufficiently impervious to prevent percolation of sea water and rusting of the iron cores.—H. J. H.

Blast-furnace slags; Strength of ——. H. Burchartz. Stahl u. Eisen, 1921, 41, 472—475.

THE view that the suitability of slag as building and road-making material can be correlated with its colour and composition has been examined by experiments on ten samples of blast-furnace slag. The samples were tested in compression, while resistance to wear was measured by noting loss in weight when the specimens were placed in a rotating drum for half an hour. The mean compressive strengths of the samples ranged from 768 to 2414 kg. per sq. cm. High mechanical strength appeared to be associated with dark colour and high content of iron and manganese. Resistance to wear was associated with compressive strength, but the connexion was not quantitatively rigid. The range of samples was, however, too restricted (seven being from one works) to allow of a wide generalisation.—H. J. H.

PATENTS.

Cement; Process of curing ——. G. L. Smith. U.S.P. 1,374,403, 12.4.21. Appl., 24.7.18.

ARTICLES of cement, cement mortar, or cement concrete are heated in air or a gas under a pressure greater than that of saturated steam at the temperature of the moisture within the pores of the material.—L. A. C.

Fibrous material [e.g., wood]; Method of treating ——. W. Weimar. U.S.P. 1,375,125, 19.4.21. Appl., 5.2.20.

THE material is rendered non-absorbent, and its insulating properties and texture are improved by successive immersion in a hot solution of sodium carbonate, a hot hydrocarbon liquid, and a solution of sulphur and resin at a temperature sufficiently high to keep the sulphur molten; the material is dried after the first two immersions, and after it has remained in the third solution for a sufficient period to fill the pores it is suddenly cooled. —L. A. C.

Heat insulators; Manufacture of moulded ——. P. Krause. G.P. 329,409, 29.3.19. Addn. to 317,170.

MOULDED articles prepared as described in the chief patent from the waste sludge of iron oxide and silicates obtained in the manufacture of alumina are heated, with or without the addition of a flux or an alkali, until they are partially vitrified. The porosity of the articles may be increased by adding combustible material, such as sawdust or cork waste, to the mixture before heating.—L. A. C.

Impervious acid-resisting apparatus; Manufacture of —— from cement. Freskoschmelz- und Mosaikwerke G.m.b.H. G.P. 332,940, 29.7.17.

A MIXTURE of cement with quartz or similar material and a flux is burnt, and the resulting mass, after grinding, is mixed with a further quantity of the flux and a binder, *e.g.*, Portland, Sorel, or zinc cements, water-glass, or a mixture of water-glass and an alkaline-earth oxide. The mixture is made into the required shape, which is then glazed and fired.—A. R. P.

Cement; Manufacture of ——. K. G. Wennerström. E.P. 143,243, 12.5.20. Conv., 10.2.19.

SEE U.S.P. 1,343,948 of 1920; J., 1920, 573 A.

Impregnated wood. G.P. 334,307. *See* IIB.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

[Steel] process; Deoxidation processes in the basic Bessemer ——. O. von Keil. Stahl u. Eisen, 1921, 41, 605—611.

A CAREFUL examination was made of two charges at each of nine steelworks. The oxygen was estimated by reduction at 950° C. An increase of oxygen was noticeable during the after-blow in two cases only; in other cases there was a diminution. The average limiting values of oxygen before deoxidation were 0·075 and 0·095%, and after deoxidation 0·030 and 0·040%. Percentages of oxygen determined by reduction at 950° and 1170° C. did not indicate any connexion between the progress of the smelting or the method of deoxidation and the percentage of oxygen. It was found that with less than 0·4% of manganese the oxygen value was high,

and with over 0·5% the oxygen value was lower. On account of the uncertainty of determining the oxygen completely by the method used, co-ordination between the oxygen percentages and the stages of the process cannot be affirmed. Further work on synthetic charges of known oxygen content is also necessary to establish the exact influence of manganese.—J. W. D.

Basic slag; Influence of basicity of —— on the working results of the converter. L. Blum. Stahl u. Eisen, 1921, **41**, 69—74.

The basicity of basic slag is limited by the proportion of free lime remaining in excess of that required for the formation of tetracalcium phosphate and calcium monosilicate. From consideration of a large number of works analyses it is concluded that for an economical basic process in regard to efficient dephosphorisation and low manganese consumption as well as to effective high desulphurisation and low loss of iron, the excess lime calculated as above should be about 4%.—J. W. D.

Iron and steel; Roentgen spectrographic investigations of ——. A. Westgren. Iron and Steel Inst., May, 1921. [Advance proof.] 23 pages.

The results of the investigations show that α-iron has a cube-centred cubic lattice structure, thus verifying Hull's result (Phys. Rev., 1917, **9**, 84; **10**, 661). At 800°—830° C., within the so-called β-iron interval, the iron atoms are oriented similar to those of α-iron. Adopting the view that allotropy is synonymous with polymorphy for solid crystalline substances, this means that β-iron cannot be considered as a separate modification of iron. In austenite and in iron at 1000° C. the crystals have face-centred cubic lattices. This is a characteristic of γ-iron and a fundamental crystallographic difference between α- and γ-iron. In martensite iron is present as its α-modification. This is also the case in high-speed steel of ordinary composition hardened at 1275° C.—J.W. D.

Iron; "Slip-lines" and twinning in electro-deposited ——. W. E. Hughes. Iron and Steel Inst., May, 1921. [Advance proof.] 9 pages.

Etched sections of electro-deposited iron, deposited under various conditions, exhibited peculiar lines or markings that appeared sometimes, and especially at low magnifications, as wave-lines running through the mass of the metal, and sometimes, on individual grains, in herring-bone arrangement. It is suggested that these lines are "slip-lines" which are produced in the grains of which the deposit is composed by the forces of contraction that act during the deposition.—J. W. D.

Iron; Solid solution of oxygen in ——. J. E. Stead. Iron and Steel Inst., May, 1921. [Advance proof.] 5 pages.

When iron is heated in air or oxidising gases, the surface layers apparently absorb oxygen which passes into solid solution, and when the solution becomes supersaturated the oxide separates forming globules of free oxide. These globules become larger and larger as oxidation proceeds, eventually joining together to form continuous layers. Oxidising gases find their most facile passage into the steel between the crystals. The gradual changes from solid solution to free oxide can be clearly traced along the oxidised junctions. Sulphur in the gases, possibly as sulphur dioxide, penetrates into the body of the crystals, producing manganese sulphide, and possibly protoxide, which appear in globular form. —J. W. D.

Iron; Cupric etching effects produced by phosphorus and oxygen in ——. J. H. Whiteley. Iron and Steel Inst., May, 1921. [Advance proof.] 13 pages.

Differences in the phosphorus content of less than 0·02% in adjacent parts of otherwise pure iron can be readily discovered by means of cupric etching reagents. As the difference increases up to 0·15% the contrast becomes more and more pronounced. These differences were produced by first phosphorising strips of iron with phosphorus in hydrogen at 1000° C. and then welding, in hydrogen or other gas, a pile made up of alternate strips of phosphorised and unphosphorised material. Attempts to produce in a similar way an unequal distribution of oxygen which could be detected by cupric reagents failed. When oxygen was present white resist-lines were formed only at the weld junctions, but these lines were not formed where unoxidised iron was welded in dry hydrogen. Two methods of obtaining an unequal oxygen content were used: first by soaking pure iron in its own oxide at a high temperature and then welding it with the unoxidised material; second by reducing highly oxidised iron in hydrogen and then welding it with the original metal at a low temperature.—J. W. D.

Iron; Baumann sulphur test and the behaviour of phosphorus in ——. P. Oberhoffer and A. Knipping. Stahl u. Eisen, 1921, **41**, 253—258.

Investigations were carried out on iron containing from 0·045 to 0·139% of sulphur, iron containing from 0·67 to 1·33% of phosphorus, and iron containing small percentages of both phosphorus and sulphur. As regards the Baumann sulphur printing test, results indicate its usefulness under all circumstances. A side reaction which occurs in the alloys containing phosphorus, due to the formation of hydrogen phosphide, is so small that it does not affect the bromide paper to any marked extent. With pure iron-phosphorus alloys annealing temperatures from 1200° C. upwards and a short heating at 1300° C. remove the dendritic phosphorus structure. This is the case only with pure iron-phosphorus alloys since the presence of carbon or other elements in solid solution in technical irons, such as steel, renders the homogenising so difficult that up to the present no practical heat treatment has been found sufficient to remove the dendritic segregation.—J. W. D.

Sulphur in steel; Comparison of different methods of estimating ——. T. E. Rooney. Iron and Steel Inst., May, 1921. [Advance proof.] 13 pages.

In the great majority of cases drillings of ordinary commercial carbon steels need not be annealed before estimating sulphur by the evolution method unless incipient rusting has taken place or the presence of elements such as titanium is suspected. Annealing may be necessary with steel low in manganese and containing chromium and liable to contain oxides which may form an eutectic with the sulphide. No definite conclusions could be drawn from experiments carried out on nickel-chromium steels, including annealing in hydrogen, as only two of the samples were of the type yielding low results by the evolution method, and further work is necessary to determine the cause of this condition in nickel-chromium steels.—T. H. Bu.

Pig iron containing manganese; Production of —— from low-manganese residues, especially Siegerland blast-furnace slag. H. Thaler. Stahl u. Eisen, 1921, **41**, 249—253, 338—343.

A series of experiments was carried out with Siegerland blast-furnace slag containing approximately 12·25% MnO. Different charges of this slag

mixed with varying proportions of iron ores were reduced with carbon using calcium phosphate and limestone as a flux. The reductions were carried out in a small electric furnace, and pig irons containing manganese and ferro-manganese alloys were produced. Economical results were obtained both as regards the percentages of manganese reduced and also as regards cost.—J. W. D.

Quenching cracks [in steel]; Cause of ——. K. Honda, T. Matsushita, and S. Idei. Iron and Steel Inst., May, 1921. [Advance proof.] 16 pages. (*Cf.* J., 1919, 582 A.)

OWING to the presence of arrested austenite in martensite the periphery of quenched small pieces of steel is harder than, as hard as, or softer than the interior according as the quenching is soft, medium, or hard respectively. When the interior is much harder than the periphery, quenching cracks occur, due to the smaller specific volume of the austenite as compared with the martensite of the central portion, which exerts a tangential stress on the periphery. This difference in specific volumes increases as the temperature falls, and cracking usually takes place at room temperature. In the case of a large specimen cracking may take place either at room temperature or in the A1 range. In the latter case the stress is caused by the structural difference between the inner pearlitic and the outer austenitic structures. In a hard quenching, owing to a gradual transformation of the arrested austenite the hardness generally increases with lapse of time. —T. H. Bu.

Tungsten tool steel; Prevention of hardening cracks and the effect of controlling recalescence in a——. S. N. Brayshaw. Iron and Steel Inst., May, 1921. [Advance proof.] 86 pages.

THE changes Ac 1.2.3 and Ar 3.2.1 in a tool steel containing 1·1% C and 0·8—0·9% W take place in stages which may be separated from each other if sufficient time be allowed for the process. By annealing bars at temperatures corresponding to the completion of the stages of the change point and afterwards subjecting them to a standard hardening process, they were found to lengthen or shorten and respond under bending stress according to the heat treatment received. Milling cutter blanks were heat-treated along with the bars and the blanks machined to a design extremely difficult to harden. The cutters were then subjected to the standard hardening process and it was found that the resulting cracks occur in sequence with the treatment and with the results from the bars. Liability to crack in hardening was greatly reduced when sufficient time was allowed for the heat treatment. Within a certain range of temperature cutters which broke badly in hardening were generally made from blanks in which the ratio of the Brinell hardness number to the Shore figure was comparatively high. It was found that specific heat treatments can be given which ensure a minimum change in length after hardening. The modulus of elasticity of the hardened bars, which differed greatly in other respects, remained remarkably uniform. A standard hardening test is suggested which would give a recognised standard of hardening behaviour. —T. H. Bu.

Tungsten steels; Use of very slow cooling in the micrographic study of alloys and the structure of ——. A. Portevin. Comptes rend., 1921, 172, 964—967.

BY very slow cooling it is possible to get an enlargement of the whole structural design in alloys in chemical equilibrium, thereby facilitating their micrographical examination; to realise a state of equilibrium or a state nearer to this latter in the case of alloys showing constituents of tempering; to obtain evidence of states not in equilibrium; which have hitherto only been indicated by new equilibrium structures. By the application of this method to tungsten steels containing 0·1—0·4% C and 5—7·5% W, after a reheating to 1300° C. and cooling to 200° C. in 75 hrs. it is possible to obtain a structure with four constituents comprising a ferrite with tungsten, a tungsten carbide, a troostite with tungsten, and a new constituent, a complex of ferrite+Fe_2W.—W. G.

Rusting experiments with sheet iron containing copper. O. Bauer. Stahl u. Eisen, 1921, 41, 37—45, 76—83.

Two series of experiments were carried out with iron sheets containing increasing percentages (0·09—0·46) of copper. In the first series large sheets were used with the annealing or rolling skin unbroken. The influence of the copper is only plainly marked in industrial districts where iron high in copper corrodes less readily than iron poor in copper. In pure air or in sea air slight additions of copper have in general little effect. This also applies to rusting tests carried out in sea water and on buried material. In the second series of experiments the sheets were small and were without an annealing or rolling skin. With sheets of this nature the results obtained in pure air were not distinct nor reliable, and in distilled water, tap water, or North Sea water the varying percentages of copper were without effect. In water containing much carbon dioxide in solution copper slightly reduced the rusting. Small copper additions also protected against attack by sulphuric acid, and partly counteracted the influence of high percentages of phosphorus.—J. W. D.

Iron and steel; Corrosion of ——. T. S. Fuller. Trans. Amer. Electrochem. Soc., 1921, 337—346. [Advance copy.]

RELATIVE rates of corrosion of iron were determined by observing the formation of rust caused by a single drop of water placed on a roughly polished surface of the metal. Results of oxidation are perceptible in 1 min. and well marked in 15 mins. By applying successive drops on the same spot, after complete evaporation of a previous drop, the initial rate of corrosion was shown to be much greater than that of later action. Zinc inhibited corrosion in its immediate vicinity, but the zinc itself was attacked. Small quantities of aluminium and calcium did not change the initial rate of corrosion, but chromium produced a marked effect. Copper steels proved to be more resistant to corrosion than cold-rolled wrought iron.—C. A. K.

Iron; Protection of —— *with paint against atmospheric corrosion.* J. N. Friend. Iron and Steel Inst., May, 1921. [Advance proof.] 4 pages.

A CONTINUATION of previous work (J., 1918, 736 A). Plates of open-hearth steel, cold-rolled, charcoal annealed, and eventually polished, were painted, left exposed to the air for 5 years, cleaned, and the loss in weight determined. Ordinary boiled oils do not offer so good a protection as litho oils owing to the catalyst (drier) accelerating disintegration of the paint film. The best results are obtained by giving the iron first a coat of low pigment content followed by a coat of high pigment and low oil content. The first film then clings tenaciously to the surface of the metal, while the outer coat protects the inner owing to its lower permeability by moisture and greater resistance to mechanical erosion. —A. R. P.

Brasses containing tin; Quenching of ——. L. Guillet. Comptes rend., 1921, 172, 1038—1041.

THE mechanical properties of brasses containing tin are considerably improved when the percentage of

tin is sufficiently high for the formation of the special constituent, similar to the δ-constituent of bronzes (*cf.* J., 1906, 813), if the conditions of quenching are such that this constituent goes into solution. Thermal anomalies appear with this special constituent, which shows the same transformation as the δ-constituent of bronzes. This constituent dissolves at 350° C. in the β-constituent of brass. Quenching at 600° C. considerably improves alloys containing this constituent, there being a marked increase in their breaking strain, resilience, and hardness.—W. G.

Arsenic; Removal of —— from zinc electrolyte by means of hydrogen sulphide. H. R. Hanley. Chem. and Met. Eng., 1921, 24, 693—696.

A plant for the safe generation on a technical scale of hydrogen sulphide and its employment for the precipitation of arsenic from a solution of arsenical zinc fume in sulphuric acid is described, consisting of a rotating horizontal cylindrical generator, charged with a low-grade copper matte and about 75% (of the weight of matte) of sulphuric acid in 20% dilution, and connected through its end trunnions with the precipitating tank by pipes forming a completely closed circulatory system through which the gases are propelled by means of Roots blowers, the attenuated gas after passing through the arsenical solution being returned to the generator. The gas is delivered to the precipitating tank through a perforated coil situated midway up the tank, whilst a portion of the attenuated gas is injected into the bottom of the tank by a second blower in order to keep the liquid in agitation, and prevent the precipitation of zinc sulphide by a local excess of hydrogen sulphide. The last traces of arsenic are removed by precipitation as an iron arsenic compound, as complete removal by hydrogen sulphide would cause co-precipitation of zinc. The arsenic solution is given a preliminary treatment with sulphur dioxide to reduce arsenates if present, before the hydrogen sulphide treatment.—G. F. M.

Sintering process; Investigation of the ——. K. Endell. Metall u. Erz, 1921, 18, 163—177.

In the making of agglomerates for smelting from finely divided ores, flue dust, and other residues, the aim should be to produce a body which is porous and mechanically strong at 1000° C., has the greatest possible surface, and requires the minimum of fuel in the subsequent smelting process. Sintering of the mass is usually brought about either by an increase in the grain size of one or more of the constituents with consequent intercrystallisation of the particles, in most cases accompanied by an increase in the specific gravity, or by reactions between the solid constituents of the mass resulting in an evolution of heat and partial fusion of the particles, or in the formation throughout the mass of interlocked crystals of a new compound. The course of the changes that take place during sintering may be followed by the construction of a heating curve and by direct observation through a microscope in conjunction with a small electric heating furnace fitted with a thermo-couple. Such an instrument is described in the paper in detail, together with some results obtained by its use. —A. R. P.

Blast-furnace and cupola slags. Their composition and graphic methods for determining their constitution. J. E. Fletcher. Iron and Steel Inst., May, 1921. [Advance proof.] 20 pages.

The author's investigations support the view that blast-furnace slags consist of a solvent silicate of $2RO,SiO_2$ type in which the remaining constituents are dissolved. A clear view of the theory is provided by means of graphic methods. Alumina lowers the fusion temperature, affects the viscosity of the silicate in which it is dissolved, and behaves as a neutral constituent. The free silica is the active agent in siliconising the hearth metal. The metasilicates when superheated above their melting point become orthosilicate in character, the amount of superheating needed being reduced in the presence of alumina and ferric oxide. The composition of the primary slags is of fundamental importance. Though the mineralogical character of cold slags affords useful information, it is necessary to ascertain the most probable composition of the liquid slags at the time the reactions are in progress. As the alumina content in blast-furnace slags increases, the silica activity decreases. As the lime content of cupola slags increases, their character approaches that of blast-furnace slags.—T. H. Bu.

Blast-furnace gas; Cleaning of ——. S. H. Fowles. Iron and Steel Inst., May, 1921. [Advance proof.] 21 pages.

The use of blast-furnace gas for boiler firing shows only 20% efficiency as compared with its use in large gas engines, and the problem of the most efficient use of blast-furnace gas (*i.e.*, in internal combustion engines) rests largely on a satisfactory gas cleaning process. Internal wet cooling of the gas is condemned because of the loss of potash, and because the dew point of the gas is raised, necessitating a higher degree of preheating of the gas before entering the bag chamber to avoid deposition of moisture. In a plant erected by Palmers' Shipbuilding and Iron Co. the crude gas passes through dry coolers through which pass four vertical annular tubes. Water sprays in the inner tubes effected a temperature fall of 40°—45° C., but good results are obtained by forced air cooling. The gas then passes through the preheaters and filter-bags, the whole of this system being under suction, as more rapid cooling and dust separation were effected under this condition than when the cleaning plant was under pressure. The temperature at the filter-bags should not be below the dew point of the gas. The ideal condition to be aimed at is to cool the gas externally, before cleaning, to a point approaching a dew point of 15°—25° C., as the cleaned gas would then be directly available for use in a gas engine. The electrostatic type of cleaner allows the sensible heat of the gas to be retained, but the gas is not sufficiently freed from dust for use in gas engines and the power costs are high. Operating details of the plant are given in an appendix.—C. A. K.

Patents.

Furnaces [; Reverberatory ——]. J. L. Gal. E.P. 122,395, 19.9.18. Conv., 12.1.18.

The roof of a reverberatory furnace is of parabolic or other suitable geometrical form and arranged so that the material to be heated receives the whole of the reflected heat rays from the fire-hearth or other source of heat. In contact with, or spaced from, the interior of the crown is a covering of trellis work coated with material of high absorptive and emissive power such as cerium oxide, and the exterior may be similarly covered with material of low emissive power, such as copper sheet. The trellis work may be heated directly by Bunsen burners.—B. M. V.

Furnaces; Heating device for —— particularly applicable to furnaces for the melting of steel and other metals. A. Festa. E.P. 147,190, 7.7.20. Conv., 7.12.18.

In a reversible furnace fired with liquid fuel, the fuel is ignited (and partially distilled) on trays in a

chamber at the end of the furnace. Air required for the combustion of the fuel, after passing through a hot regenerator, is conveyed through a flue close to the chamber containing the fuel trays, and meets the products of partial combustion after entering the furnace chamber.—C. A. K.

Solder for aluminium and other metals. P. A. Agostini. E.P. 156,665, 6.1.21. Conv., 5.1.20.

A SOLDER particularly suitable for soldering aluminium to copper or to another piece of aluminium contains at least 50% of zinc, together with tin, copper, and aluminium, preferably in the proportions, 30—35% Sn, 1—2% Cu, 12—15% Al, and 50—53% Zn.—A. R. P.

Pre-leaching apparatus for use in the treatment of calcined ore and the like. E. C. Vigeon and J. McConway. E.P. 161,375, 6.2.20.

DRY ore or the like on its way from the roaster is sprinkled with a liquid while in a conveyor, preferably of the screw type.—B. M. V.

Tin scrap; Method of obtaining iron and tin from ——. P. A. Mackay. E.P. 161,654, 9.1.20.

TIN is removed from tin scrap, leaving bright iron, by immersing the scrap in diluted oleum, the concentration of free sulphur trioxide being maintained at about 10%. The temperature is preferably kept at 45°—50° C.—C. A. K.

Gold-separator; Electrochemical ——. H. P. Ewell. U.S.P. 1,374,370, 12.4.21. Appl., 7.11.18.

THE apparatus consists of an amalgamating chamber into which the ore is continually fed by mechanical means and a second chamber in which liquid sodium amalgam is formed, and from which it is fed continuously into the amalgamating chamber. The whole charge passes from the latter to a shaking pan, where the amalgam is drained off from the tailings and passed to a device where it is treated to remove the excess of mercury from the gold amalgam. The recovered mercury is returned to the chamber in which the sodium amalgam is made.—A. R. P.

Ore; Process of treating ——. C. G. Collins, Assr. to C. A. Stevens. U.S.P. 1,374,434, 12.4.21. Appl., 13.1.20.

ORE is heated to expel, and treated so as to prevent the re-entry of, air and moisture. The ore is then concentrated.—C. A. K.

Treating liquids with gases; Apparatus for ——. *Flotation apparatus.* W. E. Greenawalt. U.S.P. (A) 1,374,445, (B) 1,374,446, (C) 1,374,447, (D) 1,374,499, and (E) 1,374,500, 12.4.21. Appl., (A) 4.11.19, (B) 16.10.19, (C) 26.5.16, (D) 27.12.15, and (E) 30.10.15. Renewed (B) 25.5.20, (C) 22.3.20, (E) 12.2.20.

(A) A TANK is fitted with a rotary atomiser mounted on a vertical shaft. Liquid in the tank is caused to flow to the centre of the atomiser, and the gas and liquid are mixed and ejected together through outlet holes arranged radially in the atomiser. (B) Gas is passed through a hollow shaft and rotary atomiser into the liquid in the tank. (C) A vertical shaft suspended in a tank is provided with a number of perforated discs which rotate between similar fixed discs. Gas is introduced into the bottom of the tank and is atomised by rising through the series of discs. (D) A hollow member on a vertical shaft rotates in close proximity to stationary baffles, and an electric current is passed from the rotating to the fixed parts. (E) Gas may be passed through a hollow shaft and into a hollow rotating member under the liquid. The drum is provided with radial outlets for the gas.—C. A. K.

Electrolytic process [for copper deposition]. F. S. Woodward. U.S.P. 1,374,541, 12.4.21. Appl., 25.7.19.

COPPER is deposited from an acid bath, using an insoluble anode, and in restoring the bath to normal strength the resulting increase of acidity only is neutralised.—J. S. G. T.

Pickling process. J. Coulson, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. 1,374,552, 12.4.21. Appl., 8.10.17.

A FERROUS metal is pickled by subjecting it to the action of an electric current in the presence of an electrolyte containing sulphuric acid, the polarity of the metal being reversed during the process. —A. G.

Electromagnetic separator. Maschinenbauanstalt Humboldt. G.P. 330,641, 7.8.19.

THE separator consists of two magnets one above the other, with a magnetic roller in between. The lower magnet, between which and the roller the material to be separated is passed, is provided with one or more openings beneath the middle of the roller, through which the non-magnetic material falls, while the magnetic part is carried over the far end of the lower magnet by the action of the roller.—A. R. P.

Zinc and tin; Process for electro-plating metals with ——. Deutsche Metallveredlungs-G.m.b.H. G.P. 305,583, 22.4.17.

BY depositing zinc or tin from baths of 4°—5° B. (sp. gr. 1·03—1·04) with a low current density (not greater than 2·5 amps. per sq. dm. of cathode area), very thin, strongly adherent, firm coatings of metal may be obtained.—A. R. P.

Alloys containing graphite; Manufacture of ——. G. H. Wichmann. G.P. 332,914, 16.5.20.

THE granulated alloy is given a coating of graphite and then cast or pressed into the required shape. The graphite remains evenly distributed throughout the metal, which is suitable for use in stuffing-boxes or bearings.—A. R. P.

Precious metals; Recovery of —— from sea-water. Siemens und Halske A.-G. G.P. 333,758, 17.8.18.

SEA-WATER is passed through absorption filters, preferably of fine-grained charcoal, which are cathodically polarised by the use of small currents of a few milliampères.—A. R. P.

Steel. P. MacGregor and A. Balfour. U.S.P. 1,375,255, 19.4.21. Appl., 18.9.18.

SEE E.P. 129,330 of 1917; J., 1919, 685 A.

Metals; Process of separating and refining ——. G. Haglund. U.S.P. 1,375,631, 19.4.21. Appl., 5.12.18.

SEE E.P. 121,591 of 1918; J., 1919, 908 A.

Blast furnaces, gas generators, and the like; Automatic charging apparatus for ——. Eisenwerk Jagstfeld Ges. E.P. 145,539, 22.6.20. Conv., 22.4.18.

Ore sintering mechanisms. R. J. Tugwood. From Dwight and Lloyd Metallurgical Co. E.P. 161,491, 7.8.20.

See also pages (A) 375, *Asbestos cloth* (E.P. 153,558). 388, *Blast-furnace slag* (E.P. 139,172). 389, *Ore flotation* (U.S.P. 1,359,037). 396, *Ferromanganese* (U.S.P. 1,361,036).

XI.—ELECTRO-CHEMISTRY.

Water; Electrolysis of ——, and an oxyhydrogen gas element. E. Baur. Helv. Chim. Acta, 1921, **4**, 325—333.

With the object of storing seasonal water-power, the author has devised an apparatus by means of which fused aqueous sodium hydroxide is subjected to electrolysis, sheet-iron electrodes being employed. When the electrolysis is interrupted, the cathodes generate hydrogen and undergo corrosion, but this does not occur when the apparatus is at work. The purity of the hydrogen and oxygen formed is about 99% and the current yield over 90%. Only the hydrogen is stored and is used subsequently in conjunction with air in an element in which electric current is produced by the union of the hydrogen and oxygen in contact with fused sodium hydroxide, iron electrodes in the form of grids being employed. —T. H. P.

Patents.

Gas battery. P. A. Emanuel. U.S.P. 1,359,881, 23.11.20. Appl., 15.5.20.

In a cell provided with electrodes of coiled iron wire coated with iron oxide and asbestos and separated by an asbestos diaphragm and connected respectively with supplies of hydrogen and oxygen, a jet of air under pressure is directed downwards into the centre of the cell towards a vent and by its injector action removes the water which would otherwise collect in the bottom of the cylindrical cell casing.

Ferromanganese [anodes]; Casting ——. C. G. Fink, Assr. to Chile Exploration Co. U.S.P. 1,361,036, 7.12.20. Appl., 9.7.19.

Ferromanganese (78—82% Mn) can be cast in the form of thin plates, free from checks or cracks, and possessing satisfactory mechanical strength for use as anodes in electrolytic processes, if a small quantity of a scavenger, *e.g.*, 3% of aluminium or magnesium, be added to it.

XII.—FATS; OILS; WAXES.

Kapok seed; Indian —— as a source of oil. Bull. Imp. Inst., 1920, **18**, 335—337.

Indian kapok (*Bombax malabaricum*) yielded on extraction with petroleum ether 22·3% of a bright yellow oil, which deposited a quantity of "stearin" on standing, and had $n_D^{40}=1·461$. The yield of oil is higher than that generally obtained from other kapok seed, and the oil appears to be of better quality. The material left after the extraction of the oil contains about 36% of crude proteins. —J. C. K.

Oil from Cynara cardunculus. E. H. Ducloux. Anal. Soc. Quim. Argentina, 1920, **8**, 410—412.

The oil extracted from the seeds of the "donkey thistle" (*Cynara cardunculus*), a troublesome weed in South America, is deep yellow in colour, tasteless, and aromatic in odour. It has sp. gr. 0·9213 at 15° C.; $n_D^{20}=1·4729$; $n_D^{15}=1·4712$; iodine value, 103·5; saponif. value, 197·4; insoluble fatty acids, 95·6%; acid value, 39·8; solidif. pt. of fatty acids 29° C. Its properties are similar in many respects to those of cottonseed oil.—G. W. R.

Acetyl value of fatty substances; Determination of the ——. É. André. Comptes rend., 1921, **172**, 984—986.

The saponification value of the material is determined before and after acetylation. These values being S and S_1 respectively, then the acetyl value equals $S_1-S[1+\lambda S/(1-\lambda S)]$, where $\lambda=0·75$. The values obtained by this method are always slightly lower than those obtained by the method of Lewkowitsch (*cf.* J., 1890, 660; 1897, 503).—W. G.

Decolorising agents for the fat industries. J. Zifferer. Oel- u. Fettind., 1920, **2**, 63—64, 87—88, 112—113, 134, 160, 183—184. Chem. Zentr., 1921, **92**, II., 861—862.

The only suitable carbons are those made from materials which do not fuse on charring; hence proteins, glue, etc. give the best products when carbonised with potassium carbonate or sodium potassium carbonate. Carbons containing nitrogen are more active than those containing none. In diminishing order of activity the chief carbons are: animal charcoal from ferrocyanide residues, blood charcoal, bone charcoal, glue charcoal, soot, wood charcoal, and sugar charcoal. Nodules of the size of peas should be used for aqueous solutions, but for oils finely ground carbon is best. For the fat industry bone char is of much less importance than charcoal from ferrocyanide manufacture; the latter cannot be revivified. Florida fuller's earth (*floridin*) is active in the air-dry state at 18° C., but more so at 120° C. or when dehydrated at 300°—400° C. The oil is treated with 2—5% and warmed. The earth can be revivified by various methods, but it recovers only two-thirds of its original activity. Salad oils decolorised by silicates often have a slight rancid flavour, and for this reason sodium bicarbonate is frequently added. An earthy flavour is eliminated by washing with 10% brine.—J. H. L.

Oxidised fatty acids in olive oils obtained by extraction with carbon bisulphide; Determination of ——. F. Goldschmidt and G. Weiss. Seifenfabr., 1920, **40**, 649. Chem. Zentr., 1921, **92**, II., 815—816.

Contrary to Stadlinger's results (J., 1920, 663 A), the authors obtained practically the same values for the oxidised fatty acids in three samples of olive oil high in oxidised acids obtained by extraction with carbon bisulphide, when using different samples of petroleum spirit, including one containing 4% of xylol.—A. de W.

Fats; Influence of light on animal and vegetable ——. H. Much and H. Schmidt. Z. Immunitätsforsch. Exp. Ther., 1920, **31**, 169—200. Chem. Zentr., 1921, **92**, I., 645.

The colour of animal and vegetable fats is destroyed by the combined action of light and oxygen; light of short wave-length has the most effect. If the

fats are dissolved in solvents, the effect of light is least in an ethereal solution and greatest in a carbon tetrachloride solution. It is possible that the colour of animal fats is derived from carotin-like substances present in the food of the animals. —W. P. S.

C_{18} fatty acids. I. Non-identity of elæostearic acid tetrabromide from tung oil with ordinary linolic acid tetrabromide. B. H. Nicolet. J. Amer. Chem. Soc., 1921, **43**, 938—940.

Contrary to the views of Kametaka (J., 1903, 1138), it is shown that the tetrabromide obtained from α-elæostearic acid isolated from tung oil is not identical with linolic acid tetrabromide. It is identical with β-elæostearic acid tetrabromide (Morrell, J., 1912, 1189). (*Cf.* J.C.S., June.) —W. G.

Hydrogenation of oils; New catalyst for ——. G. Grote. Seifensieder-Zeit., 1920, **47**, 713—714. Chem. Zentr., 1921, **92**, II., 812.

A catalyst, with which the time of hydrogenation can be reduced to 10—15 mins. and the temperature to 160° C., is prepared by treating an aqueous solution of a nickel salt with a solution of a magnesium or aluminium salt so as to obtain a colloidal precipitate (double silicate) containing the whole of the nickel and magnesium or aluminium. The voluminous gelatinous precipitate is washed, dried, powdered, and heated in a stream of hydrogen, and the dark-grey reduction product stored in oil.—A. de W.

Beeswax; Detection of very small quantities of —— in admixture with mineral oil and colophony. A. Jolles. Oel- u. Fettind., 1920, **2**, 207, 231—232. Chem. Zentr., 1921, **92**, II., 862.

Comparative experiments were made with mixtures of which one contained 70% of colophony and 30% of mineral oil and the other 67% of colophony, 30% of mineral oil, and 3% of yellow beeswax. The saponification values of the original mixtures proved useless for the detection of beeswax. By extraction with cold 70% alcohol, however, the colophony was removed, and the residue in the case of the wax-free mixture gave saponification and acid values of practically 0, whilst in the other case the saponification value was 8·41, the acid value 1·70, and the Hübl iodine value 3·94, the calculated values being 8·46, 1·80, and 3·67 respectively. It was found possible to separate the wax from the mineral oil by means of petroleum ether, in which the former is insoluble.—J. H. L.

Carnauba wax palm; Utilisation of the ——. C. Grimme. Pharm. Zentralh., 1921, **62**, 249—257.

The S. American carnauba wax palm (*Copernicia cerifera* Mart.) yields an edible fruit containing about 10% of oil, the greater part of which is found in the seeds; the roots of the tree are stated to have certain medicinal properties, the trunk consists of a very hard wood, and the leaves are useful for a variety of purposes (thatching, paper-making, thread making, etc.). The young green leaves are edible, and from them exudes the well-known carnauba wax.—W. P. S.

Hydrogenated phenols and their use in the soap industry. W. Schrauth. Seifenfabr., 1921, **41**, 129—132. Chem. Zentr., 1921, **92**, II., 814.

The mixture of cyclohexanol and the three isomeric methylcyclohexanols, known under the trade name of "hexalin," is used as a substitute for castor oil products hitherto used in technical soaps. In spite of its small solubility in water and its oily nature, hexalin yields clear permanent solutions with aqueous soaps, even when present in an amount substantially in excess of the soap. A suitable mixture consists of oleic acid, 500 kg., alkaline lye (50° B., sp. gr. 1·53) 200 kg., hexalin 600 kg., water 400 kg. Special advantages are claimed for hexalin soap mixtures in wool-scouring, chemical cleaning, emulsification, and in the preparation of cutting oils, shoe creams, plant sprays, etc.—A. de W.

Glycerin; Viscosity of distilled ——. J. Kellner. Z. deuts. Oel- u. Fettind., 1920, **40**, 677—678. Chem. Zentr., 1921, **92**, II., 834.

The viscosity of a crude glycerin distillate, with an ash content of 0·001% and sp. gr. 1·24 at 15° C., was reduced by the refining process from 35·5° Engler to only 16·75° at 24° C. The latter value corresponds with an almost chemically pure glycerin, according to tables given in the paper. Viscosity measurement is recommended therefore as a valuable test of the purity of glycerin.—B. V. S.

Wax-colophony mixtures. Jahn. *See* XIII.

Influence of fats on growth of bacteria. Much and Schmidt. *See* XVIII.

Patents.

Oils and fats; Process of refining ——. K. Stiansen. E.P. 141,028, 9.3.20. Conv., 21.3.19.

Oil, *e.g.*, whale or herring oil, is agitated at 40°—50° C. with about 5% of its weight of powdered, calcined apatite or other mineral phosphate, and is subsequently allowed to stand at the same temperature, whereby the apatite settles to the bottom together with impurities present in the oil. Solid fats are treated at a temperature sufficiently high to render them fluid.—L. A. C.

Animal and vegetable oils; Refining and decolorising ——. A. S. Quick. E.P. 161,813, 20.3.20.

To every 20 galls. of the oil an equal quantity of water and 10 lb. of monazite sand or other radioactive material are added, the mixture is heated to a temperature below that at which it is chemically altered, *e.g.*, about 120° F. (49° C.), and stirred continuously for about 6 hrs., allowed to settle, and the oil separated.—A. de W.

Fatty acids and glycerides thereof; Process of treating [dehydrogenating] ——. H. A. Levey. U.S.P. 1,374,589, 12.4.21. Appl., 19.9.16.

Fatty oils are dehydrogenated by subjecting them to the action of a gas when mixed with catalytic material at a temperature in excess of that at which hydrogenation is effected under the same conditions by passage of hydrogen.—A. de W.

Sulphated oil. F. L. Randel. U.S.P. 1,374,607, 12.4.21. Appl., 11.12.19.

A fatty or oily material is mixed with sulphuric acid *in vacuo*.—A. de W.

Fats; Apparatus for the extraction of —— from moist, granular, or powdery materials. A. Lorenz. G.P. (A) 333,492 and (B) 333,493, 25.7.17.

(A) The cover of the extraction vessel slopes steeply from one side to the other and is pierced in the centre by the shaft of the agitator. The solvent containing the fats is withdrawn through the highest part of the cover, and the outlet is fixed on one side of the agitator, which is driven from the top. The pulley is attached on the low side of the cover. (B) The closed extraction vessel has a perforated bottom, beneath which the solvent is admitted. At the side of the vessel a box is attached containing a group of valves, arranged one above another, each of them being preceded by a filter. The valves are connected with the outlet, allowing the solvent to be withdrawn from the vessel, after the extraction is completed, without coming in contact with the atmosphere.—C. A. C.

Glycerin; Process for purifying ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 146,865, 5.7.20. Conv., 17.1.19.

CRUDE glycerin is freed from electrically-active impurities, *e.g.*, inorganic salts, fatty acids, soaps, fat, protein, colouring matters, and the like, largely present in the colloidal state, by electro-osmosis, using diaphragms of marked electric potential and carrying a suitable charge to induce passage of the impurities through the diaphragms. Thus, crude glycerin is freed from accompanying acid (negatively charged) impurities by subjecting it, preferably at raised temperature, to an electric current when contained in the cathode chamber of a cell divided into two compartments by a positive diaphragm, such as leather, the acid impurities migrating to the anode chamber which contains water. Similarly, basic impurities migrate to the water contained in the cathode chamber of a cell divided into two compartments by a vegetable (viscose or parchment paper) diaphragm, when the crude glycerin is contained in the anode chamber. The crude glycerin may also be contained in the middle chamber of a three-part cell, the two separating diaphragms of which may be either of negative or of a positive character, or that bounding the cathode chamber of negative or indifferent character, while that bounding the anode chamber is of positive character, the electrodes being in the side cells which contain water.—A. de W.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Smalt; Constitution of ——. A. Duboin. Comptes rend., 1921, 172, 972—974.

USING the method previously described (*cf.* Comptes rend., 1892, 114, 1361) the author has produced two blue cobalt compounds of the type of smalt. One has the constitution K_2O, CoO, $3SiO_2$, and the other KCl,K_2O,CoO,$4SiO_2$.—W. G.

Turpentine; Composition of French ——. M. Vèzes. Comptes rend., 1921, 172, 977—980.

THE results obtained by the polarimetric method of Darmois (Thesis, Paris, 1911) for the estimation of the relative amounts of pinene and nopinene present in French turpentines can only be considered as first approximations. Further work is necessary to elucidate the discrepancies found. —W. G.

Turpentine oil; Determination of petroleum spirit in ——. J. Marcusson. Chem.-Zeit., 1921, 45, 418.

REPLYING to recent criticism by Salvaterra (J., 1921, 186 A), the author maintains the accuracy of a method described previously by himself (J., 1912, 444) and depending on the conversion of the turpentine oil into soluble oxidation products by means of fuming nitric acid.—W. P. S.

Phenols of low-temperature coal tar [; *Resins from* ——]. W. Gluud and P. K. Breuer. Ges. Abhandl. Kennt. Kohle, 1919, 4, 221—236. Chem. Zentr., 1921, 92, II., 855—856.

AN investigation was carried out to determine what proportion of the total phenols in low-temperature coal tar could be utilised in the production of "bakelite" and "novolac" by condensation with formaldehyde. The action of the latter in the presence of ammonium chloride as catalyst was tested on the following products: Crude tar from which the most viscous compounds had been removed, the fractions distilling between 150° and 250° C. and between 250° and 300° C., including the hydrocarbons that distil at these temperatures, the cresol fraction, and the phenols obtained from the lubricating oil and resinous fractions. The hydrocarbons present did not interfere with the reactions and could readily be removed from the products, which were solid, brittle resins having the properties of the "novolacs." Condensation of a crude tar-cresol mixture with benzaldehyde and paraldehyde yielded viscous semi-solid products which could be changed into solid resins by heating under pressure. The colour of the resins varied, according to the material from which they were produced, from light yellow to dark brown, and they could be made less brittle by leaving behind in the final product a certain amount of the hydrocarbons originally present in the raw material. Bakelites A (soluble), B (fusible), and C (infusible) were prepared by condensation in the presence of a basic catalyst such as ammonia, but variety A can only be made from the whole of the phenol fraction of the crude tar or from the whole of the crude tar itself. The bakelites are clear solid substances varying in colour from light yellow to very dark brown, and the A variety yields good varnishes in 50% alcoholic solution. Variety C may be made from A by the use of benzylamine as a catalyst, or it may be produced directly from the phenol fraction boiling below 230° C. or from that boiling between 230° and 260° C. if soda is used as a catalyst. —A. R. P.

Lead compounds of phenols; Use of —— [*in paints*]. F. Fischer and V. Ehrhardt. Ges. Abhandl. Kennt. Kohle, 1919, 4, 264—279. Chem. Zentr., 1920, 92, II., 854.

LEAD oxide combines with phenol, cresol, *p*-hydroxydiphenyl, and naphthols in benzene solution to give products which are not very satisfactory as paints. If, however, instead of the pure phenols the crude phenol-rich fraction (middle oil) of low-temperature tar or coke-oven tar is used, the product is a useful paint for protecting iron-work from rust. The difference in the two products is ascribed to the action of the resinous substances produced from the easily oxidisable hydrocarbons in the crude oils by the action of the lead oxide. Oxidation of the crude tar oils and distillation with potassium permanganate or nitric acid yields varnish-like substances.—A. R. P.

Wax and colophony; Supersaturated solid solutions of ——. G. Jahn. Kolloid-Chem. Beih., 1921, 13, 213—232.

MIXTURES of beeswax and colophony can be divided into liquid mixtures, solid solutions, and mixtures in which solid solutions are in equilibrium with pure wax. Mixtures containing up to 75% of colophony can form solid solutions, and on melting and rapidly cooling, supersaturated solutions are formed which are more stable the longer the mixture has been kept in the liquid condition. (*Cf.* J. C. S., June.)—J. F. S.

Protection of iron. Friend. *See* X.

Patents.

Resin-like bodies; Production of ——. M. Melamid. E.P. (A) 133,712 and (B) 133,713, 11.10.19. Conv., 4.2.18.

(A) Resin-like substances are obtained by treating aromatic sulphochlorides with salts of resinic, humic, or lignoceric acids; *e.g.*, to a solution of 120 kg. of sodium colophonate in 100—200 kg. of water is added 100 kg. of α- or β-naphthalene-sulphochloride with stirring, the solution being heated to 30° C. for 12 hrs. The liquid is allowed to cool, and the solid product separated by decantation or filtration, and dissolved for the purpose of purification in an organic solvent, *e.g.*, benzol, which is then evaporated off. (B) The resinates or the like are replaced by soft coal-tar pitch, anthracene oil distillates obtained in the production of hard pitch therefrom, or the alkali-soluble phenolic portion of soft pitch or anthracene oil, in the presence of alkali; *e.g.*, 100 kg. of soft pitch containing 20% of alkali-soluble matter, is heated with sufficient caustic soda lye to neutralise the acidity, allowed to cool while stirring constantly, and about 24 kg. of *o*- or *p*-toluenesulphochloride (or a commercial mixture of the same) in benzol added. After stirring for 12 hrs., the benzol solution is separated from the aqueous layer, washed with water until neutral, dried over, *e.g.*, calcium chloride, and the solvent distilled off *in vacuo*.—A. de W.

Anti-corrosive paint or composition. C. H. Ivinson and G. S. Roberts. E.P. 161,201, 12.7.19.

To a solution of asphaltum in a volatile solvent, *e.g.*, 6 lb. to 0·75 gall. of benzol or petrol, is added 2—5% of a solution of rubber in benzol or other solvent, of a strength of, *e.g.*, 2 oz. to 40 oz. of solvent; preferably a similar amount of a solution of 4 oz. of gum elemi in 2—6 oz. of solvent is also added. The mixture is treated with 1—4% of sulphur, sulphur monochloride, or sulphides such as antimony sulphide, and vulcanised by heating to about 95° F. (35° C.) for about 30 mins. The composition, when cooled, is ready for use, or suitable filling agents such as silica, asbestos, graphite or the like may be added. Metallic stearates, palmitates, oleates, or resinates dissolved in a volatile solvent may be employed in place of the solution of gum elemi. Alternatively, 0·5—1% of sulphur or a suitable sulphide may be added direct to the molten mixture of asphaltum and rubber, the vulcanised composition being then dissolved in a hot solvent.—A. de W.

Pigments; Process of making ——. L. R. Baker. E.P. 161,280, 6.1.20.

A solution of commercial zinc sulphate is heated by live steam and blown with compressed air, during which time about 1% by wt. of an alkaline-earth peroxide, *e.g.*, calcium or barium peroxide, and powdered zinc or lead oxide are added. After filter-pressing to remove precipitated iron oxide, the filtrate containing hydrated zinc oxide in suspension is again treated with steam and compressed air, and subjected to another filter-pressing operation. The filtrate is then mixed with a solution of barium sulphide in equivalent amount, the resulting precipitate being filter-pressed, washed, dried, calcined, etc.—A. de W.

Strontium and barium sulphates; Method of obtaining —— *from native sulphates.* P. A. Mackay. E.P. 161,655, 9.1.20.

Native strontium or barium sulphate ground to pass a 200-mesh sieve is dissolved in oleum and re-precipitated by dilution. The resulting *blanc-fixe* is superior in colour and fineness to that prepared by grinding and levigation.—C. I.

Coating composition and process of producing same. W. Alexander and J. E. Clegg. U.S.P. 1,358,914, 16.11.20. Appl., 25.9.17.

A liquid coating composition is composed of a cellulose ester (pyroxylin, celluloid) and a boron compound (dehydrated boric acid) dissolved in a common solvent, *e.g.*, methyl ethyl ketone, which is saturated with the boron compound.

Finely-divided material [carbon black]; Process of cleansing ——. J. C. Morrell. U.S.P. 1,359,091, 16.11.20. Appl., 22.3.19.

Volatile impurities, *e.g.*, adsorbed hydrocarbon oils, are removed from carbon black by heating it to 450°—600° C. in an iron crucible having a perforated false bottom and treating it with superheated steam introduced beneath the false bottom. The process is applicable to the purification of other finely divided materials, *e.g.*, kieselguhr.

Phenolic condensation product; Process of producing a ——. L. V. Redman, A. J. Weith, and F. P. Brock, Assrs. to Redmanol Chemical Products Co. U.S.P. 1,374,526, 12.4.21. Appl., 16.9.18.

Equal parts of 40% formaldehyde and phenol are boiled together in the absence of a catalyst until a viscous gummy lower layer and a supernatant aqueous layer containing approximately 10% of formaldehyde are formed. The aqueous layer is discarded and the mass shaped and subjected to a prolonged heat treatment below 100° C. until it becomes hard, substantially insoluble, and anhydrous throughout. The mass is then subjected to further heat treatment at a temperature exceeding 100° C. for a relatively short period.—A. de W.

Pitch, colophony, shellac, etc.; Process and apparatus for comminuting materials such as ——. R. Behr. G.P. 333,704, 13.2.18.

A stream of the hot liquefied material is conducted over heated distributing plates or discs from which it flows in very fine threads; the latter are cooled and solidified by falling through the air or by passing through an artificially cooled space. —J. H. L.

Siccatives and binding agents for lacquers and paints. P. Friesenhahn. G.P. 334,761, 25.7.19.

Metallic resinates or linoleates are dissolved in hydrogenised phenols, such as the cyclohexanols or their esters, or in cyclohexanone and its homologues, with or without the aid of other solvents. Solutions of resinates of aluminium, tin, zinc, manganese, and cobalt in cyclohexanyl formate constitute excellent siccatives. The solutions, with or without linseed oil or linseed oil varnish, can be used as vehicles in paints.—J. H. L.

Soot-carbon. E.P. 137,065. *See* IIA.

Lakes. E.P. 143,242. *See* VI.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Hevea rubber; Use of brackish water in the preparation of ——. W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 25, 1—15.

On account of the more thorough washing to which it has been subjected, crêpe rubber is less affected than sheet rubber by the use of brackish water, *e.g.*, tidal river water, for the dilution of the latex. The presence of 12% of sea water in the brackish water is sufficient to produce an appreciable effect on sheet rubber, whereas in the production of crêpe rubber the limiting proportion is about 28%. —D. F. T.

Rubber; Changes in plantation —— after storage. O. de Vries. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 25, 16—28.

STORAGE for 2—4 years in cupboards does not adversely affect the quality of first-grade rubber, and the tensile strength and slope remain unaltered; the rate of vulcanisation generally shows a small increase, but the viscosity frequently decreases considerably. Lower grades of rubber sometimes undergo marked deterioration on storage. Crêpe from "matured" rubber behaved similarly to first-quality crêpe, except that its rate of vulcanisation decreased. Storage therefore tends to lessen the variability in the rate of vulcanisation of plantation rubber.—D. F. T.

PATENTS.

Vulcanisation of rubber. G. Bruni. E.P. 140,387, 4.3.20. Conv., 15.3.19.

IN the presence of a salt of a divalent or trivalent metal with a dithiocarbamic acid derived from a primary or secondary aliphatic amine, *e.g.*, zinc pentamethylenedithiocarbamate, vulcanisation can be effected with as little as from 0·2 to 2% of sulphur.—D. F. T.

India-rubber products; Manufacture of ——. A. Helbronner. E.P. 142,083, 11.2.20. Conv., 19.4.19.

SURFACE resinification in rubber goods vulcanised in an atmosphere of hot air can be avoided by incorporating a reducing agent, such as quinol, pyrogallol, tannins and derivatives, *p*-aminophenol, formaldehyde derivatives, sulphites, or hydrosulphites. Litharge is commonly used for a similar purpose, but causes the development of a black colour which is avoided with the preceding substances.—D. F. T.

Rubber products; Manufacture of ——. H. Wade. From Goodyear Tire and Rubber Co. E.P. (A) 161,482 and (B) 161,483, 6.7.20.

(A) AIR-DRIED glue (containing 5—15% of moisture) is introduced into rubber by subjecting a mixture of it with unworked rubber to a milling action in a jacketed container; heat is developed, and the temperature is maintained below 300° F. (about 150° C.) by external cooling. After this operation the cooled mixture needs no further drying, and the remaining compounding ingredients are incorporated in the usual manner. (B) Instead of introducing fine powders, such as carbon black, directly into rubber, the powder is first mixed uniformly into an emulsion of an aqueous jelly or solution of glue with benzene; this mixture is then incorporated into rubber in the usual manner. —D. F. T.

Rubber, ebonite, vulcanite, and the like substances; Reforming or vulcanisation of ——. H. Gare. E.P. 161,648, 9.1.20.

THE heating necessary for the vulcanisation of rubber or the "reforming" of old vulcanised rubber is effected by a hot circulating solution of which the b.p. is a little above the necessary temperature. A solution of calcium chloride in water is convenient, the proportions for a vulcanising temperature being 3½ lb.:1¼ pints (b.p. 270° F., 132° C.), and for reforming, 6lb.:1½ pints (310° F., 154° C.).—D. F. T.

Rubber; Manufacture of products resembling ——. Badische Anilin und Soda Fabrik. G.P. 329,676, 4.5.18.

THE polymerisation of butadiene and its homologues is considerably expedited by the addition of the *polymerisation products obtained in the manner described earlier (F.P. 459,005 of 1913, and Addition thereto*; J., 1913, 1164).—D. F. T.

Rubber; Process of treating ——. J. Porzel, Assr. to Superior Rubber Co. U.S.P. 1,374,231, 12.4.21. Appl., 7.8.18. Renewed 9.10.20.

SEE E.P. 124,887 of 1918; J., 1919, 379 A. Oxygen is excluded during the mixing operation.

Rubber and the like; Methods of and apparatus for mixing or masticating ——. Farrel Foundry and Machine Co., Assees. of D. R. Bowen and C. F. Schnuck. E.P. 137,820 and 158,279, 9.1.20. Conv., 13.1.19.

XV.—LEATHER; BONE; HORN; GLUE.

PATENTS.

Tanning or impregnating materials; Process for ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 143,921, 28.5.20. Conv., 30.11.18.

AFTER a preliminary tannage or impregnation by the electro-osmotic process described in E.P. 19,849 of 1914 (J., 1915, 1020) the hides or skins are completely tanned or impregnated in pits or casks without the aid of an electric current and preferably in strong liquors.—D. W.

Catechin and catechutannic acid; Manufacture of ——. E. H. Bray. From Indian Wood Products Co. E.P. 161,431, 24.3.20.

WOOD of the *Acacia catechu*, *A. sendra*, etc., is disintegrated and heated with water, preferably in closed vessels with a steam pressure up to 30 lb. per sq. in. The extract is evaporated, preferably under reduced pressure, to a sp. gr. of 1·05—1·10, when catechin separates on cooling. On further evaporation under reduced pressure the mother liquors yield catechutannic acid.—D. F. T.

Leather substitute; Process for preparation of a ——. G. Ruth and E. Asser. G.P. 332,866, 13.6.19.

CELLULOSE esters, alone or mixed with esters of naphthenic acids, are incorporated with insoluble metallic naphthenates, such as the aluminium, chromium, iron, and cobalt salts, particularly the aluminium-magnesium salt, and the mixture is treated in the usual way with loading material. —B. V. S.

Hides; Process for tanning —— by means of ferric salts. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 334,004, 27.2.16.

IN the treatment of hides with solutions of ferric salts the formation of basic salts is avoided by the addition of an acid, such as formic acid, to increase the hydrogen ion concentration, or by employing double ferric ammonium salts, which do not readily hydrolyse, or by adding chromium salts which retard hydrolysis of the iron salts. By this means the hides may be rapidly and uniformly permeated by the iron solution. They are subsequently treated with a neutralising agent, such as sodium carbonate, to increase their durability. Good results are also produced by adding oxidation or decomposition products of glucose or other sugars, such as those obtained by treatment with chromium oxide or chromates, or by addition of vegetable tanning agents, to the solution of iron salts.—W. J. W.

Colouring of natural horn; Process for making the —— water-resisting. M. Lambeck. E.P. 154,200, 22.11.20. Conv., 26.9.19.

ARTICLES of natural horn are exposed either before *or after polishing to the action of formaldehyde, its polymers, or substances capable of yielding form*aldehyde.—D. W.

Mixing or agitating lime in tannery pits; Apparatus for ——. F. J. Boys. E.P. 161,362, 28.1.20.

Iron salt for tanning. E.P. 146,214. *See* VII.

XVI.—SOILS; FERTILISERS.

Soils; Amount of unfree water in —— at different moisture contents. G. Bouyoucos. Soil Sci., 1921, **11**, 255—259.

FURTHER experimental evidence is given in support of the view that the amount of water which soils are able to render unfree (*cf.* J., 1921, 231 A) does not vary with the different moisture contents of the soils, but appears to remain constant. This is contrary to the mathematical deductions of Keen (*cf.* J., 1919, 956 A).—W. G.

Soil; Lime requirement and reaction of lime materials with ——. C. J. Schollenberger. Soil Sci., 1921, **11**, 261—276.

EXPERIMENTS were carried out with a nearly pure limestone of high calcium content, in five degrees of fineness, with calcite, magnesite, and dolomite, ground to pass a 100-mesh sieve, with chemically prepared oxides and carbonates of calcium and magnesium, and with two slags, one a dicalcium silicate and the other a blast-furnace slag. These materials were mixed with soil in undrained pots kept at a suitable moisture content and without a crop. The limestone, calcite, and magnesite were similar in behaviour, approximately one half of an application equivalent to 3·1 tons per acre being attacked in 4 weeks and two-thirds in 28 weeks. The dolomite was 50% more resistant than the other materials. Quicklime is more reactive than the precipitated carbonate, although the differences become less marked with time. Chemically prepared magnesium oxide gradually became carbonated, but on the other hand the disappearance of carbonate from an equivalent application of prepared magnesium carbonate was complete within one month. The dicalcium silicate slag reacted with soil as readily as precipitated calcium carbonate, but blast-furnace slag was the least reactive of all the materials tested. Fineness of grinding is of importance, coarsely ground limestone being far less reactive than finely ground limestone. The quantitative relations between bases not residual as carbonate and reductions in lime requirement were found to be reasonably close, a possible consumption of bases by nitrification being considered. Possible sources of error in determining lime requirements, such as manner of preparation of the sample, the temperature, and the time allowed for the determination are considered.—W. G.

Soil; Comparison of the technique recommended by various authors for quantitative bacteriological analysis of ——. Z. N. Wyant. Soil Sci., 1921, **11**, 295—303.

THE author recommends the following procedure for the quantitative bacteriological examination of soils. Not less than 10 g. of soil should be used in making the first dilution, which should be not less than 1:10. The weighed soil, 10 g., should be placed in a graduated flask and sufficient of the diluting liquid added to make up the volume to 100 c.c. If the soil contains a considerable amount of organic matter, it should be triturated in a mortar with a little of the diluting liquid. In making further dilutions or plating, an aliquot portion of the soil must be transferred and subsequent dilutions may well be 1:10. Numbers of micro-organisms (total or otherwise) should be estimated on the basis of soil dried to a constant weight at 100° C. —W. G.

Soils; Analysis of ——. K. A. Vesterberg. Svensk Kem. Tidskr., 1921, **33**, 12—22. Chem. Zentr., 1921, **92**, I., 752.

THE author questions statements to the effect that salts dissolved in the moisture in soils are absorbed by plants at the same rate as the water itself; the roots do not take up the salts etc. in the proportion in which they occur in the soil. As regards the concentration of plant foods in soil moisture which constitutes the minimum requirement of plants, the following quantities are suggested:—P_2O_5, 1—2; nitrogen, 2—5; K_2O, 10—20 mg. per litre. Climate would possibly have some effect on the efficiency of these amounts of foods.—W. P. S.

Soil fumigation experiments with p-dichlorobenzene for the control of the peach-tree borer, Sanninoidea exitiosa, Say. A. Peterson. Soil Sci., 1921, **11**, 305—319.

p-DICHLOROBENZENE gave satisfactory results when used as an insecticide for the control of the peach-tree borer. One ounce of the material is applied to the soil in a circular band round the tree and 2 in. from it, on a level with the highest point where gum is exuding from the tree, which is earthed up if necessary. The *p*-dichlorobenzene is then covered with soil which is packed down. This treatment it is claimed will kill 90—100% of the borers if the soil temperature is 55°—60° F. (13°—15·5° C.) or higher and the soil is not too wet. —W. G.

[Plant] growth and sap concentration. H. S. Reed. J. Agric. Res., 1921, **21**, 81—98.

OBSERVATIONS on apricot and orange trees show that growth and sap concentration tend to vary in opposite directions. As the season advances there is a gradual increase in sap concentration, this increase being noticeable for some time after active growth has ceased. Of the environmental factors examined, soil moisture was the only one having an obvious effect upon sap concentration, increase in soil moisture causing a diminution in the concentration of the plant sap. Lower concentrations of plant sap in the shoot as a whole appear to be associated with abundant water intake and rapid vegetative growth, higher concentrations with slow growth and fruit-bud formation.—W. G.

Nitrogen-fixing organism; Influence of uranium salts on a ——. E. Kayser. Comptes rend., 1921, **172**, 1133—1134.

THE influence of uranium salts on *Azotobacter agile* depends upon the nature of the salt used, its concentration, and the colour of the containing vessel. Uranium acetate gave an increased fixation of nitrogen and better utilisation of sugar at certain concentrations, but uranium phosphate in every case gave less satisfactory results than the control. —W. G.

Seeds; Effect of salt solutions having definite osmotic concentration values upon absorption by ——. W. Rudolfs. Soil Sci., 1921, **11**, 277—293.

SINGLE salt solutions of calcium nitrate, potassium carbonate, magnesium sulphate, potassium phosphate, sodium chloride, potassium chloride, and sodium nitrate, and one of Shive's three salt solutions R_5C_2 (*cf.* Shive and Martin, J., 1918, 598 A) were used, the osmotic concentration values of the solutions varying from 0·001 to 7·0 atm. The amounts of absorption from these solutions by different varieties of seeds were determined. The results indicate a marked variation in the absorbing power of seeds of different species, leguminous seeds showing the highest rate of absorption of the seeds examined. The rates of absorption are progressively retarded by increase in osmotic concentration values of the solutions, provided there is

no chemical action on the seed coating, there being an approximately linear relation between these two factors. The retardation of absorption rates is apparently due to osmotic resistance offered to the entrance of water into the seed.—W. G.

Hydrocyanic acid in plants. Menaul. *See* VII.

Activated sewage sludge. Fowler. *See* XIXB.

Phosphates; Manufacture of assimilable ——. J. J. Morel. E.P. 160,847, 14.8.20.

MINERAL phosphates, consisting of mixtures of tricalcium phosphate and calcium carbonate, are treated in a rotary furnace at 1000° C. with a continuous current of sulphurous gas, air, and steam, the proportions being such as to give a mixture of mono- and dicalcium phosphate and calcium sulphate. The production of these phosphates is facilitated by adding about 1% of a chloride, *e.g.*, calcium chloride, to the phosphatic material.
—W. J. W.

Organic matter; Treatment of —— *for fertiliser purposes.* A. J. Grinnell. E.P. 136,829, 16.12.19. Conv., 27.4.17.

SEE U.S.P. 1,268,563 of 1918; J., 1918, 522 A.

XVII.—SUGARS; STARCHES; GUMS.

[*Sugar*] *juices which cannot be satisfactorily defecated.* C. Muller. Bull. Assoc. Chim. Sucr., 1921, **20**, 239—247.

DIFFICULTIES in the defecation of juices from canes damaged by heat or frost are due to the presence of abnormal amounts of acetates and other organic salts which cannot be eliminated. As palliative measures the author recommends carbonatation of the juice from the third and fourth crushings, sulphitation of the juice after decantation, and perhaps imbibition with cold water. Cases occur also in which juices from sound canes resist defecation even by large amounts of lime. These are attributed by the author to the presence, in certain canes, of colloidal compounds containing organic and silicious matter not precipitable by lime, which are liberated from the cells ruptured by crushing. Sulphitation is no remedy, but the colloidal matters may be destroyed by superheating the juice at about 116° C. before liming; the organic matter is thereby coagulated and the silica is rendered precipitable by lime. The colour of the juice is also improved, defecation can be effected with about ⅓ of the usual amount of lime, and sulphitation is often unnecessary or it may be postponed to a later stage, *e.g.*, that of syrup.—J. H. L.

Honey; Valuation of artificial ——. V. Stanek and J. Vondrak. Z. Zuckerind. Czecho-Slov., 1921, **45**, 203—205.

FOR the determination of dry substance in artificial honey the authors recommend either the refractometric method, applied to the undiluted material, previously warmed if necessary to dissolve crystals, or the following saccharometric method:—The sp. gr. of a mixture of the sample with an equal weight of water, in degrees Balling, is corrected for temperature if necessary and then multiplied by 2, and from the product 0·7° is subtracted to allow for the effect of contraction on dilution. Both methods give results accurate to about 0·1%.
—J. H. L.

Polysaccharides. VII. Constitution of cellobiose. P. Karrer and F. Widmer. Helv. Chim. Acta, 1921, **4**, 295—297.

HYDROLYSIS of heptamethyl-β-methylcelloside (J., 1921, 342 A) by 5% hydrochloric acid yields tetra- and tri-methylglucoses, and since heptamethyl-β-methylcelloside is obtained by methylation of cellobiose, the latter must, in accordance with the formulæ for tri- and tetra-methylglucoses, be 5-β-d-glucoside-d-glucose. This constitution has been given also by Haworth and Hirst (J., 1921, 234 A), but the heptamethyl-β-methylcelloside used by these authors contained an admixture of heptamethyl-α-methylcelloside.—T. H. P.

Starch; Gelatinisation of —— *in cold water in presence of alkalis or neutral salts.* A. Reychler. Bull. Soc. Chim. Belgique, 1920, **29**, 118—122.

STARCH grains may be rapidly gelatinised at the ordinary temperature by solutions of potassium or sodium hydroxide, but not by ammonia; by using a 0·75% solution of potassium hydroxide the process may be made sufficiently slow for microscopical observation. Many neutral salts also produce gelatinisation. Among the least active are sodium and calcium chlorides, whilst ammonium chloride, stannous chloride, mercuric chloride, lead nitrate, and sodium benzoate are more active, but even in concentrated solutions they act more slowly than 0·75% potassium hydroxide solution. The following substances at the concentrations stated have the same gelatinising power as 0·75% potassium hydroxide solution:—Sodium hydroxide at 0·53%, potassium iodide at 26—28%, ammonium nitrate at 30—35%, silver nitrate at 29%, potassium thiocyanate at 12—15%, and chloral hydrate at 55%. The mechanism of the gelatinisation process is discussed from the botanical standpoint.
—J. H. L.

Amylopectin; The fundamental organic substance of ——. Samec and A. Mayer. Comptes rend., 1921, **172**, 1079—1082.

A NEW classification is suggested for the products of hydrolysis of starch, namely, amyloses (without reducing power), dextrins (with reducing power), dextrinic acids (acid reaction), prefixing these names by amylo-, erythro-, or achroo-, according as the particular member gives a blue, red, or no colour with iodine. The carbohydrate derived from amylopectin would thus be termed an erythroamylose.—W. G.

Inulin; Application of the biochemical method of detection of dextrose to the study of the products of enzymic hydrolysis of ——. E. Bourquelot and M. Bridel. Comptes rend., 1921, **172**, 946—949.

USING the method previously described (J., 1920, 344 A), it is shown that the products of hydrolysis of inulin by the inulase of *Aspergillus niger* contain reducing sugars but no dextrose. Inulin is thus constituted by the condensation of lævulose molecules alone.—W. G.

PATENTS.

Centrifugal apparatus for straining liquids [*sugar juices*]. J. Y. Johnson. From F. W. Fischlein. E.P. 161,822, 26.3.20.

THE apparatus, which is designed particularly for the straining of defecated sugar juices, consists of a casing within which is mounted on ball bearings a vertical shaft carrying one or more conical strainers. The shaft is rotated by means of a turbine at its upper end, to which the juice to be strained is delivered under pressure. After effecting the rotation of the turbine the juice falls from the latter into the top strainer, which preferably has the widest perforations, and passes in turn through the lower and finer ones. In each strainer is a deflector to direct the falling liquid against the conical walls, but a narrow annular opening near the bottom of each strainer permits solid matters retained by the latter to fall into the next strainer

and eventually to escape from the lowest strainer into a special protected outlet at the bottom of the casing. The casing has a separate outlet for the liquid.—J. H. L.

Lactose or milk sugar; Manufacture of ——. J. Tavroges, J. W. Roche, and G. Martin. E.P. 161,887, 22.7.20.

The lactalbumin contained in whey from cheese manufacture is completely precipitated by means of a colloidal substance added to or produced in the whey. For example, the whey, heated to 70°—80° C., is treated with about 0·25% of sodium thiosulphate, which by reacting with the free acid of the whey produces a precipitate of colloidal sulphur; the latter, being negatively charged, precipitates the positively charged albumin. After removal of the precipitate the whey is concentrated for the recovery of lactose.—J. H. L.

Caramel; Substitute for ——. H. Thoms. G.P. 333,115, 1.4.20.

Vegetables which contain carbohydrates in any form, such as cellulose, lignocellulose, galactans, etc., are subjected to acid hydrolysis, *e.g.*, by heating with dilute hydrochloric acid under atmospheric or higher pressures, and the product is evaporated to dryness and heated to 200° C. to caramelise the sugars. Remaining traces of acid and other odourous substances may be removed by a current of air. The residual brown mass is extracted with water and the filtered extract is concentrated.—J. H. L.

Starch; Production of —— *from potatoes.* H. Wertheim; and Nyitraer Stärkeindustrie-A.-G. G.P. 331,378, 1.3.17. Conv., 3.2.17.

The pulped potatoes are freed from juice as far as possible by known methods and then treated with the minimum amount of water necessary to remove the remaining extractive matters, and finally the starch is washed out with water as usual. The process renders possible the complete recovery of all valuable constituents of the potatoes, and avoids the difficulties associated with the treatment of waste waters obtained by the usual methods.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation; Researches on ——. *VII. Influence of additions (toluene, chloroform, thymol, and neutral salts) upon the fermentative decomposition of dipeptides by yeast extract.* E. Abderhalden and A. Fodor. Fermentforsch., 1920—1, 4, 191—208.

Experiments were carried out on the decomposition of glycyl-*l*-leucine by yeast extract, the course of the reaction being followed at intervals of 10 mins. by the formaldehyde titration method. Additions of toluene, chloroform, and thymol had no effect upon the decomposition, which is explained by the fact that these substances have no influence upon the colloidal state of the yeast enzymes. The addition of small amounts of sodium chloride caused a slight retardation in the reaction, which was increased by increasing the amount of salt added; whether the yeast extract were fresh or old made little material difference. With additions of potassium chloride, bromide, nitrate, and sulphate there was a slight acceleration of the reaction during the first interval of time, then a slight retardation, and then a rapid inhibition. This result was given by a concentration of two-thirds an equivalent of each salt per l.; with higher concentrations the inhibition began earlier. Potassium iodide and thiocyanate produced at once a marked diminution in the reaction. It is concluded that the influence of the salt added is of a complex nature and depends upon the change produced in the electric charge of the solution and upon the change in the colloidal state produced thereby. The addition of the salts has the effect of displacing the hydrogen ion concentration of the solution towards the acid side of the scale.—J. H. J.

Fermentation. VIII. Production of ferment sols from yeast phosphoprotein. Activity of the sols as a function of the colloidal state. A. Fodor. Fermentforsch., 1920—1, 4, 209—229.

Yeast maceration extract prepared in the usual manner was treated with dilute hydrochloric acid when the phosphoproteins were precipitated; these were then washed with water and triturated with water to form sols, which in the absence of traces of acid were stable and fermented solutions of polypeptides. The sols obtained were examined ultramicroscopically and various degrees of dispersion were noticed. It was found that the fermentative activity varied directly with the degree of dispersion of the sol. The addition of alkalis and of alkali phosphates increased the degree of dispersion and the fermentative activity of the sols. The addition of potassium chloride in small amounts increased the fermentative activity, but in large amounts caused flocculation. Yeast phosphoproteins which have become more or less inactive can be regenerated, preferably by the addition of alkali and potassium chloride, with a corresponding increase in degree of dispersion.—J. H. J.

Diastase; The co-enzyme (complement) of ——. W. Biedermann. Fermentforsch., 1920–1, 4, 258—300.

Animal and plant diastases consist of a thermolabile and by itself inactive component (zymogen) and a thermostable co-enzyme, such as an inorganic salt. Many experiments were carried out to determine the effect of salts on diastatic fermentation and also on the influence of the reaction of the solution. It was found difficult to obtain by dialysis a completely inactive diastase solution, as traces of salts were sufficient to activate the enzyme. The salts used as activators were the neutral salts of the alkali and alkaline-earth metals with inorganic and organic acids, phosphates, bicarbonates, and thiocyanates. The anion proved to be the active component. The most active salt was sodium chloride, closely followed by potassium thiocyanate; in the second rank were potassium chloride and bromide, sodium bromide, and ammonium chloride; in the third rank were the chlorides of calcium, magnesium, strontium, and barium. After these came nitrates, iodides, and sulphates. Of the cations sodium had the most influence, followed by potassium. All the salts form with diastase complex compounds of indefinite composition which are easily dissociated. The activity of these neutral salt-diastases is greater in strictly neutral solutions; the slightest addition of acid and alkali is enough to check fermentation at once, and with long contact the enzyme is destroyed. Alkaline and acid salts behave differently from neutral salts. Acid sodium phosphate and acid sodium citrate in solutions up to 0·3% strength activate salt-free diastase in spite of the acid reaction of the mixture; above this strength the reaction is checked. Disodium phosphate and sodium bicarbonate activate fermentation in concentrations in which the more acid salts would inhibit. There is a relative retardation produced by disodium phosphate which

can be removed at once by a trace of sodium chloride, the reaction remaining neutral. The diastatic power of this mixture exceeds that of all others. The high activating power of phosphate ions is shown by the fact that the activating power of a sodium chloride solution is not only unimpaired but is considerably increased by a slight addition of a diphosphate. Similarly sodium carbonate does not cause any checking of an active sodium chloride-diastase. Saliva yields a diastase solution which depends for its activity upon the composition of the co-enzyme, that is, the combination of inorganic salts, the most important of which are sodium chloride, potassium thiocyanate and phosphate, to which must be added bicarbonate and carbon dioxide, which play an important part in the diastatic fermentation of pancreatic juice.
—J. H. J.

Carboligase: an enzyme linking carbon chains. C. Neuberg and J. Hirsch. Biochem. Zeits., 1921, **115**, 282—310.

By the fermentation of sucrose or dextrose by top yeast, bottom yeast, or maceration juice in the presence of benzaldehyde a hydroxy-ketone of the constitution, $C_6H_5.CO.CH(OH).CH_3$ or $C_6H_5.CH(OH).CO.CH_3$, is formed. Its production is attributed to the presence in yeast of a new enzyme, to which the name carboligase is given, which produces a condensation of the benzoïn type between one molecule of benzaldehyde and one either of acetaldehyde or of pyruvic acid, its precursor in alcoholic fermentation. The same compound is formed by the action of yeast upon a mixture of benzaldehyde and pyruvic acid, but the direct condensation of the two aldehydes cannot be effected. (*Cf.* J.C.S., June.)—E. S.

Amygdalinase and amygdalase; Curious modification of —— due to ageing. G. Bertrand and A. Compton. Bull. Soc. Chim., 1921, **29**, 229—237.

Under the influence of time amygdalinase and amygdalase, as extracted from almonds, lose their activity very slowly, to the extent of about one-third in ten years, but they show a marked variation in the optimum hydrogen-ion concentration for the medium in which they act. Thus a sample of emulsin (amygdalinase+amygdalase) prepared in 1910 showed maximum activity in a medium slightly alkaline to phenolphthalein, but when examined in 1914 it showed maximum activity in a medium slightly acid to this indicator.—W. G.

Enzymes of B. coli communis. V.—(a) Anaërobic growth followed by anaërobic and aërobic fermentation. (b) The effects of aeration during the fermentation. E. C. Grey and E. G. Young. Proc. Roy. Soc., 1921, **92 B**, 135—150.

Anaërobic fermentation of dextrose by an emulsion of *B. coli communis* proceeds differently according as the organisms have been grown previously with or without oxygen. When the immediate past history has been anaërobic the fermentation under anaërobic conditions yields little or no lactic acid and a greatly diminished quantity of succinic acid. In place of these acetic acid appears in large proportion. Admission of oxygen during the fermentation leads to lactic acid production, there being an increase in lactic, acetic, and succinic acids and a diminution in hydrogen, carbon dioxide, and formic acid, the alcohol remaining pactically constant. Under anaërobic conditions greater variations occur in the proportion of alcohol to acetic acid than under aërobic conditions, one of the effects of the introduction of oxygen during the fermentation being apparently to inhibit the mechanism of auto-reduction which is responsible for the variations in alcohol. Another effect of the introduction of oxygen is probably to diminish the part played by water in the reactions.
—W. G.

Bacteria; Influence of fats on the growth of ——. H. Much and H. Schmidt. Z. Immunitätsforsch. Exp. Ther., 1920, **31**, 169—200. Chem. Zentr., 1921, **92**, I., 645.

The addition of fats to nutrient media does not accelerate the growth of bacteria; with many species the growth is hindered, and chaulmoogra oil has a retarding effect on all bacterial growth. Staphylococci decompose the fats, and in a fatty medium the organisms themselves appear to be somewhat larger than usual and to a certain extent swollen, but their other properties remain unaltered, except when chaulmoogra oil is present.
—W. P. S.

Fruit [for wine making]; Influence of degree of ripeness of —— on the acceleration of fermentation by various nitrogenous compounds. Cellar experiments to secure pure fermentation and stability of fruit wines. Lactic acid malady appearing in fruit wines after complete fermentation of the sugar. Importance of blending for the stability of mild fruit wines. H. Müller-Thurgau and A. Osterwalder. Landw. Jahrb. der Schweiz, 1920. Chem. Zentr., 1921, **92**, II., 748—750.

Expressed juices from unripe, ripe, and over-ripe pears of four kinds were fermented with and without addition of ammonium chloride or carbonate, and with and without the use of pure culture yeast. The effect of ammonium salts confirmed previous conclusions (J., 1919, 333 A); they accelerated the fermentation of juice from unripe pears less than that of juice from ripe pears, and it is concluded that the former already contain more assimilable nitrogen than the latter. Spontaneous fermentation was in all cases sluggish, but with addition of pure yeast the juices from unripe fruit fermented at least as rapidly as those from ripe fruit, the higher tannin-content of the former having no perceptible retarding influence. Most fruit wines, especially those of low acidity and tannin-content, require more careful treatment in the cellar than grape wines. A common malady is one in which lactic and acetic acids are formed, and unlike ordinary acetous fermentation this cannot be checked by exclusion of air. The best preventive measures are rapid fermentation, *i.e.*, use of pure yeast and ammonium salts, and avoidance of high temperatures. Treatment with sulphur dioxide or metabisulphite is desirable to prevent the development of the malady after fermentation. The malady is distinct from that in which mannitol and lactic and acetic acids are formed from sugar by *Bact. mannitopacum*; in the former the acids appear to be produced from glycerol and other unknown constituents, for it may develop after all the sugar has been fermented. In the case of juices of low acidity and tannin-content the malady may be warded off during fermentation by mixing such juices, before fermentation, with apple or pear juices rich in acid and tannin (pear juices rich in tannin alone are not so suitable). The mixed juice is fermented as rapidly as possible and afterwards sulphited.—J. H. L.

Maize silage. Fred and others. *See* XIXA.

Patents.

Acetone and higher alcohols, particularly butyl alcohol; Method and apparatus for the production by fermentation of ——. A. Fernbach. E.P. 109,969, 30.8.17. Conv., 31.8.16.

The method described in E.P. 15,203, 15,204, and 16,925 of 1911, and 21,073 of 1912 (J., 1913, 987),

may be carried out in apparatus of the kind described in E.P. 15,561 of 1898 (J., 1898, 1066); this apparatus comprises fermentation vats each provided with a feeding orifice, an agitator, a system of pipes for the introduction of air or inert gas, communicating pipes, and a filter. A small "leavening vat" is used in conjunction with the fermentation vats, and means are provided by which the reduced pressure resulting from the cooling of the sweet wort after sterilisation is utilised for introducing the culture.—W. P. S.

Wood and other cellulose-containing substances; Manufacture of sugar and furfural from ——. A. Classen. E.P. 142,480, 27.4.20. Conv., 18.3.19.

The material is heated under a steam pressure of about 7—8 atm. with sufficient dilute sulphuric or hydrochloric acid to effect conversion, but one or more additional acids, or salts capable of yielding acids, are employed at the same time as catalysts. The action of the additional acids improves the yield and fermentable quality of the sugar produced, and the yield of furfural can be increased by a suitable choice of additional acids, *e.g.*, sulphuric and sulphurous acids when hydrochloric acid is used for conversion, or hydrochloric and sulphurous acids when sulphuric acid is used for conversion. Besides acid catalysts metals or metallic oxides, especially those of the iron group, may be employed.—J. H. L.

Glucose [for fermentation] from wood; Process and apparatus for obtaining ——. H. Terrisse and M. Levy. E.P. 143,212, 6.5.20. Conv., 13.5.19.

Dry sawdust is treated in a mixing cylinder with about twice its weight of 33% hydrochloric acid and is then conveyed through other mixing cylinders into each of which gaseous hydrochloric acid is introduced so as to increase the acid concentration to about 41%. During these operations the temperature is maintained at 0°—25° C. The impregnated material is digested in a rotating vessel at a slightly higher temperature for 10 hrs., and the excess of hydrochloric acid is removed by raising the temperature to about 30° C. and reducing the pressure to 40 mm., the gaseous acid being absorbed and collected. The residual mass is extracted with water, the extract filtered and distilled under reduced pressure to remove hydrochloric acid completely.—W. P. S.

Cellulose-containing materials; Saccharification of ——. A. Wohl. E.P. 146,860, 5.7.20. Conv., 7.4.17.

The material is intimately mixed with strong mineral acid, *e.g.*, 70—75% sulphuric or 39—40% hydrochloric acid, and subjected to powerful agitation and compression. The amount of acid required is much less than when the material is not kneaded and pressed, *e.g.*, 1·5 pt. of 75% sulphuric acid is sufficient for 1 pt. of wood waste.—J. H. L.

Cellulose; Fermentation of ——. The Power-Gas Corporation, Ltd., and H. Langwell. E.P. 161,294, 8.1 and 18.3.20. Addn. to 134,265 (J., 1920, 38 a).

In the process described (*loc. cit.*) acetic acid is the chief product when the aeration is limited; if the rate of aeration is increased, alcohols, particularly ethyl alcohol, are the principal products of the fermentation.—W. P. S.

Yeast; Manufacture of pressed —— from distillers' grains, oil-cake and the like. J. Effront. E.P. 160,496, 21.11.19.

Nitrogenous material such as oil-cake, distillers' grains, etc., is digested with concentrated hydrochloric or other mineral acid for 48 hrs. at 106°—108° C. The extract obtained, which is rich in amino-acids, is employed as yeast food, whereby the amount of sugar consumed by the yeast without production of alcohol is much reduced.—J. H. L.

Fermented liquors; [Use of sour whey solids in the] manufacture of ——. C. S. Townsend. E.P. 160,562, 23.12.19.

The solids obtained by the desiccation of sour whey from the manufacture of cheese are employed as a constituent of fermented beverages, *e.g.*, "stone ginger beer." They assist fermentation and give a distinctive flavour to the beverage. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 20,183 of 1912; J., 1913, 987.)—J. H. L.

Fermentation process. A. Römer, and Deutsch-Koloniale Gerb- u. Farbstoff-Ges. m.b.H. E.P. 161,870, 17.6.20.

In a continuous process for the fermentation of saccharine liquids, *e.g.*, molasses worts or sulphite-cellulose liquors, the liquid is passed through a series of "ferment filters," *i.e.*, cylindrical vessels containing yeast fixed in kieselguhr, sawdust, or the like. The liquid is passed upwards through each vessel, at a suitable temperature and at such a rate that after traversing the whole series, *e.g.*, 6 vessels, it is completely fermented. The order of the vessels may be changed at will so that the yeast in any one does not remain too long in contact with liquid poor or rich in sugar. Any vessel may be cut out of the series, re-charged with fresh yeast, and brought into operation again without arresting the working of the others. For the fermentation of liquids poor in sugar one filter may suffice. The process may be adapted to other types of fermentation, *e.g.*, to the production of butyl alcohol, glycerol, lactic, butyric, or citric acid, acetone, etc. —J. H. L.

Mashing process. H. E. Deckebach. U.S.P. 1,374,191, 12.4.21. Appl., 20.9.19.

Ground malt is mashed in a mash tun and raw grits are simultaneously heated with water in a converter, and the two vessels are so connected that the materials can be circulated from the tun into the converter and from the converter into the tun, until the starch is saccharified.—J. H. L.

Fermentation of beer and the like [by the Burton union system]; Apparatus for ——. J. F. Warwick. E.P. 161,496, 16.8.20.

Caramel substitute. G.P. 333,115. *See* XVII.

Foods. E.P. 161,885. *See* XIXa.

XIXa.—FOODS.

Milk; Relation between lactic acid production and bacterial growth in the souring of ——. J. C. Baker, J. D. Brew, and H. J. Conn. New York Agric. Expt. Stat. Bull. No. 74, 1919. 24 pages.

The rate of acid production per individual cell per hr. with different cultures of bacteria, varied considerably, being much lower in the case of an organism which multiplied arithmetically than with one which multiplied normally (geometrically); for a vigorous culture the rate was between 5×10^{-10} and 10×10^{-10} mg. of lactic acid per hr. The ratio of total acid produced to the number of organisms present proved to be fairly constant, and was directly proportional to the amount of acid produced per generation by each individual cell; the ratio increased as the curdling point was approached. There was a tendency for the acid present to increase geometrically until coagulation ensued and, to a certain extent, this was true even with the organisms which were multiplying arith-

metically. At the curdling point, the multiplication of the bacteria appeared to cease and there was a noticeable decrease in the rate of acid production. The bacteria were, in all cases, counted individually under the microscope.—W. P. S.

Milk powders; Antiscorbutic potency of ——. E. B. Hart, H. Steenbock, and N. R. Ellis. J. Biol. Chem., 1921, **46**, 309—318.

Apart from the original content of vitamin, as influenced by fodder, the powders vary with the process of manufacture used; the spray processes are more destructive than the Just (heated rolls) process. With the possible exception of powders made by the Just process from summer milk (or even from winter milk obtained on a vitamin-rich diet of roots and tubers) these preparations must be supplemented in infant feeding by some potent source of antiscorbutic vitamin.—G. B.

Vitamin; Stability of the antiscorbutic ——, *and its behaviour to various treatments.* N. R. Ellis, H. Steenbock, and E. B. Hart. J. Biol. Chem., 1921, **46**, 367—380.

The antiscorbutic vitamin in cabbage is destroyed by desiccation at 65° C., even in an atmosphere of carbon dioxide, and also by the fermentation involved in the making of sauerkraut, and of silage from maize. It is not removed from orange juice by ether or by aeration, but is destroyed by oxidising agents. Blood charcoal and the Chamberland filter remove a measurable amount from orange juice.—G. B.

Fats; Special nutrition values of different ——. *Accessory food factors. I.* H. Aron and R. R. Gralka. Biochem. Zeits., 1921, **115**, 188—203.

Feeding experiments on rats are described which confirm the presence of vitamin A in cod-liver-oil, butter, and egg-yolk, and its absence in margarine. —E. S.

Alimentary ration and vitamins. A. Desgrez and H. Bierry. Comptes rend., 1921, **172**, 1068—1071.

On a ration, deprived of fats, containing only protein and carbohydrates, but rich in vitamins, the growth of young rats and the equilibrium of adult animals can be assured, but in the complete absence of vitamins, nitrogen equilibrium can only be maintained if the constituents of the ration are all present and in certain proportions.—W. G.

Egg preparations; Drying and preserving of ——. Briant and Harman. Nat. Assoc. Review, 1921, **38**, 247—251.

The baking value of eggs lies in their power of retaining gas produced by baking powders etc. in the dough, and the value is dependent on the amount of coagulable albumin present. In the case of dried eggs a portion of the albumin may be coagulated during the drying process, especially if the temperature exceeds 65° F. (19° C.), and the loss due to coagulation is increased by the presence of small quantities of boric acid.—W. P. S.

Lactic acid bacteria; Relation of —— *to corn [maize] silage.* E. B. Fred, W. H. Peterson, and J. A. Anderson. J. Biol. Chem., 1921, **46**, 319—327.

Lactobacillus pentoaceticus plays an important part in maize silage and increases the amount of alcohol and volatile acid, while the lactic acid is decreased. *Bacillus lactis acidi* persists only during the first days of fermentation.—G. B.

Pentosans; Destruction of —— *in the formation of silage.* W. H. Peterson, E. B. Fred, and J. H. Verhulst. J. Biol. Chem., 1921, **46**, 329—338.

Corn (maize) fodder contains 21·8% of pentosans and 0·34% of methylpentosans. After fermentation for 50 days the content of pentosans ranges from 17·6 to 20·9% according to the moisture present. Taking account of the loss of dry matter, at least 15—20% of the pentosans is destroyed during fermentation. Pentoses or other furfural-yielding substances soluble in water occur, probably as the result of bacterial action. A mixture of 2% of acetic and 5% of lactic acid did not appreciably hydrolyse pentosans in 20 days at 28° C. Immature maize contains 0·6% of free pentoses.—G. B.

Silage crops; Application of the Van Slyke method to hydrolysed protein extracts of ——. R. E. Neidig and R. S. Snyder. J. Amer. Chem. Soc., 1921, **43**, 951—959.

The proteins of forage crops, either before or after conversion into silage, cannot be successfully analysed by the Van Slyke method applied directly to the hydrolysed extract of the original material, because of the formation of considerable quantities of humin from the cellulose. The method of Eckstein and Grindley (J., 1919, 301 A) gives results which permit of a fair interpretation of the protein molecule when applied to concentrates which contain but little cellulose.—W. G.

Patents.

Grape honeys and fruit syrups; Process and apparatus for the manufacture of ——. E. Barbet et Fils et Cie. E.P. 153,548, 21.1.20. Conv., 31.10.19. Addn. to 135,175 (J., 1921, 364 A).

The apparatus previously described (*loc. cit.*) has the disadvantage that the vapours given off from the first evaporation are sometimes charged with sulphurous acid, which slowly attacks the copper and may thereby contaminate the juice. This is obviated by subjecting the sulphited juice to a preliminary desulphitation in a tower used in conjunction with each of the evaporating groups of the earlier apparatus and made of ceramic ware or volvic lava. The desulphitation is effected by means of juice vapour introduced into the bottom of the tower through a regulating valve. The desulphited liquor passes from the bottom of the tower to the evaporator.—G. F. M.

Eggs; Method of preserving ——. G. Dreyer and G. F. Hanson. E.P. 161,110, 21.7.20.

Eggs are immersed in, or washed with, formaldehyde solution or with water containing chlorine, and are then stored in a receptacle through which a current of moist sterilised air at 5° C. is passed. The eggs are turned once every 24 hrs. during storage.—W. P. S.

Alimentary products containing water-soluble vitamines; Manufacture of ——. "Forget-me-not-Flours," Ltd., and R. Hutchinson. E.P. 161,238, 23.12.19.

Wheat bran, or the husk of other edible seeds, is dried at 100° F. (38° C.) under reduced pressure and ground; the powder may be used as such or an aqueous infusion may be prepared from it. The infusion may be mixed with gelatin etc., and formed into tablets, or it may be evaporated under reduced pressure to produce a dry powder. Filtration of the infusion is optional.—W. P. S.

Food preparation [from pine seeds]; Production of a ——. C. Farmachidis. E.P. 161,291, 8.1.20.

Shelled pine seeds are washed, dried, ground, and

mixed with flour and gluten; other substances, such as baking powder, sugar, flavouring matter, etc., may be added. The mixture is formed into biscuits, which are baked at 130° C.—W. P. S.

Vegetable gelatin; Process of making [edible] —— and the product thereof. M. M. Malcolm and C. S. Townsend. E.P. 161,612, 10.11.19.

VEGETABLE gelatin is prepared from seaweed, especially from *Chondrus crispus* or carragheen, by soaking the material in water for some hours, washing to remove impurities and salts, bleaching the softened substance with "floridin," "norit," or albumin, disintegrating by boiling with 5 pts. of water containing acids or alkalis, preferably 0·5% acetic acid, with gentle agitation, and finally expressing the liquid from the undissolved residue. A preservative such as 0·5% of bisulphite, or 1·0% of sodium benzoate, is added to the liquor, and the gelatin may be dried by running the filtered material on to heated rollers, to produce sheets; by atomising the liquor after a preliminary concentration, into a chamber through which a current of hot air is passed, whereby a gelatin powder is produced, or by drying the concentrated liquor in trays in an oven to produce the material in block form.—G. F. M.

Foods: Process for the preservation of by-products of brewing, distillation and other processes for use as animal ——. A. Stouffs. E.P. 161,885, 19.7.20.

BY-PRODUCTS suitable for feeding-stuffs, *e.g.*, brewers' grains, exhausted beet slices, etc., may be preserved from fermentation for about 10 months by moistening them with dilute hydrochloric acid at the rate of 1 kg. of 33% fuming acid diluted with 200 l. of water per 1000 kg. of material. The products may be compressed into cakes.—J. H. L.

Meat; Process of producing powdered ——. J. C. MacLachlan, Assr. to Standard Food Products Co. U.S.P. 1,372,527, 22.3.21. Appl., 26.5.19.

FINELY-CUT or ground meat is projected by centrifugal force into a hot drying medium, in which it is intercepted, beaten, and desiccated.—J. H. L.

Cheese; Process of sterilising ——. E. E. Eldredge. U.S.P. 1,374,141, 5.4.21. Appl., 24.9.19.

CHEESE is mixed with 2% of its weight of sodium phosphate, and then heated at a suitable temperature.—W. P. S.

Sugar; Composition of —— and method of preparing the same. N. C. Fowler, jun.; F. A. Fowler, admintrix. U.S.P. 1,374,160, 5.4.21. Appl., 8.8.16. Renewed 16.4.18.

DRIED fruit is ground with the addition of water and sugar, the mixture dried, and then re-ground. —W. P. S.

Milk; Production of dehydrated ——. S. M. Dick, Assr. to International Dry Milk Co. U.S.P. 1,374,555, 12.4.21. Appl., 31.1.20.

MILK is atomised without pressure in a suitable dehydrating cell, and is exposed to the action of compound currents of heated air. It is thereby dried without breaking or injuring the globules of butter fat, which become coated with casein, albumin, and other colloidal constituents of the milk. The product is readily soluble with the production of a liquid substantially the same as normal milk, on which the cream will rise in the usual way. —G. F. M.

Food product; Manufacture of a —— [from sugar residues or the like]. H. Stoltzenberg. G.P. 329,321, 24.4.19.

RESIDUES from the desaccharification process, *e.g.*, osmose molasses, wash liquors, etc., are treated hot with an organic solvent, such as alcohol or a ketone or ester, and after the mixture has cooled and stood for some time, the upper layer, *i.e.*, the organic solvent, which contains the unwholesome constituents in solution, is separated. After the lower layer has stood for a further period, the amino-acid salts which settle out are removed, converted to the free acids, and returned to the solution, which has in the meantime been freed from the last traces of organic solvent by heat. The product can be employed as a food product or as fodder, or can be fermented to yield an alcoholic beverage or for the production of pressed yeast, or it can be utilised in the manufacture of sweetstuffs and the like. —L. A. C.

Rennet, rennet extracts and the like; Process for the preparation of ——. Gebr. Schubert. G.P. 333,458, 5.6.18.

THE material is fractionally extracted with alcoholic calcium chloride solution and the united extracts evaporated. The use of calcium chloride allows of the concentration of weak extracts without precipitation of the salts or the enzyme.—A. de W.

Food from fish-flesh; Preparation of ——. M. Jewnin. G.P. 333,554, 8.4.19.

THE comminuted flesh is extracted with aqueous alcohol of a strength not exceeding 70%, and is then mixed with amino-acids resulting from the acid hydrolysis of proteins and with flour. The product is free from the characteristic, disagreeable fishy flavour.—A. de W.

Fodder; Process for the conversion of the stomach-contents of animals into a dry ——. G. Beckstroem. G.P. 334,170, 17.6.19. Addn. to 300,063 (J., 1919, 960 A).

FISH or fish waste may be employed together with stomach-contents and cellulosic matter. The bacteria which develop attack fish bones, scales, and fins.—J. H. L.

Desiccating buttermilk, sour milk, and the like; Apparatus for ——. Collis Products Co., Assees. of N. P. Collis. E.P. 138,092, 20.1.20. Conv., 13.12.15.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Determination of the hydrogen ion concentration of ——. I. M. Kolthoff. Z. Unters. Nahr. Genussm., 1921, **41**, 112—122.

A COLORIMETRIC method for the determination of the hydrogen ion concentration of water consists

in treating the water with Neutral Red solution and comparing the coloration with that of standardised acid and alkaline solutions of the same indicator contained in graduated wedge-shaped tubes. The carbon dioxide content of a water may be calculated from the hydrogen ion concentration and the bicarbonate content by the formula $[H_2CO_3]=[H^{\cdot}]\ [HCO'_3]\ /3{\cdot}04\times10^{-7}$.—W. P. S.

Water; Influence of minute quantities of metallic salts in —— on its bacteriological content. E. L. Atkinson and R. C. Frederick. J. Roy. Nav. Med. Service, April, 1921. [Reprint.] Pp. 5.

NATURAL waters of different types were treated with lead acetate, copper sulphate, ferric chloride, or zinc sulphate, equivalent to 0·5 and 0·25 pt. of metal per 100,000, and after inoculation with *B. typhosus* each sample was sub-cultured into ordinary nutrient broth tubes on four successive days. The results show that even 0·25 pt. of copper per 100,000 in the water markedly inhibited development in the cultures; zinc had a slight effect at 0·5 pt. per 100,000 but practically none at 0·25 pt., whilst lead and iron at 0·5 pt. per 100,000 were without any appreciable action. In further experiments an upland surface water and a mixture of shallow well and upland surface waters were treated with salts as above, and after standing for 48 hrs. were subjected to routine bacteriological analysis. Here again the results were seriously affected even by 0·1 pt. of copper per 100,000 of water, and lead and zinc at 0·5 pt. per 100,000 appeared to influence the results in some cases. The authors conclude that a chemical analysis of water is necessary for the interpretation of the results of bacteriological tests.—J. H. L.

Nitrogen; Conservation of —— with special reference to activated [sewage] sludge. G. J. Fowler. J. Indian Inst. Sci., 1920, 3, 227—279.

AN extensive review is given of the existing data as to the nature and amount of the nitrogen in fæces and sewage and of the attempts which have been made to recover some of its value for agricultural purposes. In the activated sludge process of sewage purification there appears to be an increase of nitrogen in the end products over the quantity in the crude sewage treated. Laboratory experiments in which activated sludge and sewage were agitated together by means of an air diffuser, the clarified liquid being withdrawn daily for 5 days and fresh sewage added, showed that the sum of the total nitrogen in the original sludge and in the sewage added daily amounted to 1·793 g., and that in the effluent withdrawn daily and in the final sludge amounted to 1·865 g., an increase of about 4%. In experiments on the incubation of activated sludge with culture solutions favourable for the growth of nitrogen-fixing bacteria, there was found to be a gain of nitrogen of 25% in 4 weeks. For the purpose of studying the effect of activated sludge and the products of its decomposition on plant growth, a seedling was grown in sand partially immersed in activated sludge and water. Aeration was continued for 3 weeks when the liquid contained, per 100,000 pts., 0·03 pt. of ammonia and 0·2 pt. of nitrite, whereas a control experiment with sludge and air showed only 0·5 pt. of ammonia and 0·05 pt. of nitrite, and another with plant and sludge only 2·8 pts. of ammonia and no nitrite. The experimental plant grew well, whereas the control plant gradually died. It is suggested that the stimulating effect of activated sludge on plant growth may be due to the presence of auximones.
—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Caffeine in yerba maté, coffee, tea, kola nut, and guaraná; Determination of ——. T. Ugarte. Anal. Soc. Quím. Argentina, 1920, 8, 413—415.

HALF a gram of the finely powdered substance is introduced into a 500 c.c. flask, and carbonised by heating with a small flame. Dense white vapours are evolved and the heating is so regulated that they do not reach to the upper part of the neck of the flask. After cooling, the contents of the flask are washed out with successive 5 c.c. portions of water and filtered. The united filtrate is evaporated to dryness on a water bath and the residue redissolved in 2 c.c. of water. A few drops of $N/1$ ammonia solution and 5 c.c. of chloroform are added. After agitating, the two liquids are filtered through filter paper impregnated with chloroform and washed with two 5 c.c. portions of chloroform. The filtrate and washings are evaporated to dryness. Caffeine is extracted from the residue with successive small quantities of water and weighed after drying at 100°—105° C.
—G. W. R.

Cacao; Determination of alkaloids in ——. A. Ceriotti. Anal. Soc. Quim. Argentina, 1920, **8**, 400—403.

Ten grams of the fat-free material is boiled for at least 1 hr. with 150 c.c. of 5% sulphuric acid under a reflux condenser. Colouring matters, tannins, and resins are then precipitated by addition of 200 c.c. of 3% mercuric acetate, and the boiling is continued for another 10 mins. The filtrate after neutralisation with magnesia is evaporated to 50 c.c. on a water bath. After addition of 10 g. of sand and excess of calcined magnesia the liquid is evaporated to dryness. The alkaloids are extracted from the powdered residue in a Soxhlet apparatus by a mixture of benzene and chloroform (1:1) and, after removal of the solvents, weighed in a tared dish. The weight of theobromine is obtained by difference after three successive extractions with carbon tetrachloride to remove the caffeine.

—G. W. R.

Alkaloids of valerian. A. Goris and C. Vischniac. Comptes rend., 1921, **172**, 1059—1061.

Waliszewski's statement (Union Pharm., 1893, **34**, 251) as to the existence of the two alkaloids chatinine and valerine in valerian root is confirmed. From 1 kg. of fresh root 0·1 g. of mixed alkaloids was obtained, the chatinine predominating. Chatinine is soluble in ether, whereas valerine is insoluble in ether but soluble in chloroform.—W. G.

Alkaloids; Behaviour of phospho- and silico-tungstic acids towards ——. A. Heiduschka and L. Wolf. Schweiz. Apoth.-Zeit., 1920, **58**, 213—218, 229—233. Chem. Zentr., 1921, **92**, II., 840—841.

The precipitates obtained by the addition of silicotungstic acid to alkaloidal solutions are colloidal with the exception of the quinine and caffeine precipitates. The addition of electrolytes causes coagulation. An equilibrium exists between the neutral and acid salts, depending on the concentration of the acid during precipitation and during washing. By using $N/100$ solutions of silicotungstic acid in presence of 1% hydrochloric acid, sparteine, quinine, cinchonine, and nicotine are precipitated as di-acid bases corresponding to the formula $SiO_2,12WO_3,2H_2O,2Alkaloid,xH_2O$, whilst the composition of the precipitates obtained with morphine, codeine, thebaine, and cocaine is represented by $SiO_2,12WO_3,2H_2O,4Alkaloid,xH_2O$. In other cases the precipitate has no simple composition, and a quantitative determination is accordingly impossible in consequence of the alteration in composition by washing. Alkaloids forming silicotungstates which are only slightly altered by 0·1% sodium chloride solution can, in the absence of albumin, be determined by adding an excess of silicotungstic acid standardised with sodium hydroxide and methyl red, followed by 1% sodium chloride, filtering and washing the precipitate with 0·1% sodium chloride solution, and titrating back the excess acid in the filtrate and washings. Phosphotungstic acid behaves in a similar manner towards alkaloids. In presence of less than 1% of hydrochloric acid, sparteine, quinine, cinchonine, and nicotine give precipitates corresponding to the formula $2[P(W_2O_7)_6]H_7,3Alkaloid,xH_2O$, in other cases the composition is dependent on external conditions. The solubility of the alkaloidal silico- and phosphotungstates is affected to varying extents by the addition of hydrochloric acid or sodium chloride, but minute quantities of alkaloids can be determined with some degree of exactitude by comparing the opalescence produced by silicotungstic acid with that produced in a solution of known strength.

—G. F. M.

Hydrocyanic acid; Micro-crystalline reaction for the identification of —— *in cyanogenetic glucosides.* G. Denigès. Comptes rend. Soc. Biol., 1921, **84**, 309—310. Chem. Zentr., 1921, **92**, II., 623—624.

The substance to be tested is ground with water and, after some time, a portion is placed in a short, narrow test-tube; the mouth of the latter is covered with a microscope slide carrying on its under side a drop of alloxan reagent which has been rendered ammoniacal previously. The alloxan reagent is prepared by dissolving 1 g. of uric acid in a mixture of 1 c.c. of nitric acid (sp. gr. 1·40) and 1 c.c. of water and diluting to 50 c.c. If hydrocyanic acid is present, star-shaped crystals of oxaluramide are formed in the drop of reagent, usually within a few minutes. The test is more sensitive when pyridine is used in place of ammonia; in this case the crystals are in the form of bundles. It frequently happens that the reagent mixture shows a red coloration due to the simultaneous formation of murexide.—W. P. S.

Quinic acid; Presence of —— *in the leaves of some conifers.* G. Tanret. Bull. Soc. Chim., 1921, **29**, 223—229.

The author has isolated quinic acid from the leaves of cedar trees growing in the neighbourhood of Paris, finding 5 g. of the crystallised acid per kg. of leaves (dried at 100° C.) picked in July, but only 2 g. per kg. in leaves picked in December. Similar results were obtained with larch leaves, but the acid could not be isolated from leaves of yew, juniper, or fir trees. The addition of ammonium molybdate causes marked modifications in the rotatory power of quinic acid. With increasing quantities of ammonium molybdate the value of $[\alpha]_D$ (−43·2°) first increases to a maximum (−63°), then falls to a minimum (−54·8°), and finally increases again to a maximum limit value (−71·7°).—W. G.

Capsella bursa pastoris; Active constituents of ——. H. W. van Urk. Pharm. Weekblad, 1921, **58**, 553—556. (*Cf.* Boruttau and Cappenberg, J., 1921, 276 A.)

Alkaloids and allyl mustard oil are absent, and the presence of glucosides is very doubtful. (*Cf.* J.C.S., June.)—S. I. L.

Bromural. E. Yoshitomi and K. Watanabe. Yakugakuzasshi (J. Pharm. Soc. Japan), 1921, [468], 125—130.

Pure α-monobromoisovalerylurea (bromural) melts at 154° C., whilst commercial samples melted at 145°—157° C. The difference is due mainly to the presence of methylethylbromoacetylurea and isovalerylurea. The melting-point curve of mixtures of bromural and isovalerylurea has a minimum, and hence the same melting point may correspond to two different mixtures. To ascertain the purity of bromural, determination of the melting point is, therefore, of no value, and the bromine content should be determined.—K. K.

Hydrogenation; A catalytic method of ——. J. Nivière. Bull. Soc. Chim., 1921, **29**, 217—219.

The material to be hydrogenated, dissolved in a suitable solvent, is placed in a stout-walled bottle. A small amount of a solution of palladium chloride or platinum chloride is added to act as a catalyst, and then the calculated amount of calcium hydride is added gradually, the flask being stoppered and well shaken. This method was used successfully for the reduction of benzaldehyde, nitrobenzene, and benzylidene-acetone.—W. G.

Phenylhydrazones; Catalytic hydrogenation of ——. A. Mailhe. Comptes rend., 1921, **172**, 1107—1110.

Phenylhydrazones are hydrogenated when passed

in a rapid current of hydrogen over reduced nickel at 180°—190° C. If derived from aldehydes they give aniline and the corresponding nitrile, but if derived from ketones they yield aniline, the primary amine, and some secondary amine.—W. G.

Benzoic acid; Synthesis of chlorine-free —— from benzene. R. H. McKee and F. A. Strauss. Chem. and Met. Eng., 1921, **24**, 638—644, 697—702.

The reactions involved in the conversion of sodium benzenesulphonate into benzoic acid were investigated with a view to their utilisation on a commercial scale. Experiments on the direct formate fusion method indicated that benzoate formation only takes place at a high temperature and is accompanied by much decomposition. Synthesis through benzonitrile gave greater promise of success on the technical scale. The main reaction in which benzonitrile is formed is accompanied by side reactions of two general types—reduction of the sodium benzenesulphonate by sodium cyanide, and decomposition of the cyanate formed, by water vapour, with formation of sodium carbonate, carbon dioxide and ammonia, and secondly pyrogenic decomposition of the benzenesulphonate with production of a large number of substances including thioethers, thiophenols, hydrogen sulphide, etc. The most favourable reaction conditions for the formation of the maximum yield of benzonitrile were shown to be: Temperature of the reaction mixture must be kept between the limits of 420°—430° C.; finely powdered cyanide and sulphonate intimately mixed in equimolecular proportions, or a slight excess of cyanide; addition to the mixture of sand or other inert material, an admixture of 70% of 40-mesh sand being the optimum. Under these conditions a nitrile formation efficiency of about 43% was obtained. Reducing the pressure did not improve this result, but rather favoured the formation of sulphur compounds and tar. Hydrolysis of benzonitrile by sulphuric acid (sp. gr. 1·6) was more rapid and efficient than alkali hydrolysis, and gave yields amounting to about 95% of the theory of practically pure benzoic acid. With a source of cheap cyanide the authors consider that the process proposed would produce benzoic acid of a higher degree of purity and at a lower price than the methods at present in use.—G. F. M.

p-Aminophenol; Electrolytic manufacture of ——. A. S. McDaniel, L. Schneider, and A. Ballard. Trans. Amer. Electrochem. Soc., 1921, 319—327. [Advance copy.]

Nitrobenzene was reduced electrolytically at 30° C. in strong sulphuric acid (90—91%), free from iron and heavy metals, using platinum electrodes, with a cathode current density of 6—8 amp. per 100 sq. cm., and anode density double. Glazed earthenware cells with porous diaphragms of thin, dense porcelain were used. Under these conditions minimum sulphonation was obtained. By washing the cell sludge with commercial hydrochloric acid, centrifuging, and treating with pure hydrochloric acid *p*-aminophenol hydrochloride was obtained, the yield being 40—50% on the nitrobenzene (exclusive of mother liquors which yield a further 10%). Apart from the cost of platinum, the most important economic factor is the necessity of providing for the cheap concentration of the spent acid. Cost of upkeep, owing to the excessive corrosive action of the materials on the apparatus, is also considerable.—P. V. M.

Phenoxarsine; Derivatives of ——. W. L. Lewis, C. D. Lowry, and F. H. Bergeim. J. Amer. Chem. Soc., 1921, **43**, 891—896.

6-Chlorophenarsazine, m.p. 193° C., has a greater irritant action on the skin and mucous membrane and is more toxic than diphenylchloroarsine, m.p. 37°—38° C., b.p. 333° C., which in turn is more irritant and toxic than 6-chlorophenoxarsine, $O(C_6H_4)_2AsCl$, m.p. 124° C., or chlorophenyl-α-naphthylarsazine, m.p. 228° C. The chlorine in 6-chlorophenoxarsine may readily be replaced or displaced, and a number of new compounds have been prepared from it. (*Cf.* J.C.S., June.)—W. G.

Chlorovinylchloroarsines. S. J. Green and T. S. Price. Trans. Chem. Soc., 1921, **119**, 448—453.

Three products are formed when acetylene acts upon anhydrous arsenic trichloride in the presence of anhydrous aluminium chloride, either in the pure state or in solution in an anhydrous solvent, at 15° C. β-Chlorovinyldichloroarsine, $CHCl:CH.AsCl_2$, colourless, b.p. 93° C. at 26 mm., or 96° C. at 30 mm., possesses a powerful vesicant action. ββ′-Dichlorodivinylchloroarsine, $(CHCl:CH)_2AsCl$, b.p. 130°—133° C. at 26 mm., colourless, possesses less powerful vesicant action than the primary compound. ββ′β″-Trichlorotrivinylarsine, $(CHCl:CH)_3As$, colourless, b.p. 151°—155° C. at 28 mm., m.p. 3°—4° C. All are insoluble in water and dilute acids, but are soluble in organic solvents, with the exception of the tertiary compound which is insoluble in alcohol. Halogens are readily absorbed with the formation of definite characteristic solid compounds. The tendency is for the tertiary derivative to be formed largely at the expense of the others, but it is readily changed to a mixture of the primary and secondary compounds by heating with arsenic trichloride at 200°—250° C. —P. V. M.

ββ′-Dichlorodiethyl disulphide. G. M. Bennett. Trans. Chem. Soc., 1921, **119**, 418—425.

ββ′-Dichlorodiethyl disulphide is synthesised through dihydroxydiethyl disulphide from either monothioethyleneglycol by oxidation with potassium permanganate etc., or from ethylene chlorhydrin and sodium disulphide. Heating with concentrated hydrochloric acid converts the dihydroxy compound into ββ′-dichlorodiethyl disulphide, b.p. 15° C. at 30 mm., sp. gr. 1·3375 at 20°/4° C. The pure disulphide closely resembles the monosulphide in properties, but has only one-third its vesicant action. Oxidation with nitric acid gives quantitatively β-chloroethanesulphonic acid. In the light of his results the author discusses the condition of the system arising from the interaction of sulphur monochloride and ethylene, and concludes that the liquid produced at temperatures below 35° C. is a two-phase system in which the continuous phase is nearly pure dichlorodiethyl monosulphide and the disperse phase a liquid consisting chiefly of sulphur. —P. V. M.

Sulphur monochloride and substituted ethylenes; Interaction of ——. W. J. Pope and J. L. B. Smith. Trans. Chem. Soc., 1921, **119**, 396—400. (*Cf.* Gibson and Pope, J., 1920, 383 A.)

From an examination of the interaction of ethylene, propylene, and β-butylene with sulphur monochloride, it is shown that the formation of the corresponding β-chloro-substituted alkyl sulphide and sulphur is general for ethylenic hydrocarbons. ββ′-Dichlorodipropyl sulphide $(C_2H_4Cl.CH_2)_2S$ boils at 105°—106° at 11 mm., and ββ′-dichlorodi-*sec*-butyl sulphide $(CHCH_3Cl.CHCH_3)_2S$, at 121°—122° at 11 mm. The speed of absorption varies in each case, and of the three substances examined is greatest for β-butylene. Under comparable conditions the speed of absorption, *i.e.*, the rate of interaction, is represented by ethylene:propylene:β-butylene=1:1·33:4. No analogous reaction was obtained between sulphur monochloride and trichloroethylene, the sulphur monochloride acting merely as a chlorinating agent with the formation of pentachloroethane.—P. V. M.

Mercaptans; Catalytic preparation of ——. R. L. Kramer and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 880—890.

By passing alcohol vapour and hydrogen sulphide in equimolecular proportions at the rate of 1 g.-mol. in 6 hrs. over pumice coated with thorium oxide at 380° C., the following percentage yields of mercaptans were obtained: methyl 41%, ethyl 35%, propyl 45%, butyl 52%, isobutyl 45%, isoamyl 47%. Propyl, butyl, and isoamyl mercaptans give constant boiling mixtures with the corresponding alcohols and ternary mixtures with the alcohols and water. (*Cf.* J.C.S., June.)—W. G.

Acrolein. C. Moureu, C. Dufraisse, A. Lepape, P. Robin, J. Pougnet, A. Boutaric, and E. Boismenu. Ann. Chim., 1921, **15**, 158—211.

A MORE detailed account of work already published. (*Cf.* J., 1920, 42 A, 82 A, 173 A.)—W. G.

Formaldehyde; Distillation of aqueous solutions of ——. J. A. Wilkinson and I. A. Gibson. J. Amer. Chem. Soc., 1921, **43**, 695—700.

THE distillate from dilute aqueous solutions of formaldehyde (below 8%) is always stronger than the original solution, but with higher concentrations the distillate is always weaker. With low concentrations the residue is always weaker than the last distillate, but with high concentrations the residue is always stronger.—J. F. S.

Cyanamide; Passage from guanidine to —— *and from diguanidine to dicyanodiamide.* G. Pellizzari. Atti R. Accad. Lincei, 1921, [V], **30**, I., 171—175.

VARIOUS reactions similar to the conversion of *o*-phenylenediguanide into β-cyano-*o*-phenyleneguanidine by treatment with nitrous acid (Atti R. Accad. Lincei, 1921, [V], **30**, I., 39) have been discovered. Thus, nitrous acid converts diguanide into cyanoguanidine or dicyanodiamide, and guanidine partly into cyanamide. In the latter case, the formation of nitrosoguanidine as an intermediate compound has been detected and it is probable that in the other instances analogous intermediate products are formed. (*Cf.* J.C.S., June.)—T. H. P.

Cyanogen bromide and iodide; Preparation of ——. V. Grignard and P. Crouzier. Bull. Soc. Chim., 1921, **29**, 214—217.

AN aqueous solution of sodium cyanide is run slowly on to bromine covered with a small amount of water, with constant stirring, the temperature not being allowed to rise above 25° C., until the colour due to the bromine has disappeared. Chlorine is then bubbled through the liquid and, at the same time, more sodium cyanide is run in, drop by drop, keeping the liberated bromine in slight excess, until the whole of the sodium bromide originally formed is decomposed, when a very slight excess of the cyanide is added. The cyanogen bromide, which crystallises out, may be filtered off, or the contents of the flask may be distilled, the vapour being passed over anhydrous calcium chloride at 80° C. A yield of 91% is obtained. Cyanogen iodide may be prepared in a similar manner, but it is best isolated by extraction with ether. A yield of 89% is obtained.—W. G.

Essential oil of hamagô. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 191-202.

BY the distillation of the leaves and twigs of *Vitex trifolia*, L. (*Vitex ovata*, Mak.?) (Jap., hamagô), grown in the Ogasawara Islands and Kanagawa Prefecture, 0·11—0·28% of an oil having a brown colour and characteristic odour was obtained. Three samples of the oil had the following characters:—Sp. gr. at 15° C., 0·8908—0·9141; n_D^{20}= 1·4707—1·5010; optical rotation, −39° 6′ to −47° 20′; acid value, 0·0—1·75; saponif. value, 23·38—38·70; saponif. value after acetylation, 40·14—53·34. The chief constituents of the oil were *l*-α-pinene, which does not give solid nitrosochloride; camphene (percentage with pinene: 55%); terpinyl acetate (10%), b.p. 84°—86° C. at 15 mm., sp. gr. 0·9629 at 15° C., n_D^{20}=1·4670; a diterpene-alcohol ($C_{20}H_{32}O$ or $C_{20}H_{34}O$) (20%), b.p. 165°—167° C. at 4 mm., sp. gr. 0·9760 at 15° C., n_D^{20}=1·5143, optical rotation, −46° 39′, and saponif. value after acetylation 42·02. The oil is separated into its three chief constituents by fractional distillation, and the middle part is suitable for perfumes, as it is mainly composed of terpinyl acetate.—K. K.

Essential oil of shimamuro. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 202—208.

BY distillation of the leaves and twigs of *Juniperus taxifolia*, Hook. et Arn. (Jap., shimamuro), a coniferous plant, indigenous to the Ogasawara Islands, 0·24% of a light green oil was obtained. Two specimens of the oil had the following characters:—Sp. gr. at 15° C., 0·8675, 0·8701; n_D^{20}=1·4702, 1·4718; optical rotation, —, −29°; acid value, 0·94, 0·0; saponif. value, 11·69, 10·37; saponif. value after acetylation, 19·60, 18·89. The oil contains α-pinene (above 50%, mainly *l*-α-pinene containing small quantity of *r*-α-isomer) and possibly a bicyclic terpene, a free alcohol ($C_{10}H_{18}O$), ester, sesquiterpene, and sesquiterpene alcohol.—K. K.

PATENTS.

Dichloroethylene; Manufacture of ——. A. Wacker, Ges. für Elektrochem. Industrie. E.P. 156,080, 22.10.20. Conv., 23.12.19.

DICHLOROETHYLENE is obtained in 85—88% yield by passing the vapour of tetrachloroethane mixed with steam through a chamber charged with iron, aluminium turnings, or granulated zinc. The crude product issuing from the chambers is condensed and fractionally distilled, the fraction collected between 48° and 60° C. being a mixture of two stereo-isomeric dichloroethylenes. The small higher fraction of unchanged tetrachloroethane is returned to the process.—G. F. M.

Tubercle bacillus and other germs; Detoxication of —— *for the preparation of vaccines.* D. Thomson. E.P. 161,341, 23.1.20.

THE germ cultures are separated into a number of non-toxic fractions by successive extractions with either "antiformin" (15% sodium hydroxide plus 15% sodium hypochlorite solution) or *N*/1 sodium hydroxide, *N*/1 hydrochloric acid, absolute alcohol, and chloroform. The insoluble matter is separated after each extraction by centrifuging, and the clear solution is removed for further treatment. The portions extracted by the alkaline and acid solutions are again fractionated by precipitating a portion of the dissolved material with acid and alkali respectively, and subsequently adding absolute alcohol to the liquors to precipitate second fractions. The alcohol extract is precipitated by the addition of normal aqueous sodium chloride, and the final portion extracted with chloroform is recovered by evaporating the solvent. The precipitates are mixed together, with the exception in certain cases of the fractions precipitated by alcohol from the alkali and acid extracts, which possess provocative properties, and are emulsified with normal sodium chloride solution containing 0·5% of phenol,

to yield a vaccine corresponding to ten thousand millions of germs per c.c.—L. A. C.

Allyl esters of p-aminobenzoic acid. R. Adams and E. H. Volwiler, Assrs. to The Abbott Laboratories. U.S.P. 1,360,994, 7.12.20. Appl., 10.5.20.

ALLYL esters of amino derivatives of aromatic acids containing a benzene nucleus are prepared by reduction of the corresponding nitro derivatives. The allyl ester of *p*-nitrobenzoic acid, prepared from *p*-nitrobenzoyl chloride and allyl alcohol, boils at 178° C. at 19 mm., and on reduction yields the allyl ester of *p*-aminobenzoic acid, white crystals, m.p. 51°—52° C., of value as an anæsthetic. The dihydrochloride of the allyl ester of 3.5-diaminobenzoic acid is a yellowish solid, m.p. 224° C. (decomp.).

Phenylcinchonic acid salt. M. E. Wolvecamp, Assr. to The Abbott Laboratories. U.S.P. 1,361,128, 7.12.20. Appl., 15.9.17.

ACID sodium phenylcinchonate, $C_{16}H_{10}NO_2Na$, $C_{16}H_{11}NO_2$, prepared by the action of the calculated quantity of sodium hydroxide solution on the acid and dried below 100° C., forms citron-yellow crystals, freely soluble in water and exhibiting the same medicinal properties as the free acid.

Acetylation of hydrocarbons and subsequent recovery of the products of the reaction. G. T. Koch and A. L. Stallkamp, Assrs. to The Ohio Fuel Supply Co. U.S.P. 1,374,666, 12.4.21. Appl., 4.11.20.

CHLOROHYDROCARBONS of the paraffin series are converted into acetates (*e.g.*, amyl acetate) by heating at 250°—450° F. (120°—230° C.) under a pressure of 200—225 lb. per sq. inch with an alkali acetate in presence of activated carbon or "batchite" as a catalyst. The product is fractionally distilled and the lower fractions returned to a subsequent operation.—G. F. M.

Organic compounds; Preparation of —— by chemical reactions promoted by light. Farbenfabr. vorm. F. Bayer und Co. G.P. 297,933, 25.6.15.

THE light of the Osram half-watt lamp is used, which is nearly equivalent to sunlight in its chemical effect. Examples are the preparation of xylyl chloride from xylene, pinacone from acetone and isopropyl alcohol, etc.—C. I.

Cyanamide; Preparation of solutions rich in —— from calcium cyanamide. A.-G. für Stickstoffdünger. G.P. 302,515, 5.11.16.

CALCIUM cyanamide is extracted with water and the solution treated with carbon dioxide or absorbing materials, *e.g.*, earth or peat, to remove the lime. The resulting liquor containing 2—3% N is used to extract further quantities of calcium cyanamide. No polymerisation of the cyanamide in solution takes place during the operation. —A. R. P.

Alkali cyanamides; Process for preparing ——. Preparation of alkali cyanamide solutions. E. Hene and A. van Haaren. G.P. (A) 306,315, 28.9.16, and (B) 307,011, 17.11.16.

(A) CALCIUM cyanamide and alkali sulphate are allowed to interact at temperatures below 100° C., preferably 25°—35° C., in water. Excess of alkali sulphate reduces the amount of calcium cyanamide left in solution, but a double sulphate is then formed. (B) Instead of alkali sulphate a double alkali-calcium sulphate may be used. To a weak solution of alkali cyanamide, calcium cyanamide and sufficient alkali sulphate to form mono-alkali cyanamide along with a double sulphate are added. The resulting mud is used with more calcium cyanamide and water to form fresh weak solution, and the mono-alkali cyanamide which still contains calcium is treated with fresh alkali sulphate. —C. I.

Fatty acids and aldehydes; Process for the preparation of ——. C. Harries, R. Koetschau, and E. Albrecht. G.P. 332,594, 23.3.17. Addn. to 324,663 (J., 1920, 765 A).

OZONIDES prepared from petroleum, shale oil, or tar oils or the compounds formed by their reaction with water vapour or alkali are treated with oxidising agents, *e.g.*, hydrogen peroxide and alkali, Caro's acid, halogens, chromic acid, glacial acetic acid and permanganate.—C. I.

5(4)-Aralkylaminoalkyliminazoles; Manufacture of ——. O. Gerngross. G.P. 332,955, 10.6.14. Addn. to 278,884 (J., 1915, 250).

COMPOUNDS of the general formula, iminazolyl. $(CH_2)_X.NH.(CH_2)_X.$aryl are prepared by the interaction of iminazolylalkyl chlorides and aralkylamines or aralkyl chlorides, Ar.$(CH_2)_X$.Cl and iminazolealkylamines, or the salts of the compounds respectively. By interaction of 4(5)-methyl-5(4)-chloromethyliminazole hydrochloride and β-phenylethylamine, a mixture of secondary 4(5)-methyl-5(4)-phenylethylaminomethyliminazole and tertiary di-5(4)-methyliminazolyl-4(5)-methyl-β-phenylethylamine is obtained. They are separated by fractional crystallisation of their picrates from acetone, the picrate of the tertiary base being more soluble. By heating β-*p*-hydroxyphenylethyl chloride with β-4(5)-iminazolylethylamine in dry methyl alcohol for 12 hrs. at 100° C. under pressure, 4(5).4'-hydroxyphenylethylaminoethyliminazole, $OH.C_6H_4(CH_2)_2.NH.(CH_2)_2C_3H_3N_2$, is formed. It melts at 156° C. and is slightly soluble in water. The compounds have a physiological effect similar to that of ergot.—C. A. C.

Formic acid esters; Preparation of ——. Elektrochem. Werke G.m.b.H., H. Bosshard, and D. Strauss. G.P. 334,298, 19.11.16.

FORMIC acid and alcohols of the highest concentration practicable are caused to react in the theoretical proportions in presence of calcium chloride without addition of mineral acids. The apparatus may be made of iron, and the calcium chloride recovered.—C. I.

Hexamethylenetetramine; Preparation of addition products of ——. J. D. Riedel A.-G. G.P. 334,709, 31.12.18.

IF a mixture of hexamethylenetetramine and monohalogen-acetic acid, in an anhydrous solvent, is heated, the salt first formed is converted into a substance resembling betaine hydrochloride. The presence of a little water or the use of halogenated higher fatty acids leads to the formation of hexamethylenetetramine-halogen hydrate. The addition products from monochloro- and monobromoacetic acids are coarsely crystalline substances, easily soluble in water, slightly in alcohol, and insoluble in acetone and ether. On crystallisation from aqueous alcohol the halogen hydrate compound is formed. The aqueous solution, which tastes acid, evolves formaldehyde on heating. The substances are strong bactericides.—B. V. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plate; Extinction by a blackened —— as function of wave-length, quantity of silver, and size of the grains. A. Deumens. Proc. Roy. Acad. Amsterdam, 1921, 23, 848—865.

Two series of plates were prepared, one set developed with varying times, or temperature, or developer strength, in a caustic quinol developer

and the other set with similar variations in a glycin developer. All the plates were examined as to density, amount of silver, and grain size. The density value was found to vary with the wavelength of the light by which it was measured to an extent which varied with the conditions of development, this being one of the factors determining grain size. Plates developed in a normal glycin developer were practically neutral in colour in the yellow-green portion of the spectrum and suitable therefore for use as reducers of light intensity in photometric measurements etc. using yellow-green light. The relation between quantity of silver and density is shown to vary with grain size. It is suggested that the proportionality (photometric constant) previously found by Hurter and Driffield, Sheppard and Mees, and Eder was due to their use of silver images with grains of equal size. Some figures are also given for collargol.—B. V. S.

[Photographic] red sensitiveness of silver iodide. R. B. Archey. Phot. J., 1921, **61**, 235—236.

In using various cinematograph positive films a considerable variation in the ease of fogging by the dark-room light was observed, both between different brands of film and between different emulsions of the same manufacture. Film was exposed 30 mins. to a 25 c.p. lamp behind a Wratten No. 1 safelight at a distance of 1 ft., and developed under constant, normal conditions. The resulting density measured on a König-Martens photometer was found to be proportional, not to the speed of the plate, but to the contrast. In one case the same film was tested at intervals of 1 month for 9 months, the H. and D. speed, developing factor, and red sensitiveness being determined; changes in the two latter corresponded but not with changes in speed. The addition of excess iodide in the manufacture of an emulsion in one case led to a fog value of 2·72. Spectrograms of two films are given at either end of the spectrum in each case, the two spectra at the blue end being practically indistinguishable, while at the red end one film shows no image and the other a very strong one.—B. V. S.

Patents.

[Photographic] toning-baths for silver-pictures, with tellurium or selenium as the toning agent. Kraft und Steudel, Fabr. phot. Papiere, G.m.b.H. G.P. 334,172, 1.6.20.

In the preparation of toning baths containing a selenium or tellurium salt as toning agent, other known toning agents such as thiourea, hydrazine, or hydroxylamine may be added, along with a salt such as a borate or phosphate, or preferably, acetate, citrate, tartrate, etc., which prevents precipitation of the selenium or tellurium. A bath prepared with tellurous acid and an alkali, such as lithium hydroxide, is preferably acidified. The stability of a toning bath may be increased by the addition of a protective colloid such as albumin or starch. The developed, fixed, and washed print is toned for 3—15 mins. according to the tone required; chloride prints tone more quickly and require a weaker bath. Selenium gives redder tones than tellurium.—B. V. S.

Coloured [photographic] pictures; Process for making ——. A. Traube. E.P. 147,103, 7.7.20. Conv., 3.12.18. Addn. to 147,005.

Basic dyes of the thiobenzenyl, thiazine, pyronine, safranine, oxazine, and acridine classes give better results than the dyes mentioned in the chief patent (J., 1921, 325 A), by reason of their greater permanence in the toning processes, combined with easy staining and sufficient colour intensity.—B. V. S.

Photographic reproduction; Process of ——. R. John, Assr. to Iconochrome Co. of America, Inc. U.S.P. 1,374,853, 12.4.21. Appl., 25.7.19.

For the production of a transfer printing plate an emulsion is used containing in addition to the light-sensitive material a substance which reacts with the product of light action on the sensitive material to form a hardening agent, and a further substance having a neutralising effect on the hardening agent which is added in sufficient proportion to make the amount of hardening proportional to the amount of image.—B. V. S.

Photosensitising dye of the isocyanine type. Photosensitising dye effective for infra-red radiation. E. Q. Adams and H. L. Haller. U.S.P. (A) 1,374,871 and (B) 1,374,872, 12.4.21. Appl., 28.5 and 17.7.20.

(A) Photosensitising dyes are produced by the action of strong bases in alcoholic solution upon the alkyl halides of lepidine. (B) The dyes obtained from the higher alkyl halides of lepidine give sensitiveness in the infra-red. (*Cf.* J., 1921, 75 A.) —B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Corn [maize] cob cellulose; Possible uses of —— *in the explosives industry.* L. G. Marsh. J. Ind. Eng. Chem., 1921, **13**, 296—298.

Cellulose extracted from maize cobs by treatment with 1% sodium hydroxide, and then 4% sulphuric acid, at 100° C., absorbs 150% of its own weight of nitroglycerin, and is therefore a suitable ingredient for dynamite. In preliminary tests of its absorptive capacity for water, with a view to employing it as a substitute for cotton in nitrocellulose manufacture, samples were totally submerged in less than 12 secs. after dropping on the surface of the water. Some difficulty was experienced in separating nitrated maize cob cellulose from the acid on account of its fineness; screening was ineffective, and it was finally separated by gravity, a mat of nitrated cotton being used. Washing and settling were carried out satisfactorily; pulping was unnecessary, but the usual purification system could be adopted. A yield of about 130% was obtained. The product gave a satisfactory heat test. The nitrogen content was only 12·3%, due to a high proportion of material insoluble in acetone; after removing this, the nitrogen figure was increased to 12·7%. Even by nitrating equal parts of cotton and maize cob cellulose, no material reduction was effected in the acetone-insoluble residue; its structure, consisting of fine, hard grains, militates against the use of maize cob cellulose for the manufacture of perforated powders.—W. J. W.

Trinitrotoluene poisoning; Nature, diagnosis, and prevention of ——. C. Voegtlin, C. W. Hooper, and J. M. Johnson. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 7—181.

Numerous tests were made on dogs, which are more sensitive than other animals, and develop the typical symptoms noted with human beings. The toxic action of TNT is essentially due to 2.4.6-trinitrotoluene, and not to impurities. As indicated by Moore (Causation and Prevention of Trinitrotoluene Poisoning, Medical Research Committee, London. 1917), TNT is not excreted as such, but is converted after absorption into a hydroxylamine compound. This compound may also undergo reduction to the mono- or diamino-derivative which do not give the Webster reaction but have the same pharmacological action as TNT. Differences in resistance of different individuals may be due to the fact that more resistant animals oxidise the methyl

group of TNT more readily. Reliance on clinical symptoms alone in the diagnosis of TNT poisoning in munition workers is not sufficient, as marked blood changes may be present, even when the workers do not exhibit signs of cyanosis, pallor, or icterus; an examination of the blood is therefore essential. Sex has no influence on susceptibility to poisoning, and individual susceptibility, as with dogs, explains the absence of relation between time of exposure to the poison and contraction of anæmia. The authors do not concur with Moore's view that all TNT poisoning is caused by skin absorption, and that individual susceptibility is accounted for by difference in skin permeability. Preventive measures should include efficient ventilation and the use of induced draught for cleaning floors, etc. Overalls extending over the ankles and a head-dress should be worn; gloves are useless. A skin wash of 10% sodium sulphite solution has proved satisfactory. Workers' diet should include a fair proportion of meat, vegetables, bread, and fruit. Although to a certain extent intermittent employment reduces the health risk, it does not entirely prevent poisoning, as the system retains TNT for a long time. Workers should undergo a preliminary medical examination, and none suffering from anæmia or liver disease should be employed. —W. J. W.

Parazol (crude dichlordinitrobenzene); Toxicity of ——. C. Voegtlin, A. E. Livingston, and C. W. Hooper. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 183—202.

Parazol, which was extensively used as a high explosive during the war, is a mixture of three isomers: *m*-dinitro-*p*-dichlorobenzene, *o*-dinitro-*p*-dichlorobenzene, and *p*-dinitro-*p*-dichlorobenzene; in addition, a small fraction consisting of *p*-nitrochlorobenzene has been separated from it. The action on the skin of crude and recrystallised parazol, as well as of two of its isomers and of *p*-nitrochlorobenzene, was studied with rabbits, and confirmed in some cases with human skin. In each case dermatitis was produced. More severe lesions were caused by the crude product than by its isomers, and of these latter the *m*-dinitro compound proved more injurious than either the *o*-dinitro compound or *p*-nitrochlorobenzene. In regard to the action on the eyes, no effect was produced when the products were applied as a 1% solution in olive oil; on the other hand, the dry powder caused marked conjunctivitis; that this result was not due merely to mechanical irritation was proved by the varying effect produced by the different products, crude parazol being the most active. Crude parazol when injected subcutaneously caused extensive edema and induration, sometimes leading to the formation of an abscess. When introduced through the mouth it was absorbed without gastro-intestinal irritation. Relatively large amounts of parazol are required to produce anæmia, and it may therefore be regarded as a low grade poison. The active agents in causing anæmia are probably the nitro-groups, which, as with TNT, become reduced in the body. On the other hand, dermatitis and conjunctivitis depend on the presence of chlorine in the molecule. To protect parazol workers contamination of the air with the material should be prevented, and goggles should be worn. The provision of proper overalls is essential; skin varnishes are unreliable.—W. J. W.

Mercury fulminate; Skin irritation and systemic effects produced by ——. A. E. Livingston. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 203—211.

Application of mercury fulminate to the shaved skin of rabbits invariably caused a marked lesion after 2—3 hrs., and blanching of the skin took place, followed by endema; after a longer period a hemorrhagic condition replaced the blanching. Applications of fulminate to the human skin produced no effect whatever, but no conclusion can be drawn from this as to its effects on workers in factories, where friction, lack of cleanliness, etc., may cause the poison to enter the skin, and where individual susceptibility has an important bearing. In regard to the systemic effects of mercury fulminate, there is no evidence of fatal results brought about by absorption through the skin, nor could it be detected in the urine, after skin application. When administered as capsules through the mouth the minimum lethal dose for rabbits appears to be about 20 mg. per kg. As a preventive measure against fulminate poisoning, a shellac skin varnish has given good results. Sodium thiosulphate solution is beneficial if used as a wash; it is, however, useless for treatment after injury.—W. J. W.

Detonators and percussion caps; Examination of ——. A. Langhans. Z. ges. Schiess- u. Spreng-stoffw., 1921, 16, 49—52, 57—59.

Microscopical examination of cap and detonator compositions affords a means of identifying their components. In a quantitative examination the risk involved in removing the composition from its metal container is avoided by submitting the whole detonator or cap to solution and analysis. The author describes a method of analysis. The composition of the caps was as follows: Mercury fulminate, 0·054 g. (mercury, 0·038 g.); antimony sulphide, 0·208 g.; potassium chlorate, 0·339 g.; powdered glass, 0·013 g.; potassium nitrate, 0·0684 g.; sulphur, 0·0081 g.; carbon, 0·0135 g.; copper, 0·79 g. Four caps were treated for 2 hrs. with a mixture of 50 c.c. of nitric acid and 25 c.c. of water. The solution was evaporated to dryness, and the residue boiled three times with dilute nitric acid, and filtered; powdered glass, together with some charcoal and sulphur, remained on the filter. After dilution of the filtrate to 500 c.c., 100 c.c. was treated with hydrogen sulphide; the precipitate was treated with sodium sulphide solution and potassium hydroxide, and the solution filtered from the undissolved copper sulphide, which was dissolved in acid and electrolysed. The filtrate containing sulphides of antimony and mercury in solution was acidified, and the precipitated sulphides filtered off and treated with ammonium sulphide for a prolonged period; the antimony sulphide was precipitated with sulphuric acid, whilst the undissolved mercury sulphide was dissolved in nitric acid and electrolysed. For the estimation of potassium chlorate and nitrate the filtrate from the original hydrogen sulphide precipitation was evaporated to expel hydrogen sulphide, and the residue then treated with water and sulphuric acid and again evaporated to dryness. From the potassium sulphate found the respective amounts of chlorate and nitrate were calculated. For the analysis of detonators an analogous method to the above may be employed. For mercury fulminate and potassium chlorate compositions a method of estimating chlorate by the use of nitron is also applicable.—W. J. W.

Patents.

Explosives [for detonators]. A. G. Lowndes. E.P. 160,953, 6.1.20.

The sensitiveness of explosives, such as lead azide, is said to be due more to the structure and cleavage than to the size of the crystals. By adding a non-colloidal solution, which has no action on lead azide, to the liquid in which it is precipitated so as to increase the density of the liquid, the azide may be obtained in the form of anhedra, flakes, or thin plates, of less sensitiveness than the holohedra usually formed. Thus, 200 c.c. of sodium azide solution (40 g. per l.) is added to a mixture of

200 c.c. of lead acetate solution (117 g. per l.) and 1000 c.c. of sodium nitrate solution (450 g. per l.), all at 15° C. Alternatively, equivalent solutions of sodium azide and lead acetate may be run into sodium nitrate solution. (*Cf.* E.P. 142,898; J., 1920, 529 A.)—W. J. W.

Explosive; High —— and process of making same. W. R. Swint, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,373,844, 5.4.21. Appl., 6.5.18.

An explosive composition consists of wet nitrocellulose of a high degree of nitration and a liquid nitro-derivative of a hydrocarbon.—W. J. W.

Explosive. G. Weber, Assr. to Soc. Les Petits Fils De Francois De Wendel et Cie. U.S.P. 1,375,243, 19.4.21. Appl., 27.9.19.

An explosive contains a combustible organic substance adapted to absorb liquid air, and blast-furnace dust.—L. A. C.

Detonators; Process for destroying waste —— and recovering copper and mercury from the same. W. Eschbach. G.P. 298,860, 29.11.16.

The detonators are placed in a rotary drum, provided with a suitable shock-absorbing device, and treated with a hot solution of sodium carbonate, which loosens the composition by dissolving its potassium chlorate or perchlorate, and converts the mercury fulminate into mercuric carbonate and sodium fulminate. After filtering and washing this mixture the mercury is recovered from it electrolytically. The empty shells are washed and introduced in small quantities into a furnace in which any remaining traces of explosive are decomposed.
—W. J. W.

Mixed acid; Process for preparing ——. Chem. Fabr. Griesheim-Elektron. G.P. 303,892, 1.3.16.

Dilute nitric acid is absorbed, *e.g.*, in a tower, by a counter current of cooled concentrated sulphuric acid.—C. I.

Ammonium nitrate and carbon; Process of obtaining mixtures of —— which can be cast. Verein Chem. Fabr. in Mannhein. G.P. 309,288, 5.9.17.

Wood charcoal of a definite, not too low adsorptive power and water content, is mixed with ammonium nitrate. The melting point of the mixture is lowered by the addition of carbon or oxygen compounds; *e.g.*, 15 pts. of finely powdered wood charcoal is saturated with 25% of its weight of water, then mixed with 77 pts. of ammonium nitrate and 8 pts. of sodium nitrate, the mixture heated to 110° C., and cast in the desired shape.—C. I.

XXIII.—ANALYSIS.

Viscosimeter. R. Fischer. Z. angew. Chem., 1921, **34**, 153—154.

The tube of a falling-sphere viscosimeter described previously by the author (Chem.-Zeit., 1920, **44**, 622) may be widened so that the path of the sphere is not affected by the tubulus for the thermometer; the apparatus may be standardised with different sized spheres for use with liquids of low and high viscosities, and, when dealing with aqueous liquids, the electrical contacts at the bottom of the tube may be covered with a layer of carbon tetrachloride which is introduced before the liquid.—W. P. S.

Combustion analysis by means of tellurium dioxide. T. R. Glauser. Z. angew. Chem., 1921, **34**, 154—155, 157—159, 162—163.

A record of further work on a method described previously (J., 1914, 223). Whilst the carbon in many substances (*e.g.*, iron, heavy metals, graphite) is oxidised readily to carbon dioxide by heating with tellurium dioxide, the reaction proceeds very slowly in the case of ferrosilicon, carborundum, etc., and for the determination of carbon in these it is better to use lead oxide or a mixture of lead oxide and tellurium dioxide as the oxidising agent.
—W. P. S.

Refractive indices of liquids; Simple instrument for the determination of the ——. W. A. M. Smart and F. A. Hocking. Pharm. J., 1921, **106**, 286—288.

A vertical rod, fixed to a wooden base, carries a sliding device to which is attached an observation lens; a piece of hat-pin is also attached to the sliding device below the lens so that its end is vertically below the centre of the lens. A thin mirror is let into the base and a convex lens of +6D to +10D is laid on the mirror. The slider is raised or lowered until the pin and its image (as seen by reflection from the mirror and through the lens) are exactly coincident. The distance between the pin and the centre of the lens is then read off on a scale fixed to the vertical rod. A few drops of water are then placed between the mirror and the lens and the new focal position read off after adjusting the slider. This operation is repeated, using the liquid the refractive index of which is to be determined in place of the water. The refractive index, μ_2, of the liquid is then calculated by the formula, $\mu_2 = \mu(f-F_2)F_1 + (F_2-F_1)f / F_2(f-F_1)$, where μ is the refractive index of water, f the focal length of the lens when air is between it and the mirror, F_1 the focal length of the water-lens combination, and F_2 that of the liquid-lens combination, these lengths being read in mm. on the scale.—W. P. S.

Enamelled bombs; Use of —— in calorimetry. C. Matignon and G. Marchal. Comptes rend., 1921, **172**, 921—922.

Enamelled bombs of recent manufacture are likely to be attacked by the dilute nitric acid, such as is always formed under the ordinary conditions of calorimetric work. To obviate this source of error new bombs should be filled with $N/1$ nitric acid and submitted to its action for 4—5 hrs. before being used.—W. G.

Filtration in dry or indifferent gases; Apparatus for ——. A. Wolfram. Ber., 1920, **54**, 857—859.

The apparatus permits the preparation, filtration, and desiccation of a hygroscopic substance in a single operation, with complete exclusion of moisture. The reaction vessel is a round-bottomed flask provided with a tubulus in one side by means of which a dropping funnel is attached, into which a dried gas can be passed as required. The accurately-ground neck of the flask presses a hardened filter paper against a perforated porcelain disc placed in a filter tube similar to those used with Gooch crucibles, the junction between tube and flask being made by a rubber ring. The narrow end of the filter tube is connected by a two-holed rubber stopper with a separating funnel, the other hole permitting attachment to an exhaust pump. The complete apparatus is mounted in a slightly inclined position and the reacting substances are mixed in the flask; it is subsequently brought into a vertical position, whereby the mixture flows on to the filter paper and the precipitate is filtered by suction. The filtrate is run off through the larger funnel and the precipitate is washed with liquid introduced through the smaller one. It is finally desiccated by aspirating a current of dry air or other suitable gas through it.—H. W.

Spot reactions in qualitative analysis. E. Hauser. Z. anal. Chem., 1921, **60**, 88—89.

The advantages of spot reactions on filter paper for the identification of simple substances or of mixtures, as described recently by Feigl and Stern (J., 1921, 280 A), are confirmed.—W. P. S.

Metals of the second group; Separation of ——. G. G. Longinescu and G. P. Theodorescu. Bul. Sci. Acad. Roumaine, 1920, **6**, 159—164.

THE mixed sulphides are heated with ammonium carbonate solution, and filtered; the arsenic alone is dissolved. The precipitate is then dissolved in hydrochloric acid with the addition of potassium chlorate, the solution diluted, cooled, and filtered to remove the greater part of the lead chloride. The filtrate is neutralised with sodium carbonate, sodium hydroxide is added, the mixture boiled, and filtered. Mercury, bismuth, copper, and cadmium remain in the insoluble precipitate, whilst tin, antimony, and the remainder of the lead pass into the filtrate. The precipitate is dissolved in hydrochloric acid and the solution rendered ammoniacal; mercury and bismuth are precipitated and these two metals are then separated and identified by the usual methods and tests, as are also the lead, tin, and antimony.—W. P. S.

Mercury; Identification of —— *as cuprous mercuric iodide.* P. Artmann. Z. anal. Chem., 1921, **60**, 81—88.

WHEN precipitated cuprous iodide is treated with a drop of a mercury salt solution, a bright red coloration is obtained. The test may be made on a microscope slide, or better, on filter-paper, the cuprous iodide being applied to the latter and dried at a low temperature before the mercury solution is added. The reaction may be obtained with a drop of solution containing 2 mg. of mercury per litre. The acid concentration of the mercury solution must not be greater than $N/10$, and bismuth salts and substances which are reduced readily must not be present.—W. P. S.

Iron; Determination of —— *by the cupferron method.* G. E. F. Lundell. J. Amer. Chem. Soc., 1921, **43**, 847—851.

PRECIPITATION of iron by cupferron is quantitative in hydrochloric and sulphuric acid solutions containing as much as 20% by volume of either acid. The precipitate is not dissolved by washing with cold dilute hydrochloric acid (1:9). Ammoniacal wash waters, which need rarely be employed, may cause losses. These are always indicated by the formation of turbid filtrates. Perfectly clear filtrates and washings are absolutely essential in accurate determinations of iron by the cupferron method. The precipitates occasionally exhibit a tendency to creep through the filter, consequently when the filtrate or wash water is even opalescent the need for such corrective treatments as re-filtration or digestion in the cold followed by re-filtration is indicated.—J. F. S.

Electrometric titration; Determination of iodic acid and silver by ——. W. S. Hendrixson. J. Amer. Chem. Soc., 1921, **43**, 858—866.

IODATE may be accurately determined by reducing it with a known excess of iodide in dilute sulphuric acid and titrating the excess with permanganate by the electrometric method previously described (J., 1921, 241 A). Iodides can be titrated directly with iodate in dilute sulphuric acid solution by the electrometric method. Hydrochloric acid may not be substituted for sulphuric acid except within very narrow limits of concentration in the determination of iodide with either permanganate or iodate. These estimations may be made in the presence of chloride not exceeding about $0·1N$ or in the presence of nitric acid of higher concentrations if it contains only traces of nitrous acid. Silver may be accurately determined electrometrically with pure iodide and permanganate solution. Pure silver may be used as a standard in determining the values of both iodide and permanganate.—J. F. S.

Copper; Use of silver cathodes in the electro-deposition of ——. H. W. Doughty and B. Freeman. J. Amer. Chem. Soc., 1921, **43**, 700—704.

SILVER cathodes for use in the electro-deposition of copper are cleaned by placing them in contact with pure tin-foil in a boiling 10% sodium hydroxide solution until bright. They are then washed successively with dilute hydrochloric acid, dilute ammonia, and distilled water, rinsed with alcohol, and ignited to burn off the alcohol. The electrolysis is carried out as usual except that the electrode is not immersed in the solution until the current has been switched on. To remove the copper deposit, after the final weighing, the cathode is placed in a wide-mouthed stoppered bottle filled with a 10% solution of trichloro-acetic acid in aqueous ammonia (sp. gr. 0·90) to which an equal volume of water has been added. The copper is removed in 10 mins. and the silver electrode is not attacked. Chloroform or carbon tetrachloride may be substituted for trichloro-acetic acid, but in this case the ammonia solution is made from 1 pt. of ammonia of sp. gr. 0·90 and 1 pt. of alcohol. The reaction is slower and care must be taken that no sulphur compounds are present in the carbon tetrachloride. (*Cf.* J.C.S., June.)—J. F. S.

Gold; Electrolytic determination of —— *and its separation from copper, palladium, and platinum.* W. D. Treadwell. Helv. Chim. Acta, 1921, **4**, 364—374.

GOLD may be electrolytically deposited, rapidly and quantitatively, from solutions of the chloride containing acetate, this method admitting of the separation of gold from copper, palladium, and platinum. The readiness with which palladium is attacked in comparison with platinum, when subjected to anodic polarisation in hydrochloric acid solution, serves as a means for the approximate estimation of the palladium content of a precipitate composed of a large proportion of palladium and of little platinum.
—T. H. P.

Hydrochloric acid; Detection of —— *in the presence of hydrobromic and hydriodic acids.* G. G. Longinescu and G. Chaborski. Bul. Sci. Acad. Roumaine, 1920, **6**, 122—124.

THE mixed salts are heated in a test-tube with a mixture of ethyl alcohol and concentrated sulphuric acid, an inverted funnel containing paper moistened with silver nitrate being placed over the mouth of the test-tube. The hydrochloric acid evolved together with a small amount of iodine is absorbed by the silver nitrate, and when the silver chloride is dissolved subsequently in ammonia the iodine remains insoluble. The hydrobromic acid is decomposed partially and bromoethanes are formed. If the heating is continued after all the hydrochloric acid has been expelled, the bromoethanes and iodine are evolved and may be collected by inverting a moistened beaker over the mouth of the test-tube. The beaker is then washed out with water and the solution treated with chlorine-water after the addition of carbon bisulphide; when sufficient chlorine has been added the violet coloration due to the iodine disappears and the brown coloration of the bromine remains.—W. P. S.

Nitric acid; Detection of ——. G. G. Longinescu and G. Chaborski. Bul. Sci. Acad. Roumaine, 1920, **6**, 176—178.

WHEN a nitrate is heated with a small quantity of benzene and concentrated sulphuric acid, nitrobenzene is formed, and this may be detected readily by its characteristic odour. If bromides or iodides are also present, the odour of nitrobenzene cannot be noticed until after the mixture has been neutralised with sodium hydroxide.—W. P. S.

PATENTS.

Gas; [Laboratory] apparatus for the generation of —— formed by the action of liquids on solid reagents. F. Hirsch. E.P. 161,681, 14.1.20.

THE apparatus consists of a reservoir, containing the liquid reagent, connected through a tap with a long tapering generating tower with a perforated bottom constricted to a tube forming a tight connexion with a receiver placed beneath it, into which the spent liquor from the generating tower flows. The receiver is furnished with a gas outlet at the top and a spent liquor outlet at the base. The gas is thereby caused to pass through the mass of the solid reagent in the tower in order to reach the gas outlet, and when the latter and the reservoir tap are closed the further generation of gas ceases.
—G. F. M.

Gas analysing apparatus. Svenska Aktiebolaget Mono. E.P. 138,355, 28.1.20. Conv., 29.1.19.

IN gas analysing apparatus operated as described in E.P. 16,561 of 1908 and provided with two or more measuring vessels, synchronous analyses may be carried out by arranging that the gas from only one of the measuring vessels passes through the remaining members of the apparatus, whilst the gas from the other measuring vessels escapes to the atmosphere.—J. S. G. T.

Analysing gases; Apparatus for ——. R. H. Davis and C. Rosling. E.P. 160,930, 30.12.19.

APPARATUS for analysing gases comprises a vessel containing an absorbent of the constituent to be determined, both ends of the vessel being in the form of diaphragms such as are employed in aneroid barometers. Gas is admitted to the vessel through a valved inlet and the change of pressure due to absorption of a constituent of the gas is transmitted by one of the diaphragms to a pointer moving over a scale. The second diaphragm controls the entry and exit of gas before and after analysis, and serves to retain the absorbent liquid for subsequent analyses.—J. S. G. T.

Gas-analysing apparatus. O. Rohde, and Svenska Aktiebolaget Mono. E.P. 160,854, 7.8.19.

IN apparatus in which two measuring vessels are employed for measuring the volume before and after absorption of various constituents, the first measuring vessel is cooled by liquid flowing into its interior, and the second by liquid flowing in a helical coil surrounding the vessel. The liquid is kept in circulation by means of a pump, and preferably a regulating vessel is inserted in the discharge pipe so that the flow of cooling water may be adjusted to about 3 to 5 drops per sec.—J. S. G. T.

Gas-analysing apparatus. O. Rohde, Assr. to Svenska Aktiebolaget Mono. U.S.P. 1,373,264, 29.3.21. Appl., 8.9.19.

SEE E.P. 160,854 of 1919; preceding.

Gas; Apparatus for analysing ——. O. Rohde, Assr. to Aktiebolaget Ingeniörsfirma F. Egnell. U.S.P. 1,374,391, 12.4.21. Appl., 29.1.17.

SEE E.P. 104,160 of 1916; J., 1918, 447 A.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Caldwell. Crushing and grinding apparatus. 13,272. May 10.

Collins. Furnaces for steam-generators, kilns, etc. 13,842. May 17.

Cross. Compositions for preventing corrosion and removing incrustation in boilers etc. 13,636. May 13.

Ingersoll-Rand Co. Devaporising and cooling. 13,814. May 14. (U.S., 5.6.20.)

Lloyd and Miller. Grinding or crushing machines. 13,564. May 13.

Lodge Fume Co., and others. 14,230-1. *See* XI.

Nitrogen Corp. Catalyst, and method of preparing same. 13,161. May 9. (U.S., 8.5.20.)

Rigby. Heating or cooling liquids or admixed solids in evaporative etc. treatment. 13,206. May 10.

Techno-Chemical Laboratories, Ltd., and Boberg. Refrigeration. 13,253. May 10.

Wade (Union Trust Co.). Regenerative furnaces. 14,152. May 20.

Weddingen. Removing incrustation from boilers and softening feed-water therefor. 14,147. May 20.

COMPLETE SPECIFICATIONS ACCEPTED.

17,331 (1917). Krause. Evaporising or cooling solutions, emulsions, and suspensions, and production of chemical reactions. (162,678.) May 19.

28,244 (1919). Hall. Grinding, crushing, or disintegrating machines. (163,064.) May 25.

29,488 (1919). Cathcart. Method and apparatus for drying. (162,705.) May 19.

31,696 (1919). Soc. l'Air Liquide. Separation of constituents of gaseous mixtures. (136,837.) May 19.

32,639 (1919). Mitchell. Apparatus for making emulsions. (162,719.) May 19.

3212 (1920). Poore. *See* II.

4065 (1920). Engelke. Filtration of liquids. (163,105.) May 25.

4267 (1920). Merz. Receptacles for use in connexion with the crystallisation of solutions. (163,116.) May 25.

4729 (1920). Duparc and Urfer. Production of catalysts. (140,061.) May 25.

7468 (1920). Bonsignori. Evaporator. (162,877.) May 19.

7713 (1920). Vermaes, and Syndicaat Electrostaal. Rotary kilns. (163,175.) May 25.

8485 (1920). Larsen. Burning watery materials in kilns. (144,255.) May 25.

10,947 (1920). Losey. Apparatus for disintegrating fused materials. (162,909.) May 19.

19,579 (1920). Martini u. Hüneke Maschinenbau A.-G. Protecting inflammable liquids from fire. (147,622.) May 19.

20,626 (1920). Danhardt. Metallic filter for separating solids from gases. (148,795.) May 19.

26,941 (1920). Wettig, and Topf u. Söhne. Apparatus for drying granular material. (163,244.) May 25.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Atkinson. Combustion of fuel. 13,323. May 11.

Bergh. Retorts for distilling shale etc. 14,153. May 20.

Boardman, Madden, West, and West's Gas Improvement Co., Ltd. Destructive distillation of coal etc. 13,633. May 13.

Booer. Materials for purifying acetylene. 13,180. May 9.

Dunstan and Thole. Treatment of petroleum etc. 13,174. May 9.

Dunstan. Refining liquid hydrocarbons. 13,515. May 12.

Fournier. Manufacture of artificial fuel. 13,246. May 10. (Fr., 30.7.20.)

Kirke. Water-gas plants. 13,637. May 13.

Kirke. Combustion of fuel. 13,638. May 13.

Meikle. Vertical retort. 13,223. May 10.

Nitrogen Corp. 13,813. *See* VII.

Tarrant, and Tarrant, Ltd. Fuel blocks. 13,416. May 11.

Torfverwertungsges. Treatment of raw peat. 13,277–8. May 10. (Ger., 22.6 and 6.10.20.)

Tulloch. Fuel, and production of gas therefrom. 13,508. May 12.

Complete Specifications Accepted.

20,598 and 25,103 (1919). Low Temperature Carbonisation, Ltd., Davidson, and Armstrong. Distillation of coal etc. (162,684.) May 19.

2057 (1920). Goldschmidt and Migeon. *See* XVIII.

2319 (1920). American Coke and Chemical Co. Regenerative coke-ovens etc. (138,125.) May 19.

3212 (1920). Poore. Apparatus for carbonising sawdust etc. and for treating gases and vapours with finely-divided substances. (162,769.) May 19.

3860 (1920). Firth, Blakeley, Sons and Co., and Blakeley. Gas purifiers. (163,095.) May 25.

5563 (1920). Glover, West, and West's Gas Improvement Co. Vertical retort setting for the destructive distillation of coal etc. (163,150.) May 25.

7180 (1920). Evans. Refining crude oil etc. by distillation. (163,173.) May 25.

7181 (1920). Evans. Crude oil refining processes and apparatus. (162,873.) May 19.

10,835 (1920). British Thomson-Houston Co. *See* X.

13,718 (1920). Sawtelle. Destructive distillation of wood. (143,545.) May 25.

16,539 (1920). Lotz. Burning pulverulent fuels. (162,958.) May 19.

III.—TAR AND TAR PRODUCTS.

Applications.

Adam, Galbraith, Shannon, and Siderfin. Manufacture of amines from phenolic compounds. 13,664. May 13.

Plauson's (Parent Co.), Ltd. (Plauson). 14,188. *See* XX.

Complete Specifications Accepted.

27,221 (1919). Sasa. Manufacture of phthalic anhydride. (140,051.) May 19.

79 (1920). Commin. Treating pitch. (162,727.) May 19.

10,924 (1920). Tindale. Distillation of tars and treatment of residual pitches. (163,199.) May 25.

IV.—COLOURING MATTERS AND DYES.

Applications.

Barritt. Azo dyestuffs and intermediates. 13,764. May 17.

Farbenfabr. vorm. F. Bayer u. Co. Manufacture of copper compounds of substituted azo dyestuffs. 13,624. May 13. (Ger., 14.6.20.)

Johnson (Badische Anilin- u. Soda-Fabr.). 14,161. *See* XIII.

Complete Specification Accepted.

23,799 (1919). Pope, and Scottish Dyes, Ltd. Production of colouring matters. (162,687.) May 19.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Boyer. Treatment of fabrics, paper, etc. 13,509. May 12.

Eyrich and Schreiber. Removing ink from print paper. 13,850. May 17.

Humphrys. Treating flax, straw, etc. 14,175. May 20.

Plauson's (Parent Co.), Ltd. (Plauson). Extraction of wood. 13,758. May 17.

Plauson's (Parent Co.), Ltd. (Plauson). 14,187. *See* XVII.

Schülke. Production of artificial multiple-filament threads from cellulose solution. 13,592. May 13. (Ger., 17.5.20.)

Schülke. Production of wool-like yarns from artificial threads. 14,033. May 19. (Ger., 20.5.20.)

Complete Specifications Accepted.

2120 (1920). Deuts. Celluloid Fabrik. Manufacture of cellulose compounds. (138,116.) May 19.

2995 (1920). Bouillon and Worms. Treatment of cellulose filaments, threads, or films. (162,759.) May 19.

3951 (1920). Courtaulds, Ltd., and Stokes. Washing or otherwise treating with liquids artificial filaments etc. (163,099.) May 25.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Ashworth. Dyeing-apparatus. 14,002. May 19.

Brandwood and Brandwood. Bleaching, dyeing, etc. yarns wound in cheese form. 13,571. May 13.

Britton and others. 13,871. *See* XIV.

Complete Specifications Accepted.

32,733 (1919). Kershaw and Cole. Machines for dyeing, mordanting, bleaching, etc. wool, slubbing, yarn, etc. (162,720.) May 19.

3537 (1920). Arent. Fireproofing and/or waterproofing treatment of materials. (138,641.) May 19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Crosland. 13,676. *See* IX.

Gaillard. Manufacture of sulphuric acid. 13,210. May 10.

Harter and Oehlrich. Production of a contact mass for the catalytic synthesis of ammonia. 13,656. May 13.

Minami Manshu Tetsudo Kabushiki Kaisha. Manufacture of anhydrous chlorides of alkaline-earth metals. 13,290. May 10. (Japan, 15.5.20.)

Nitrogen Corp. 13,161. *See* I.

Nitrogen Corp. Preparation of gas mixtures and ammonia. 13,162. May 9. (U.S., 8.5.20.)

Nitrogen Corp. Production of hydrogen and ammonia. 13,812. May 17. (U.S., 14.5.20.)

Nitrogen Corp. Production of hydrogen from hydrocarbons. 13,813. May 17. (U.S., 25.5.20.)

Soc. Anon. de Prod. Chimiques Etabl. Malétra. Continuous production of sulphates. 14,035. May 19. (Fr., 25.5.20.)

Wilton and Wilton. Manufacture of sulphate of ammonia. 13,261. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

2838 (1920). Edwards. Manufacture of arsenical compounds. (162,747.) May 19.

6206 (1920). Ellis (Foundation Oven Corp.). Purification of ammonium salts. (163,162.) May 25.

13,579 (1920). McKee. Manufacture of hydrogen and zinc oxide. (163,210.) May 25.

17,453 (1920). Röhm. Production of a solid non-hygroscopic iron salt. (146,216.) May 19.

18,165 (1920). Collin A.-G. Discharging ammonium sulphate from saturator baths. (145,781.) May 19.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Clark. Moulding and annealing glass. 13,346. May 11. (U.S., 11.5.20.)

Feldenheimer and Plowman. Treatment of clay. 13,172. May 9.

Plauson's (Parent Co.), Ltd. (Plauson). Refining china clay etc. 14,189. May 21.

Wolf. Cementing procelain. 13,413. May 11.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Crosland. Kilns for calcining lime, cement, plaster, ores, etc. 13,676. May 13.

Hildyard. Production of imitation wood. 13,504. May 12.

Rowse. Manufacture of roofing and building materials. 14,234. May 21.

Whitby. Imparting a highly-glazed surface to artificial stone. 13,251. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

20,130 (1919). Crawford. Manufacture of bricks. (162,683.) May 19.

34,876 (1920). Alletson. Kilns for burning blue or other bricks. (163,251.) May 25.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Ashcroft and Lacell. Treatment of ores etc. 13,605-6. May 13.

Ashcroft and Lacell. Production and purification of lead. 13,607. May 13.

Booer, and District Chemical Co. Flux for welding or depositing metals electrically. 13,181. May 9.

Brunskill. Treatment to obviate rusting or oxidation of iron or steel surfaces. 13,235. May 10.

Crosland. 13,676. *See* IX.

James, and Star Electric Accessories, Ltd. Casting metals of high melting-point. 13,783. May 17.

Jones. Coating metal plates. 13,268. May 10.

Marino. Removing rust, grease, paint, etc. from iron and steel. 14,164. May 20.

Minerals Separation, Ltd., and Vautin. Treatment of ores. 13,283. May 10.

Smaill. Production of an alloy. 13,158. May 9.

Soc. d'Electro-Chimie et d'Electro-Métallurgie. Obtaining deposits of iron by electrolysis. 13,621. May 13. (Fr., 9.6.20.)

Soc. d'Electro-Chimie et d'Electro-Métallurgie. Obtaining metallic electrolytic deposits easily detachable from the cathode. 13,622. May 13. (Fr., 13.6.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

19,028 (1919). Browning. Extraction of metals from solutions or separation of metals. (162,682.) May 19.

25,116 (1919). Lane and Williams. *See* XII.

32,571 (1919). Storen and Johanson. Treatment of poor iron ores containing weakly magnetic or non-magnetic oxygen compounds of iron. (162,718.) May 19.

22 (1920). Wright. Smelting or reduction of iron ore. (162,725.) May 19.

3181 (1920). Eklund. Recovery of tin from stanniferous waste products. (138,622.) May 19.

3594 (1920). Heraeus Ges. Vacuum melting and refining of metals and alloys. (138,648.) May 19.

3672 (1920). Lang. Furnace for making iron and steel. (162,808.) May 19.

3731 (1920). Heraeus Ges. Purifying and refining iron. (138,651.) May 19.

4064 (1920). McCaffery. Bessemerising iron. (138,900.) May 19.

4100 (1920). Jackson (Forge Products Corp.). High-speed steel and process of forming and forging the same. (163,100.) May 25.

10,835 (1920). British Thomson-Houston Co. (General Electric Co.). Tungsten alloys especially for electric lamp filaments. (162,907.) May 19.

11,934 (1920). Electrolytic Zinc Co. of Australasia. Recovery of zinc by electrolysis. (155,792.) May 25.

12,432 (1920). Vos. Alloys. (162,917.) May 19.

13,831 (1920). Krupp A.-G. Manufacture of hard cast-iron articles. (143,554.) May 25.

15,645 (1920). Heraeus Ges. Treating metal used in the manufacture of parts of vacuum tubes. (144,690.) May 25.

26,768 (1920). Kilby and Bacon. Recarburising molten steel in an open-haarth furnace. (162,994.) May 19.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Booer and others. 13,181. *See* X.

Burgess Battery Co. Dry cell. 13,661-2. May 13. (U.S., 15.5.20.)

Coley and Frampton. Regeneration of spent dry cells. 14,149. May 20.

Garbutt. Electric accumulators. 13,398-9. May 11.

Hancock and Hancock. Electric furnaces. 13,497. May 12.

Lodge Fume Co., Ltd., Lodge, and Stallard. Electrical precipitation apparatus. 14,230-1. May 21.

Niblett. Apparatus for producing electrolytic compounds. 13,192. May 10.

Niblett. Primary and secondary batteries. 13,681. May 17.

Soc. d'Electro-Chimie et d'Electro-Métallurgie. 13,621-2. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

11,934 (1920). Electrolytic Zinc Co. *See* X.

13,671 1920. Merrmann. Manufacture of material for use as electrical insulator. (153,884.) May 19.

XII.—FATS; OILS; WAXES.

APPLICATION.

Pineger. Detergent. 13,114. May 9.

COMPLETE SPECIFICATIONS ACCEPTED.

25,116 (1919). Lane and Williams. Treatment of waste grease from tin works and other works. (163,056.) May 25.

25,355 (1919). Williams and Moseley. Soaps, polishes, etc. (162,691.) May 19.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Anderson and Maclaurin. Preparation of synthetic resins. 13,744. May 17.
Ivinson and Roberts. Enamel or varnish. 13,912. May 18.
Johnson (Badische Anilin u. Soda-Fabrik). Production of pigment colours. 14,161. May 20.
Lefebvre. Obtaining an oil having the chemical properties of oil of turpentine. 13,160. May 9.

COMPLETE SPECIFICATION ACCEPTED.

18,900 (1920). Jerone. Waterproof paints. (146,986.) May 19.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Britton, and Griffiths Bros. and Co. Preparation of rubberised fabrics and rubber goods. 13,871. May 17.

COMPLETE SPECIFICATIONS ACCEPTED.

16,560 (1920). Farrell Foundry and Machine Co. Mixing or masticating rubber etc. (147,547.) May 25.
18,915 (1920). Goodyear Tire and Rubber Co. Manufacture of rubber products. (146,992.) May 19.
19,585 (1920). Waitz. Recovering caoutchouc and fabric from rubbered fabric. (147,628.) May 25.

XV.—LEATHER; BONE; HORN; GLUE.

COMPLETE SPECIFICATIONS ACCEPTED.

63 (1920). Melamid. Manufacture of artificial tanning substances. (137,323.) May 19.
4080 (1920). Marks (Chicago Process Co.). Liming and dehairing hides. (163,109.) May 25.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATION ACCEPTED.

5100 (1920). Silberrad. Artificial manures. (163,137.) May 25.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Plauson's (Parent Co.), Ltd. (Plauson). Saccharification of wood and like cellulosic materials. 14,187. May 21.

COMPLETE SPECIFICATION ACCEPTED.

19,707 (1920). Aumann. Preparation of sugar beets suitable for making marmalades, extracts, wines, beers, etc. (147,713.) May 19.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Bryant. Aeration of brewers' wort etc. 13,924. May 18.

COMPLETE SPECIFICATIONS ACCEPTED.

2057 (1920). Goldschmid and Migeon. Treatment of peat, distillers' wash, etc. (162,738.) May 19.
19,707 (1920). Aumann. *See* XVII.
22,102 (1920). Bensley. Portable dry yeast. (162,978.) May 19.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Baker, and Fluorescent Materials, Ltd. Charging water etc. with radium emanation. 13,873. May 17.
Pennell. Filtration of turbid water etc. 13,411. May 11.
Prentice and Stevenson. Sterilisation of milk etc. 13,537. May 13.
Weddingen. 14,147. *See* I.

COMPLETE SPECIFICATIONS ACCEPTED.

2972 (1920). Koppers Co. Purification of liquids. (139,159.) May 25.
8229 and 8330 (1920). Wood. Food compositions. (140,462–3.) May 19.
19,707 (1920). Aumann. *See* XVII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Chem. Fabr. vorm. Sandoz. Manufacture of a new preparation of hexamethylenetetramine. 13,981. May 18. (Switz., 12.6.20.)
Dreyfus. Manufacture of organic products. 13,472. May 12.
Hoffmann-La Roche u. Co. Manufacture of soluble double compounds of 1-allyl-3.7-dimethylxanthine. 13,674. May 13. (Switz., 2.7.20.)
Hoffmann-La Roche u. Co. Manufacture of 1-allyl-3.7-dimethylxanthine. 13,675. May 13. (Switz., 2.7.20.)
Lefebvre. 13,160. *See* XIII.
Mills. Blood coagulation mediums. 13,276. May 10. (U.S., 6.5.20.)
Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of ichthyol oil and ichthyol preparations etc. 14,188. May 21.
Soc. Anon. de Prod. Chim. Etabl. Malétra. Production of acetaldehyde from acetylene. 14,049. May 19. (Fr., 15.6.20.)
Soc. Chim. des Usines du Rhône. Compressed vanillin. 14,244. May 21. (Fr., 17.2.21.)

COMPLETE SPECIFICATIONS ACCEPTED.

16,211 (1920). Badische Anilin- u. Soda-Fabrik. Manufacture of urea. (145,060.) May 25.
31,000 (1920). Penfold. Manufacture of serum from animals. (154,886.) May 25.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Camiller and Hay. Manufacture of multicolour screens, films, etc. for natural colour kinematography etc. 13,637. May 13.
Christensen. Multicolour screens for photography. 13,524. May 12. (Denmark, 15.5.20.)
Lage. Production of coloured photographs. 14,031. May 19.

XXII.—EXPLOSIVES; MATCHES.

COMPLETE SPECIFICATION ACCEPTED.

27,032 (1919). Brock and Butt. Pyrotechnics, matches, percussion caps, fuses, etc. (162,697.) May 19.

XXIII.—ANALYSIS.

APPLICATION.

Dale. Apparatus for analysis and recording of gases. 13,447. May 12.

COMPLETE SPECIFICATIONS ACCEPTED.

4228 (1920). Fairweather. Gas calorimeters. (162,826.) May 19.
20,902 (1920). Arndt. Gas-analysing apparatus. (148,998.) May 19.

I.—GENERAL; PLANT; MACHINERY.

Protective linings and coverings for chemical plant. F. Schüler. Chem.-Zeit., 1921, 45, 315—316.

Most of the coverings in use for protecting chemical plant present some disadvantages, and some have a very limited application. Metallic coatings applied galvanically have a short life owing to their thinness and porosity. Sheet metal linings cannot be used with vacuum plant, as the air between them and the walls of the vessel tends to loosen them; on the other hand, a homogeneous layer of lead is satisfactory in many cases. Coating vessels with paints or varnishes is not successful when these are subject to mechanical friction from stirrers etc. or to raised temperature. Enamelled apparatus has frequently considerable durability, but its liability to chip is a drawback. Earthenware linings have found an extensive use, especially with acids, and the sections are sometimes applied in double layers, or after previous coating with lead; objections to the use of this material are its thickness, which materially reduces the capacity of vessels, and the fact that it cannot be used for lining tank covers, or for such purposes as in heating coils, where it is liable to fracture. Thin glass plates have been found to be very resistant and in many ways superior to earthenware, inasmuch as they may be used for covering parts of apparatus and also for lining jacketed vessels, for which earthenware is unsuitable owing to its thickness. Glass linings are not liable to fracture by sudden changes of temperature.—W. J. W.

Humidity control by means of sulphuric acid solutions, with critical compilation of vapour pressure data. R. E. Wilson. J. Ind. Eng. Chem., 1921, 13, 326—331.

The use of sulphuric acid solutions of definite composition affords the most convenient means of obtaining atmospheres of known humidity; the air is bubbled through three successive vessels containing sulphuric acid of the necessary strength. The acid in the first vessel usually needs changing when its volume has altered by 3—4%. A graph is given showing the strength and gravity of sulphuric acid solutions which will give any desired humidity to air; for instance, reference to the graph shows that a relative humidity of 50% at 25° C. is obtained with 43·4% sulphuric acid (sp. gr. at 25° C., 1·329). Formulæ are also given for calculating the vapour pressures from one temperature to another when it is desired to employ other temperatures than those shown on the graph.—W. P. S.

Patents.

Cooling viscous liquids; Process for —— and apparatus therefor. Soc. des Condenseurs Delas. E.P. 142,454, 19.4.20. Conv., 30.4.19.

The viscous liquid (*e.g.* heavy oil) flows in the form of threads through suitable nozzles on to a vertical series of water-cooled pipes, the oil spreading over the whole surface of the pipes but re-forming into drops or threads upon the underside and dropping upon the next pipe. In order to ensure that there shall be no mixing of the liquid and the cooling water as a result of leakage, the header plates supporting the tubes at each end may be double, with a space between.—B. M. V.

Electrical gas purification. Metallbank u. Metallurgische Ges. A.-G., and J. E. Lilienfeld. E.P. 145,477, 21.6.20. Conv., 8.8.18.

The generation of ions in the electrical discharge is increased by the use of pulsating undamped direct current voltage, the frequency of pulsation ranging from 250 to 1500 cycles per sec., and the number of cycles being adapted to the capacity of the high tension circuit, so that the pulsations are not smoothed out by the capacity of the circuit. The pulsating direct current voltage is suitably obtained by superimposing upon a constant direct current voltage an oscillation of a considerably greater frequency than that of the usual technical alternating current.—J. S. G. T.

Disintegrators or pulverisers. J. Bray. E.P. 148,551, 10.7.20. Appl., 28.2.19.

In a Carr's disintegrator, to prevent accumulation of partly ground material in the fine grinding chamber, the faces of the outermost ring of percussion members are inclined to throw the material inwards, the faces of the next ring of percussion members being oppositely inclined. In addition to the screens in the grinding track others may be arranged at the side thereof and a current of air used to draw out the finely ground material.
—B. M. V.

Centrifugal machines. P. T. Sharples. E.P. 148,753, 3.7.20. Conv., 30.7.19.

The material is fed to, and solids discharged from, the bowl through an axial hole in a boss at the bottom. The boss and the bowl are steadied by a drag-bearing permitting slight radial movement and contained in a conical plug easily removable from the outer casing of the machine. The plug also contains means for lubrication of the bearing and a nozzle for introducing the material upwards through the bottom.—B. M. V.

Centrifugal separator. E. D. Gray, Assr. to Standard Oil Co. of California. U.S.P. 1,375,506, 19.4.21. Appl., 2.9.20.

The top of the bowl, forming a closed chamber, is provided with a peripheral pocket. An axial inlet pipe enters near the bottom of the chamber, and a substantially axial outlet pipe leads from a point above the pocket. An outlet from the top of the bowl near its outer edge leads to a chamber forming a casing around the bowl.—H. H.

Acid-gas or similar substance mains; Pipe connections for ——. P. L. Pfannenschmidt. E.P. 149,684, 31.7.20. Conv., 31.7.19.

To avoid destruction of the jointing-material of horizontal mains by condensed acid, one pipe end extends beyond the jointing material into an enlarged part of the other pipe from which the condensed acid may be removed. Two similar pipe ends may be symmetrically fitted within a connecting piece jointed to each and formed with an enlargment for collecting the condensed acid.
—H. H.

Filters. J. Miller, and G. Fletcher and Co., Ltd. E.P. 161,993, 5.5.19.

A filter as described in E.P. 158,387 (J., 1921, 203 A) is provided with a stop-cock at the bottom to remove sediment while the filter is in operation and with another cock, preferably leading to the outlet trunnion, through which the residual filtered liquor in the filter can be removed before opening the filter to change the filtering medium. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 23,585 of 1895.)—B. M. V.

Filters; Production of very fine [ultra-] ——. E. de Haën, Chem. Fabr. "List," G.m.b.H. G.P. 334,063, 27.1.20.

In the preparation of ultra-filters by deposition from a colloidal solution upon a supporting layer,

which may contain a coagulating agent, the colloidal solution (collodion) is treated with a coagulating agent (water) before it is poured on the supporting layer (filter paper). The permeability of the filter will vary according to the amount of water added and according to the vapour pressure of the water; addition of hygroscopic substances such as calcium chloride or glycerin has a favourable influence on the quality of these ultra-filters.—J. H. L.

Filter pulp; Process and apparatus for washing ——. E. Steuer. G.P. 334,113, 17.6.19.

The pulp is subjected to the action of water which has been charged under pressure with air or gas. The gas in escaping from solution, loosens the fibres and carries them to the surface. The "gas emulsion" may be produced chemically, *e.g.*, by the action of acids on suitable substances below, in, or above the filter pulp. The apparatus comprises a vessel provided with a perforated false bottom and divided ducts below the latter connected with a pressure vessel in which the washing liquid is saturated with air or gas.—J. H. L.

Stills [; Entrainment separator for ——]. A. Philip. E.P. 162,000, 15.9.19 and 29.1.20.

A separator for entrained liquid consists of a number of frusto-conical plates placed close together, with their small ends downwards, in the vapour space of a still, so that any entrained liquid will be caught on the surface of the plates and run back into the distilling liquid. The separator is provided with a conical or domed roof so that any liquid which condenses after passing the separator will be led to a gutter and thence outside the still. The device is specially suitable for mineral oil stills.—B. M. V.

Liquids and gases; Apparatus for bringing —— *into intimate contact.* W. C. Holmes and Co., Ltd., D. M. Henshaw, and J. Whittell. E.P. 162,166, 1.4.20.

In a scrubber consisting of a number of brush rings secured back to back in pairs to a series of discs rotating between other fixed discs and dipping into the washing liquid, the rotating discs are perforated between the brush rings and the shaft, and passages are formed through the fixed discs alternately within and without the brush rings. The gas current splits into two streams which pass through the brushes of each pair in the same direction and through adjacent pairs in opposite directions.
—B. M. V.

Separating floating and other impurities in suspension from liquids; Apparatus for ——. C. G. Petree. E.P. 162,206, 4.6.20.

The liquid to be treated, *e.g.*, defecated sugar juice, is delivered tangentially upon a gallery surrounding a central circular hole in the cover of a conical settling vessel and flows through the hole into a cylinder extending from the cover beneath the surface of the liquid in the vessel. This cylinder is provided with an opening near its upper end for the escape of liquid, which is thereupon directed by a volute wall along a path of considerable length to a scum deflector and an overflow for the clear liquid. The scum is intercepted by a plate extending above and below the surface of the liquid and is directed by mechanically-actuated blades to an outlet.—H. H.

Drying finely divided materials. H. F. Chappell U.S.P. 1,375,080, 19.4.21. Appl., 14.11.18.

The material to be dried is fed on to one end of a travelling platform which is enclosed in an outer chamber. Heating gases which pass through a flue under the platform provide the necessary heat for the drying operation.—G. A. K.

Dryer. E. B. Ayres, Assr. to Proctor and Schwartz, Inc. U.S.P. 1,376,244, 26.4.21. Appl., 27.5.20.

A casing is divided into a heating and two drying compartments, and a fan situated in one of the latter circulates air through all three compartments.—B. M. V.

Drying kiln. S. E. Cornish, Assr. to H. H. Plummer. U.S.P. 1,376,319, 26.4.21. Appl., 20.1.20.

A kiln is provided at one side with fans which direct air through flues to points on the opposite side of the kiln intermediate between the inlets to the fans, so as to create a continuous circuitous movement of air in the kiln.—B. M. V.

Dryer; Column —— *consisting of separate cells.* G. Zimmermann. G.P. 333,943, 5.7.17.

In a column dryer consisting of a number of cells each of which is connected with the one below it by a funnel-shaped constriction, the walls of the cells are provided with oblique openings for the current of air which traverses the cells. The descending material travels only very slowly in the cells themselves, and owing to the wide openings in their walls the transverse air currents have a relatively small velocity and encounter only small resistance.—J. H. L.

Fire-extinguishing composition. P. A. Crosby, R. R. Matthews, and R. B. High, Assrs. to Roxana Petroleum Co. U.S.P. 1,375,779, 26.4.21. Appl., 8.8.19.

The constituents of the composition are sodium bicarbonate, a phosphoprotein, and water.
—B. M. V.

Catalytic material [nickel]; Process of making ——. S. Drucker, and W. Sieck, jun. U.S.P. 1,375,368, 19.4.21. Appl., 7.11.19.

Nickel carbonate is precipitated from a nickel salt solution, washed, mixed with a powdered inert non-reducible material, and the mixture dried without calcining and reduced in an atmosphere of hydrogen.—H. H.

Alcohol and ether [vapours] from admixture with air; Process for the recovery of ——. E. Bindschedler. U.S.P. 1,376,069, 26.4.21. Appl., 2.8.20.

Alcohol is removed from the mixed vapours by intimate contact with water, and ether absorbed from the residue by means of concentrated sulphuric acid.—J. S. G. T.

Tube evaporator; Rotary ——. A.-G. der Chemischen Produkten-Fabrik Pommerensdorf. G.P. 333,304, 22.12.17.

To avoid vibration, and failure of the driving gear, a tube evaporator is placed eccentrically in its fire chamber, and is so arranged that its weight is equally distributed on both sides of the drive.
—W. J. W.

Separation of small quantities of materials from liquids and gases. H. Bechhold. G.P. 335,303 31.8.18.

Solid impurities are removed from a liquid or gas by adsorption on a suitable medium, such as charcoal or fuller's earth, provided with a coating of insoluble material which enters into combination with the impurities to be removed. For example air is freed from chlorine by filtration through charcoal coated with 2% of mercury.—C. I.

Gas-mixtures; Separation of —— *by means of a internally heated column.* G. Petzel. G.P. 335,115, 10.4.14.

The column is fitted with an internal heating coi

The highly compressed gas mixture, *e.g.*, air, before entering the coil, is allowed to expand to the pressure suitable for operating the column, the cold produced by the expansion serving to cover the losses through radiation etc.—C. I.

Pulveriser mills. Fuller-Lehigh Co., Assees. of J. W. Fuller. E.P. 145,497, 21.6.20. Conv., 1.6.18.

See U.S.P. 1,345,082 of 1920; J., 1920, 564 a.

Separation of gas mixtures; Process for the ——. G. Petzel. E.P. 148,302, 9.7.20. Conv., 9.4.14.

See G.P. 335,115 of 1914; preceding.

Separating suspended matter from liquids; Process and apparatus for ——. A. F. Meston. E.P. 162,390, 28.1.20.

See U.S.P. 1,334,160 of 1920; J., 1920, 355 a.

Grinding-mills [; Open-pan ——] for grinding flint, china stone, and other materials. W. F. Malkin. E.P. 162,481, 8.3.20.

Protecting walls of reaction vessels. E.P. 140,083. *See* VII.

Removing dust from gases. E.P. 147,020. *See* X.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

'omplete gasification; Experiments in ——. F. H. Robinson. N. Eng. Gas Managers' Assoc., 6.5.21. Gas World, 1921, 74, 368—371.

:xperiments were carried out at Harrogate on a attery of eight retorts, 14 ft. long by 22 in. by 6 in., with a water-gas generator at one end, the hole installation being accommodated within the rch of the retort-bench. The ends of the retorts n the charging side had the ascension pipes con- ected in the usual way, whilst the other ends erminated in a chamber above the generator. 'rimary and secondary air could be admitted or hut off simultaneously by means of a piston valve hich was also connected with the steam jet, the team supply to the blowing engine, and the stack alve, so that only one movement was necessary to hange from "blow" to "run," or *vice versâ*.)uring the run, the water-gas passed from the enerator into and through the retorts and away o the ascension pipes, the heat of the hot gas being hus utilised. The coke was discharged from the 'arious retorts in turn to the generator. A thin ar, sp. gr. 1·12, was obtained, which yielded water ·2%, light oils to 170° C. 1·6%, 170°—230° 3·4%, 30°—270° 13·8%, 270°—300° C. 7·2%, and pitch 8·8%. It was entirely free from separated aphthalene even on standing overnight. The oal used was a mixture of Yorkshire and Durham ontaining 2·87% of moisture, and (on a moisture- 'ree basis) 29·50% of volatile matter, 57·00% of ixed carbon, and 13·50% of ash. The setting was onnected with the foul mains in the retort house o that the hot water-gas could be enriched with he lighter hydrocarbons from the tar vapour herein. The gas produced contained, in one case, CO_2 8·4%, O_2 0·2%, illuminants 1·4%, CO 18·9%, CH_4 17·42%; H_2 39·26%, and N_2 14·42%, and had a alorific value of 396 B.Th.U. per cub. ft. (gross). The average CO content over a long period was 9·3%, whilst the CO_2 content was 5·8% and the alorific value was 384 B.Th.U. per cub ft. The total efficiency of the process as determined on three occasions was 70·3%, 73·3%, and 82·6% respectively, values which are very close to the figures mentioned in the Clerk-Smithells-Cobb report of 1919.—A. G.

Producers for the gasification of natural fuels with recovery of the by-products. H. Koshmieder. Brennstoff-Chem., 1921, 2, 134—135, 150—152.

Three separate zones may be distinguished in a producer using natural fuels such as wood and peat, viz., the upper zone in which moisture is driven off, the middle zone in which the fuel is destructively distilled, and the lowest zone where the coke is burned. The capacity and height of the producer for most efficient working depend upon the nature of the fuel, and the rate at which it passes through the producer. The variations in the size of the producer required with wood, peat, lignite, and coal are discussed with a view of showing the most efficient dimensions for each type of fuel. The advantages of carbonisation are also discussed for certain fuels. —W. P.

Gas purification. W. A. Dunkley and C. E. Barnes. Gas J., 1921, 154, 27—29, 148—150, 204—205, 266—268, 381—382.

In a co-operative research carried out by the Illinois State Geological Survey Division, the Engineering Experiment Station of the University of Illinois, and the U.S. Bureau of Mines, sixteen gas plants, comprising nearly all the medium-sized plants of the State, including the suburban plants at Chicago, were inspected. Low-sulphur Eastern gas coals were being used in practically all the coal gas plants inspected. The average H_2S content of the gas entering the purifiers was 250 grains per 100 cub. ft. Six of the eight straight water-gas plants were using low-sulphur coals for generator fuel. The average H_2S content in the unpurified gas in these plants was 140 grains per 100 cub. ft. Tar was found in appreciable amounts in the gas entering the purifiers in nearly all the plants inspected, and the spent oxide from all the plants contained some tar (6·9% in that from water-gas plants and 3·6% in that from mixed gas plants). Tar seemed in some cases to be responsible for low sulphur absorption. The spent oxides from mixed gas plants contained, on the average, 37·4% of sulphur, whilst those from straight water-gas plants contained 21·7%. Revivification *in situ* was practised by most water-gas plants, but by few mixed gas plants, and only one plant revivified in the off box. Little trouble was reported in this plant, and the operating cost was low. Though several purifying installations are arranged for reversible gas flow, or for rotation of boxes, little effort seems to be made to realise the fullest advantage of such arrangements. In very few cases were records kept of the performance of particular batches of oxide, and there was a lack of systematic testing of the purifiers to determine the performance of a batch of oxide. Total purification costs for 1919 varied from 0·5 c. to 2·25 c. per 1000 cub. ft. of gas purified. The authors recommend the establishment of simple but regular testing routine, together with better purification records, and the analysis of fouled oxides for sulphur and tar. In several cases coals of higher sulphur content could be used if existing equipment were rearranged and made more flexible in operation.—A. G.

Benzene hydrocarbons; Determination of —— *in coal gas and coke-oven gas.* A. Krieger. Z. angew. Chem., 1921, 34, 192.

The paraffin method for the absorption of benzene hydrocarbons still remains the best practical method for their determination in coal gas etc., and the bad results recorded by Berl and others (J., 1921, 289a) are due to incorrect methods of working, particularly the use of an insufficient amount of absorbent paraffin. Further improvements in this method are attained by removing the last traces of water from the gas by means of carbide, and by using a freezing mixture instead

of ice. The new method using activated carbon offers no advantage over the paraffin method either in point of accuracy or time required.—G. F. M.

Petroleum; Determination of chlorides in ——. R. R. Matthews. J. Ind. Eng. Chem., 1921, 13, 325—326.

FIVE hundred c.c. of the oil is mixed in a cylinder with 125 c.c. of acetone, 1375 c.c. of water is added, and the mixture shaken carefully to avoid the formation of an emulsion. When the water-acetone layer has separated, about 400 c.c. is drawn off, filtered, and the chloride titrated with $N/20$ silver nitrate solution.—W. P. S.

Paraffin; New developments in the separation of —— from lignite tar and its distillates. F. Seidenschnur. Brennstoff-Chem., 1921, 2, 49—51, 73—76, 81—86.

THE method in general use at present consists in distilling the tar with the use of steam or vacuum and chilling the dried distillate oils. The wax that crystallises is removed by filter-pressing and submitted to a process of "sweating." A final treatment with sulphuric acid and decolorising earth may be employed. The process is very expensive in labour and materials. So far the principal objects of the industry have been the production of wax, the expressed oil being used as fuel, but recently this oil has served as a source of lubricating oil, large amounts having been used during the war. One method that has been suggested for separating the wax consists in boiling the distillate oils with alcohol, the wax being preferentially soluble and crystallising from the alcoholic solution on cooling. The separation is, however, very imperfect, the wax containing much oily matter. A number of patents have been taken out for the application of the Edeleanu method, since liquid sulphur dioxide is a fairly good solvent for unsaturated and aromatic compounds, the paraffinoid components remaining undissolved. By the addition of aqueous pyridine or pyridine bases to lignite tar the paraffin is first precipitated, and subsequently other oils, the tar acids remaining dissolved in the aqueous pyridine, and being finally recovered by distillation. Erdmann has found that the addition of two volumes of acetone in conjunction with moderate chilling precipitates the paraffin almost completely. In all these cases the neutral oils, freed from paraffin, may be used as lubricating oils. The author has found that certain mixtures of alcohol and benzol are quite as effective as acetone in precipitating the wax, hard and soft paraffin being capable of preparation in one operation; the mixture is, moreover, sufficiently non-volatile to obviate the losses involved with acetone. A number of experiments at 0° and —20° C. with acetone and with alcohol-benzol show the solubility of paraffin wax in these liquids and the quality of the wax precipitated by them. The apparatus and method of procedure adopted for working up considerable quantities of lignite tars into wax and lubricating oils are described.—A. E. D.

Vaseline and paraffin; Action of oxidising agents on ——. A. Langer. Chem.-Zeit., 1921, 45, 466.

INVESTIGATIONS in regard to the conversion of hydrocarbons into fatty acids were made with vaseline oil, vaseline, and liquid and solid paraffin, using oxidising agents such as potassium permanganate in acid and alkaline solution, sodium hypochlorite and permanganate, manganese dioxide and hydrochloric acid, and nitric acid. When a mixture of yellow vaseline oil and concentrated sodium hydroxide solution was treated for a few days with permanganate, a supernatant oil was obtained and a residue which was dissolved in dilute sulphuric acid. The oil from this residue was only slightly soluble in sodium carbonate or hydroxide solution; when heated with concentrated sulphuric acid, it gave a black crystalline mass and evolved sulphur dioxide. It was insoluble in most solvents. Oxidation with permanganate and sodium hypochlorite solution gave no better results. Liquid paraffin behaved in a similar manner to vaseline oil, when treated with alkaline permanganate. When oxidised with acid permanganate solution, undissolved manganese hydroxide remained; the residue after filtration was dissolved in hydrochloric acid and yielded a soft resin. The oxidation product from solid paraffin is of the nature of a salve; with litharge it forms a lead salt which is soluble in ether. From vaseline a hard and a soft resin are produced, the latter containing no substances of an acid character; the yield of saponifiable matter is smaller than with vaseline oil, nor does the product form soluble lead salts as is the case with the product from solid paraffin.—W. J. W.

PATENTS.

Fuel and method of producing same. L. W. Bates. U.S.P. 1,375,811, 26.4.21. Appl., 22.1.20.

ASPHALT and free-carbon particles in a liquid hydrocarbon are stabilised by mixing "coal distillate or an equivalent peptising substance" with the hydrocarbon and "blending the components and simultaneously peptising the particles with heat treatment between normal temperature and 95° C."
—L. A. C.

Peat and similar material; Manufacture of briquettes from ——. S. Henlein and A. Hopf. G.P. 332,890, 27.11.19.

THE material is first passed through an extrusion press to ensure mixing of its various layers, and is then subjected to a high pressure to remove mechanically combined water, after which it is ground and passed through a rolling mill at a temperature of 200°C., by which means the moisture is reduced to a small percentage. The pasty material obtained may be again pulverised or briquetted without further treatment.—W. J. W.

Pulverulent fuels; Method of and means for burning ——. R. S. Walker. E.P. 139,158, 28.1.20. Conv., 15.2.19.

THE powdered fuel is fed into the combustion chamber in a thin vertical stream of curtain-like formation, and its combustion occurs as a reverting flame from which the ignition of the entering fuel is maintained. The supply of air for combustion is directed into the chamber from below, so that ash, in falling from the combustion zone, is cooled and slagging is thus avoided. The feed device for the fuel consists of a nozzle with a horizontal slot extending transversely across the chamber.—A. G.

Coking plants. Gewerkschaft Emscher-Lippe, and H. Heyn. E.P. 153,313, 2.11.20. Conv., 3.11.19.

THE glowing coke is cooled by the circulation of inert gases through the mass, the gases imparting their heat to a heat-interchange system, *e.g.*, a steam boiler and feed water heater. For example, the coke is loaded into travelling cars which are connected with a blowing system by means of which flue gas is blown through the hot coke, and the hot gases are then passed through two feed water heaters and a steam boiler, travelling on a car which is capable of running along the discharge side of the coking plant.—A. G.

Coke ovens. J. Marr, and The Coke Oven Construction Co., Ltd. E.P. (A) 162,045 and (B) 162,236, 16.1.20.

(A) IN a coke oven of the type having two parallel, horizontal heating flues side by side in each dividing wall between the retorts, an inlet conduit for hot air is provided at the front end of one such flue. A

gas inlet is connected with the conduit, and horizontal ports lead from the other end of that flue to the other flue in the same dividing wall, a second gas supply being connected with the ports, whilst a conduit at the front end of the second flue leads to a discharge conduit for the products of combustion. The flues have longitudinal horizontal partitions extending from the conduit at the front right to the back of each flue. Ports at the rear ends of the flues afford communication from each of the spaces between the partitions in one flue to the spaces at the same level in the return flue. Each space has a gas inlet at the rear end of the flue. Either of the two conduits at the front ends of the two flues acts as the inlet, as desired, and both the conduits are provided with gas inlets. The conduits at the front ends of the two flues, one on each side of each retort, are connected with a single sole channel running longitudinally below the retort for its whole length, with or without a preliminary gas admission at the rear end of the sole channel. (B) The retorts have horizontal heating flues in the walls and regenerators below the retorts, each communicating with the adjacent ends of two flues, the next adjacent regenerator on each side communicating with the other end of one of the abovementioned two flues and also with the adjacent end of the next flue. Alternate regenerators are employed for the supply of the air and for the exhaust of the waste gases, two transverse main flues communicating one with one set of alternate regenerator chambers and the other with the other set. Means are provided for establishing communication between either main flue and either the chimney or the atmosphere, so that the flow of the heated gases through the flues may be reversed. Recuperator passages are provided in which partially cooled burnt gases issuing from the regenerators are utilised for preheating the combustible gas by conduction of heat through the walls. One or more additional compound flues are provided with passages for the gas to be heated and for the hot burnt products, conduits affording communication between the passages for burnt products at one end of the said compound flue and the chimney and between the other end of the compound flue and the main transverse flues. In the compound flue, passages for gases extend longitudinally through the flue and are built up of blocks, each containing one or more vertical ports which extend transversely to the direction of the passages and baffles to direct the gases passing through the ports to and fro across the longitudinal passages.—A. G.

*Gas-producer.** G. E. and G. M. Williams. E.P. 162,455, 21.2.20.

AIR and steam are introduced as a circular blow through an annular hollow chamber, surmounted and overhung by an annular water-cooled casing. This directs the blast into the centre of the producer, and the cooling prevents clinker adhering. —C. I.

Solid and gaseous fuel; Process and plant for the continuous production of —— with by-product recovery. H. Nielsen and J. R. Garrow. E.P. 162,459, 23.2.20.

ONE of a battery of gas producers is supplied with just sufficient fuel to produce such a quantity of gas that the sensible heat of the gas is sufficient to carbonise the charge in a retort at a low temperature. The mixture of producer gas and gas from the retort is treated to separate the low-temperature volatile oils, and is then mixed with the remaining producer gas from the other producers of the battery and treated for the recovery of ammonia as sulphate. The retort is of the revolving type, and is of such construction as to provide sufficient solid fuel for use in all the producers, a measured quantity being fed to the producer which generates the gas employed for heating the material in the retort.—A. G.

Hydrocarbon vapours or gases; Process for generating and utilising ——. J. P. Kendall, Assr. to Kendalite Co., Inc. U.S.P. 1,376,100, 26.4.21. Appl., 14.3.18.

To prevent accumulation of carbon deposits in a hydrocarbon vapour generator for intermittently operated burners, barium oxide is heated in the generator in the presence of air until partially converted into barium peroxide. A hydrocarbon liquid containing an oxidising agent is then charged into the generator and the heating is continued to vaporise the liquid and convert a further portion of the barium oxide into peroxide. The vapour is burnt outside the generator to continue vaporisation and to convert the barium peroxide into oxide with simultaneous oxidation of any carbon deposits. As the apparatus cools, a portion of the barium oxide is reconverted to peroxide.—L. A. C.

Gas producers with inner distillation chamber; Packing for ——. F. Siemens. G.P. 330,278, 30.6.17.

IN a gas producer provided with separate outlets for the products of distillation and gasification and with a rotating distillation chamber, loss of gas on the one hand or admixture of air with the gas on the other hand, in the event of defective packing, is prevented by enclosing the joint between the rotating and fixed parts of the apparatus in a chamber filled with the gases generated in the lower part of the apparatus. The gases from the upper part of the apparatus pass out through an annular space between the charging device and the rotating distillation chamber.—L. A. C.

Gas-producer. R. Bergmans. G.P. 330,728, 1.1.19.

THE space below the hearth of a gas producer is divided into two compartments by means of a partition. Into one of these, below the combustion chamber, the air for combustion is introduced, whilst the gases from the combustion chamber are passed into the second compartment, which is beneath the gas exhaust chamber. Admixture of oxygen with the combustion gases is thus prevented. —W. J. W.

Gas and coke; Production of —— and recovery of by-products. W. Zimmermann. G.P. 334,002, 4.7.18.

COAL is heated by passing gas through it until low-temperature tar is formed, after which degasification is continued by means of external heating and a solid coke is obtained.—W. J. W.

Ammonia; Extraction of —— from gases. E. L. Pease. E.P. 162,314, 29.10.19.

GAS is passed through a pipe along which a dry material containing aluminium sulphate is conveyed in the reverse direction. The absorbent material is prepared by heating shale or clay with sulphur and coke in a gas producer and collecting the ash.—C. I.

Ammonia and tar recovery process. J. Van Ackeren, Assr. to The Koppers Co. U.S.P. (A) 1,375,475, (B) 1,375,476, (C) 1,375,477, and (D) 1,375,478, 19.4.21. Appl., (A and B) 21.8.19, (C and D) 25.8.19.

(A) PRODUCER gas is freed from dust, washed while still hot with water, further cooled to remove tar, and washed with acid. (B) Steam is generated by the heat of the gas leaving the producer and used for blowing the producer after passing through a gas-fired superheater. (C) Gas at its saturation temperature is washed with acid and the dilute

mother liquor concentrated with superheated air, which air, thus saturated with moisture, is used in the producer. (D) Hot gas free from dust is blown through condensed ammonia liquor to distil the ammonia, and the mixed still vapours and dust-free gas are freed from tar and moisture in an electrical precipitator and then washed with acid. —C. I.

Ammonia and tar recovery process. J. Becker, Assr. to The Koppers Co. U.S.P. (A) 1,375,483, (B) 1,375,484, and (C) 1,375,485, 19.4.21. Appl., 21, 22, and 25.8.19.

(A) Producer gas is cooled and freed from dust and tar, and the ammonia removed in an acid washer so operated that the gas effects the concentration of the ammonium sulphate liquor. (B) Gas is cooled and freed from tar by a counter current of air and the heated air used to concentrate ammonium sulphate liquor. (C) Superheated air is used to concentrate the sulphate liquor and the air after reheating supplied to the producer.—C. I.

Sulphur; Removal of —— from gases. N. E. Rambush. E.P. 162,554, 21.5.20.

In the removal of sulphur from a gas by washing with a suspension or solution of a metallic compound and revivifying the sludge produced with a current of air, a sensible loss of sulphur occurs in the latter stage. To reduce this loss to a minimum the air is circulated, with admission of enough fresh air to maintain the oxygen content at about 8%; or air may be drawn in slowly as the liquid flows down a tower, by chimney draught and by the injector action of the inflowing liquid.—C. I.

Oil; Recovery of —— from substances such as bitumen and shale in situ. D. Diver. E.P. 162,337, 23.12.19.

Two bore holes close together in the shale or the like contain metal cylindrical casings, one of which is closed and contains a series of electric heating coils, while the other is perforated for a portion of its length at the lower end, and is provided at the top with a cup and an outlet pipe for conveying vapours to a condenser and gas storage plant. The heat generated in the first casing heats the surrounding rock and decreases the viscosity of the oil therein, which flows through the perforations into the second casing, whence it is removed by pumping or other means, while the lighter fractions are volatilised and pass out through the pipe at the top.—L. A. C.

Liquid fuel; Process of treating ——. E. E. Wickersham. U.S.P. 1,376,180, 26.4.21. Appl., 26.9.20.

By passing electric sparks through liquid fuel, the final boiling point is reduced.—D. F. T.

Oil mixtures [e.g., shale oil]; Process for separating ——. K. Kubierschky. G.P. 333,294, 2.12.17.

Oil mixtures are dissolved in alcohol of a high strength and the solution is then washed in a counter-stream of water or aqueous alcohol. To separate shale oil (sp. gr. 0·900) into two fractions of sp. gr. 0·93 and 0·84 respectively, the crude oil is washed with an equal quantity of 90% alcohol, the resulting solution having a sp. gr. of 0·866. By introducing water into the upper end of the washing column, a mixture of 80% alcohol and the extract gradually forms at the bottom and can be drawn off, whilst the oil (sp. gr. 0·84) which separates from the extract passes out at the top. —W. J. W.

Lubricants; Production of ——. H. W. Klever. G.P. 331,504, 2.2.15.

Small amounts of fatty acid salts of alkaline-earth or heavy metals dissolved in coal-tar oils increase their viscosity appreciably and their power of adhesion to metallic surfaces.—W. J. W.

Lubricants; Manufacture of ——. P. Friesenhahn. G.P. 332,909, 25.7.19.

Hydrogenised phenols or their derivatives, such as cyclohexanone and its homologues, or cyclohexanol and its esters, may be used, either alone or mixed with other lubricants, as lubricating agents. Cyclohexanol has sp. gr. 0·945, b.p. 160° C., and viscosity 3·5° (Engler), and readily mixes with fats, oils, and hydrocarbons.—W. J. W.

Crude oil refining processes and apparatus. J. G. P. Evans. E.P. 162,873, 9.3.20.

See U.S.P., 1,366,643 of 1921; J., 1921, 172 A.

Furnaces for pulverulent fuel [for locomotives]. Motala Verkstads Nya Aktiebolag, and K. H. W. von Porat. E.P. 162,896, 29.3.20.

Gas producers; Charging devices for ——. K. Linck. E.P. 148,239, 9.7.20. Conv., 2.2.18.

[Gas] retort settings; [Division walls for] vertical ——. Drakes, Ltd., and J. W. Drake. E.P. 162,422, 9.2.20.

Gas producers, furnaces, and the like; Gas regulating and reversing valves for ——. W. Simons and I. B. Evans. E.P. 162,564, 2.6.20.

See also pages (A) 422, *Stills* (E.P. 162,000). 427, *Products soluble in or forming emulsions with water* (E.P. 134,223); *Asphalt substitute* (G.P. 332,888). 435, *Separating slag from coke, etc.* (E.P. 152,642). 449, *Petroleum preparation* (G.P. 334,916).

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Adsorbing power of charcoal; Determination of ——. I. M. Kolthoff. Pharm. Weekblad, 1921, 58, 630—656.

Freundlich's rule, that the order in which materials are adsorbed is almost independent of the nature of the solid phase, is found to hold for five kinds of charcoal tested with many different substances. The order of the adsorbing capacity is:—Blood charcoal (M)>vegetable carbon (M)=medicinal carbon (M)>bactanate >norite (M indicates Merck's preparation). A test of adsorptive power is the weight of mercuric cyanide or phenol adsorbed by 1 g. of charcoal from 100 c.c. of $N/10$ solution. (*Cf.* J.C.S., June.)—S. I. L.

Patents.

Decolorising carbon; Method of making ——. C. S. Hudson. E.P. 139,156, 20.1.20. Conv., 15.2.19.

Carbonisable organic material is mixed with a fusible acid, *e.g.*, phosphoric acid, in the proportion of not less than 0·5 pt. (*e.g.*, 2 pts.) of acid to 1 pt. of organic material, and the mixture is carbonised at 375° C. or over.—A. G.

Decolorising charcoal; Process for the preparation of ——. De Bruyn, Ltd., and C. Revis. E.P. 162,117, 6.2.20.

Filter-press residues from the refining of edible oils, such as cottonseed oil and the like, are carbonised to produce a dry, porous carbonaceous material. The carbonisation takes place with the admission of a regulated quantity of air and the carbonised product is washed with a mineral acid

in order to neutralise the alkaline salts. After neutralisation, the mixture is formed into cakes and again heated to expel moisture and excess acid. —A. G.

Distilling carbonaceous material; Apparatus for ——. W. P. Perry. E.P. 162,136, 25.2.20.

An apparatus for distilling carbonaceous material consists of one structure divided by vertical or slightly inclined partitions into three chambers, the middle one, the distilling chamber, having a number of openings into the gas distributing chamber and the collecting or condensing chamber on either side. The two latter chambers have each a capacity equal to or greater than that of the distilling chamber.—A. G.

Carbonising apparatus. H. N. McLeod. U.S.P. 1,375,714, 26.4.21. Appl., 18.12.20.

A number of chambers are so arranged that the discharge end of one chamber leads into the receiving end of the next chamber in the series. The chambers are divided into two series with separate heating circuits, the heating circuit of the second set of chambers comprising a primary source of heated gas and conduits receiving the heated gas, the walls of the conduits being in contact with the material in the chambers of the second set. The flow of the heated gas through the conduits is in counter-current to the passage of the material through the chambers of the second set. Condensing apparatus is connected with the last chamber of the second set. Conduits having walls in contact with the material in the chambers of the first set receive the heated cooling medium from the jackets of the condenser and convey it in counter-current to the material to be carbonised through the chambers of the first set. The material to be carbonised is conveyed mechanically through the chambers of the first set and then through the chambers of the second set.—A. G.

Distillation; Furnace system for dry ——. T. M. U. von Post. U.S.P. 1,375,943, 26.4.21. Appl., 16.10.19.

The retort proper is inserted in a closed chamber and is provided with a conduit communicating with an inlet at the bottom of the chamber, gases being conducted from the inlet into the top of the retort. The retort is also provided at the bottom with an outlet communicating with an outlet pipe opening into the bottom of the chamber, where means are provided by which the outlet and the inlet are separated from each other by a gas-tight joint. A condenser communicates with the inlet and the outlet.—A. G.

Distillation of wood, charcoal, or peat; Apparatus and process for continuous ——. Köln-Rottweil, A.-G. G.P. 326,227, 21.10.19.

In a process in which the material is distilled either at normal or elevated pressure or *in vacuo*, in horizontal retorts into which it is introduced in counter-current to the heating gas, the charge is first compressed in a suitable machine and then delivered to a screw-conveyor, the latter having a scraper which causes uniform amounts of the pressed material to be introduced into the retort. To ensure rapid and regular heating, the material is kept in motion in the retort; the products of distillation must be rapidly removed.—W. J. W.

Retort for distillation of carbonaceous materials. H. Graf. G.P. 328,821, 3.5.19.

The retort, in which the charge is carbonised from the top downwards, is surrounded by a cooling chamber which communicates with it by means of openings through which the products of distillation pass. A water pipe through the outer chamber serves to condense some of the products, which are drawn off through a pipe at the bottom, whilst the uncondensed gases escape through a pipe which passes centrally upwards through the retort. A high yield of condensed distillation products is thus obtained.—W. J. W.

III.—TAR AND TAR PRODUCTS.

Polycyclic phenols from sodium phenoxide fusions. F. Hofmann and M. Heyn. Brennstoff-Chem., 1921, 2, 147—150.

Sodium phenoxide was heated in a stream of hydrogen or nitrogen at 485°—490° C. Four of the six possible isomeric dihydroxydiphenyls were isolated from the residue. (*Cf.* J.C.S., July.) —W. P.

Diphenylamine; Melting point of ——. H. Rogers, W. C. Holmes, and W. L. Lindsay. J. Ind. Eng. Chem., 1921, 13, 314—316.

The m.p. of pure diphenylamine was found to be 53·0° C., which is 1° lower than the value given in the literature.—W. P. S.

Benzene hydrocarbons in gas. Krieger. *See* IIa.

Paraffin from lignite tar. Seidenschnur. *See* IIa.

Aniline bisulphate. Sabalitschka. *See* VII.

Patents.

Products [from tar] soluble in or forming emulsions with water; Process for the manufacture of ——. M. Melamid and L. Grötzinger. E.P. 134,223, 22.10.19. Conv., 31.10.17.

The solid or semi-solid resin-like substances, prepared from soft pitch, coal tar, lignite tar, or the like by extraction with sodium hydroxide solution with subsequent acidification of the extract, are distilled *in vacuo*; the portion distilling above 270° C. (20 mm.) is dissolved in cold sodium hydroxide solution, with or without previous sulphonation, and tar oil or mineral oil is added to the solution. The products are suitable for use as lubricants and as substitutes for soap and Turkey-red oil.—L. A. C.

Asphalt substitute; Manufacture of an ——. Verkaufsvereinigung f. Teererzeugnisse G.m.b.H. G.P. 332,888, 12.8.19. Addn. to 330,970 (J., 1921, 339 a).

Anthracene residues when treated with sulphur yield a product of high tenacity which is suitable for lacquers, briquettes, or road-making.—W. J. W.

Tar or tar residues, and filling material; Production of a homogeneous mass from ——. N. Reif. G.P. 332,941, 3.1.20.

Tar fog is caused to circulate and impinge on the periphery of a moving annular cloud of filling material so as to envelop and penetrate the latter. In order to obtain a product possessing hardness, elasticity, and resistance to heat, the tar, or a mixture of tar and oil, is first oxidised or treated with a halogen or sulphur and then incorporated with the filling material at a suitable temperature. —W. J. W.

Salts of sulpho-acids; Process for obtaining —— *from lignite tar oils.* Sudfeldt und Co. E.P. 148,763, 10.7.20. Conv., 14.3.19.

Lignite tar oils are treated with sufficient concentrated sulphuric acid to polymerise the acid resins,

i.e., 3 to 5% of their weight, and, after separation of the polymerisation products, with 10 to 20% of concentrated sulphuric acid to sulphonate the oil. After separation of the product into two layers, the oil layer is removed and agitated with an excess of $N/2$ sodium hydroxide solution to dissolve the sulphonic acids, which are then precipitated from solution by the addition of sodium chloride. The sulphuric acid layer is treated with a little water to remove excess sulphuric acid, the sulphonic acids are dissolved in water, and are precipitated from the filtered solution by the addition of sodium chloride. Sufficient saturated salt solution is first added to precipitate a small fraction of the product together with impurities, and, after separation of the precipitate, the remainder of the product is precipitated by the addition of more salt. The product is purified by treatment with oxidising agents, *e.g.*, permanganates, in aqueous solution. —L. A. C.

Naphthylamine sulphonic acids; Manufacture of ——. South Metropolitan Gas Co., and H. Stanier. E.P. 161,859, 25.5.20.

The separation of the 1.4.8- and 1.3.8-naphthylaminedisulphonic acids from the crude mixture obtained by the sulphonation of naphthylamine is effected by taking advantage of the differences in solubility of the barium salts of the acids. A suitably concentrated solution of the disodium salts is boiled with a quantity of barium chloride sufficient to convert all the acids into their barium salts. Barium 1.4.8-naphthylaminedisulphonate is precipitated, and the liquor is filtered hot. The filtrate and washings are acidified with hydrochloric acid, whereby the acid barium salt of the 1.3.8-disulphonic acid is precipitated, and filtered off hot to secure retention in solution of the corresponding salts of the 2.4.7- and 2.4.8-acids which may be present. Alternatively the barium salt may be added in proportion sufficient to convert only the 1.4.8- and 1.3.8-acids into barium salts, in which case the acid barium salts of the latter acid can be filtered off cold.—G. F. M.

Sulphur compounds of the thiophene series; Manufacture of ——. H. Scheibler. G.P. 331,793, 17.4.15. Addn. to 327,050 (J., 1921, 173 A).

The tar oil, after purification with soda-lime, is treated with sodamide or with ammonia and sodium below 120° C.—L. A. C.

Thionaphthene; Process of separating —— *from coal-tar* [*naphthalene*]. Ges. für Teerverwertung m.b.H. G.P. 333,156, 26.2.20. Addn. to 325,712 (J., 1920, 777 A).

The mixture of sulphonic acids, obtained as described in the chief patent, is distilled with steam at such a temperature that only a small proportion of the naphthalenesulphonic acid is hydrolysed. The distillate, m.p. 50°—60° C., containing 20 to 30% of thionaphthene, is treated with alkali for the removal of phenols, and is then purified by fractional distillation; the fraction 220°—225° C. gives a dark-red coloration on treatment in carbon bisulphide solution with sulphuric acid (sp. gr. 1·84). Steam distillation of the solution, after separation of the carbon bisulphide and dilution with water, yields pure thionaphthene.—L. A. C.

Anthranol; Manufacture of ——. A. G. Perkin, Assr. to British Dyestuffs Corp. U.S.P. 1,375,972, 26.4.21. Appl., 9.6.20.

See E.P. 151,707 of 1919; J., 1920, 743 A.

Lubricants. G.P. 331,504 and 332,909. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

Nitroamines and their derivatives; Some properties of ——. F. M. Rowe. J. Soc. Dyers and Col., 1921, 37, 145—150.

A review of the author's published work on nitroamines (J., 1913, 417; 1917, 958; 1918, 119 A). The nitrogen analogues of Stilbene Yellow and Mikado Orange can be prepared from *p*-nitroaniline by similar condensations to those which occur in the stilbene series. In the latter case the reaction is facilitated by the presence of negative groups in the *o*-position, but in the former case, sulphonic or nitro groups in the *o*-position with respect to the basic nitrogen exert an impeding effect in condensation, probably owing to a tendency to ring formation. The oxidation of an alcoholic solution of *o*-nitroaniline with neutral sodium hypochlorite results in the formation of 2.2′-dinitroazobenzene, but in presence of alkalis benziso-oxadiazole oxide is formed in quantitative yield. The latter compound yields a dinitro-derivative which forms true salts and affords an example of hydrogen in the benzene ring possessed of acidic properties. Dinitrobenziso-oxadiazole oxide, treated with sodium sulphide and sulphur by the condenser method, yields a fine brown sulphide dye of good properties, and thus suggests an outlet for *o*-nitroaniline. —F. M. R.

1.8-*Dihydroxynaphthalene.* G. Heller and H. Kretzschmann. Ber., 1921, 54, 1098—1107.

1.8-Dihydroxynaphthalene, m.p. 140° C., is most conveniently prepared by heating 1.8-dihydroxynaphthalene-4-sulphonic acid with sulphuric acid and water at 150° C. It couples with an equimolecular quantity of benzenediazonium chloride in hydrochloric acid solution to 4-benzeneazo-1.8-dihydroxynaphthalene, which does not melt below 260° C.; the same substance is formed in acetic acid or alkaline solution but, in addition, about 10% and 7·5% respectively of products insoluble in alkali are produced. The use of an increased proportion of diazo-compound leads, in acetic acid but not in mineral acid solution, to the production of 4.5-dibenzeneazo-1.8-dihydroxynaphthalene, m.p. about 238° C.; in alkaline solution, an isomeric dibenzeneazo dye appears also to be formed. 4-*p*-Sulphobenzeneazo-1.8-dihydroxynaphthalene dyes unmordanted wool a dark cherry red, a paler shade being produced on aluminium-mordanted wool and dark brown shades on the chrome-mordanted fibre. (*Cf.* J.C.S. July.)—H. W.

Azo components; Aromatic acylamines as ——. W. König and K. Köhler. Ber., 1921, 54, 981—987.

Diazotised *p*-nitraniline couples with *p*-toluenesulphon-α- and -β-naphthylamides, giving compounds of the type

$$O{:}N.C_6H_4.N{:}N.C_{10}H_6.N{:}S({:}O).C_6H_4.CH_3;$$
O .... Na .... O

since reaction does not occur under similar conditions with the corresponding methylnaphthylamides, it appears probable that the naphthylsulphonamide couples in its enolic form,

$$C_{10}H_7.N{:}S({:}O)(OH).C_6H_4.CH_3.$$

Carboxyamides can also couple with diazotised *p*-nitraniline but reaction occurs extremely slowly. The auxochromic power of the different groups under consideration diminishes in the order, $-OH$, $-NH.SO_2.C_6H_4.CH_3$, $-NH.CO.C_6H_5$, $-NH.CO.CH_3$. (*Cf.* J.C.S., July.)—H. W.

Isatins; Synthesis of ——. *Action of chloraloxime on aromatic amines.* T. Martinet and P. Coisset. Comptes rend., 1921, 172, 1234—1236.

In acid solution chloraloxime condenses with aniline to give isonitrosoacetanilide, which when warmed

with sulphuric acid yields isatin. If the aniline is replaced by p-chloro-o-anisidine hydrochloride the products are in turn 2-methoxy-5-chloroisonitrosoacetanilide, m.p. 190° C., and 4-chloro-7-methoxyisatin. The latter gives the corresponding copper and barium isatates and when condensed with indoxyl yields 4-chloro-7-methoxyindirubin, which with hydrosulphite gives an unstable yellowish-green vat changing almost completely into ordinary indigo.—W. G.

Isocurcumin. III. G. Heller. Ber., 1921, 54, 1118—1119.

EXAMINATION of the action of acetylacetone on p-hydroxybenzaldehyde and thymolaldehyde in the presence of alcoholic hydrogen chloride has shown that the poor yield of β-isocurcumin obtained from vanillin under like conditions (J., 1914, 544) is due to the decomposition of acetylacetone by the alcoholic acid into acetone with which the aldehyde preferentially condenses.—H. W.

PATENTS.

Anthraquinone series; Manufacture of nitrogenous condensation products of the ——. Badische Anilin- u. Soda-Fabrik. G.P. 329,247, 16.6.14.

1-HALOGENANTHRAQUINONES or derivatives containing a reactive substituent in o-position to the halogen atom are heated with o-aminodiarylamines or their nuclear substitution products, alone or in an inert solvent or suspension medium, and with or without addition of catalysts and substances capable of combining with acids. Anthraquinonylbenzohydroazines of the formula,

$$C_6H_4<\genfrac{}{}{0pt}{}{CO}{CO}>C_6H_2<\genfrac{}{}{0pt}{}{NR}{NH}>C_6H_4$$

similar to the products described in G.P. 329,246 (E.P. 3347 and 100,581 of 1915; J., 1916, 831), are formed. From 1-chloroanthraquinone, o-aminodiphenylamine hydrochloride, potassium acetate, and naphthalene, a product of the composition, $C_{26}H_{16}O_2N_2$, insoluble in dilute hydrochloric acid, and crystallising from acetone in needles with a coppery lustre, is obtained. The same substance is formed from 1.2-dichloroanthraquinone, m.p. 202°—204° C., and from 1-bromo-2-methoxyanthraquinone, whereas from 1.5- or 1.8-dichloroanthraquinone two isomeric monochloro-derivatives of the substance are formed. With 1.4-dichloroanthraquinone both chlorine atoms are replaced, and a blue condensation product, almost insoluble in acetone, is obtained.

Anthracene derivatives containing nitrogen; Preparation of ——. Preparation of nitrogenous condensation products of the anthraquinone series. Badische Anilin- und Soda-Fabr. G.P. (A) 330,572, 14.8.14, and (B) 332,013, 16.6.14. Addn. to 329,247 (*cf. supra*).

(A) ALIZARIN or a heteronuclear hydroxy-substitution derivative (with the exception of 1.2.5.8-tetrahydroxyanthraquinone) is heated with primary aromatic amines or their substitution products with or without addition of stannous chloride. On heating alizarin with aniline and stannous chloride to 170°—180° C., phenylaminocoeramidonine is formed, which, after freeing the melt from excess of aniline by hydrochloric acid, is extracted with acetone, from which it crystallises in glistening needles, m.p. 203°—205° C. (uncorr.), soluble in alcohol, nitrobenzene, and aniline with a red, and in concentrated sulphuric acid with a greenish blue colour. Other arylaminocoeramidonines from p-toluidine and alizarin (m.p. 198°—199° C.), 1.2.6-trihydroxyanthraquinone and p-toluidine (m.p. 284°—287° C.), 1.2.7-trihydroxyanthraquinone and p-toluidine, 1.2.5-trihydroxyanthraquinone and p-toluidine, and 1.2.5.6-tetrahydroxyanthraquinone and p-toluidine, are described. All these products can be used as dyestuffs or as raw materials for the preparation of dyestuffs. Their sulphonic acids dye unmordanted wool in red, violet, and blue shades. (B) Arylaminoanthraquinones, or their nuclear substitution products, containing a reactive substitution group in the ortho-position to the imino-group, are condensed with primary aromatic amines. Thus 1-phenylamino-2-methoxyanthraquinone is produced from 1-bromo-2-methoxyanthraquinone and aniline; it dissolves in sulphuric acid with a yellowish-red and in alcohol with a carmine-red colour. It gives a condensation product with aniline and caustic potash identical with that described in the principal patent.—A. R. P.

Diazo-azo-hydroxy compounds; Preparation of ——. O. Müller. G.P. 330,832, 7.4.16.

SUFFICIENT alkali carbonate is added to render alkaline a solution containing equivalent quantities of (A) a diazohydroxynaphthalene, or derivatives of the same, such as 1-diazo-5 (or 7)-hydroxynaphthalene, or 2-diazo-8-hydroxy-6 (or 3.6-di)-sulphonic acid, and (B) a highly reactive mono-diazo compound containing a negatively substituted benzene nucleus, such as p-nitrodiazobenzene. Alternatively, a solution of (B) is added to a solution of (A) containing sufficient alkali carbonate to render the solution alkaline at the end of the reaction, which is marked by the disappearance of both diazo compounds from the solution. The products couple, *e.g.*, with m-toluylenediamine, 1-aminonaphthalene-6 (7)-sulphonic acid, or 1-amino-8-hydroxynaphthalene-4-sulphonic acid, yielding dark blue to black substantive cotton dyes. Diazo-1-hydroxynaphthalene compounds which are capable of reacting with a diazo compound in both alkaline and acid solution, produce in the two cases different diazo-azo compounds, which yield different dyestuffs on coupling. —L. A. C.

Azo dyestuffs dyeing on mordants. C. Jagerspacher, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,375,701, 26.4.21. Appl., 15.11.19.

SEE E.P. 149,553 of 1919; J., 1920, 816 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Plant colloids. VIII. Some cellulose dextrins. M. Samec and J. Matula. Kolloid-Chem. Beih., 1921, 11, 37—73.

SULPHITE-CELLULOSE is not completely dissolved by 50% sulphuric acid, whilst 86% sulphuric acid chars it. Solutions of cellulose in sulphuric acid (50—85%) are at first colourless, but on keeping they speedily become coloured. As the degradation of the cellulose becomes greater the coloration produced by iodine changes from blue to violet, then to various shades of brown, and finally disappears; the relative viscosity rises to a maximum and then falls as the swelling and solution increase. In the degradation, dextrins are produced, some of which are soluble in water whilst others are insoluble. The insoluble products are destroyed by sulphuric acid (60% and above) within the first half hour. As the degradation proceeds the following changes are observed successively:—the dextrin esters are gelatinised by alcohol and the dextrin is precipitated; the dextrin esters and the dextrins are both insoluble in alcohol; the dextrin esters are soluble, the dextrins are insoluble in alcohol; both dextrin esters and dextrins are soluble in alcohol. Phosphoric acid of a greater concentration than 75% at ordinary temperatures forms a colourless, very viscous jelly with cellulose which is only slowly changed at this temperature, but at higher temperatures a

slow degradation occurs and eventually the solution becomes brown or black. The action of sulphuric acid on cellulose depends not only on the concentration of the acid but also on the relative quantities of acid and cellulose. With a sufficient excess of acid dialysable dextrins are produced in the first quarter of an hour and at the same time the molecular weight of the colloidal residue is reduced. The degradation of both dialysable and non-dialysable portions proceeds further by continued action of the acid until after 5 hours the mean molecular weight of the most coarsely disperse portion is 2400. At the same time the $-SO_4H$ group enters the molecule with the formation of esters. Diastase is capable of converting some of the dextrins produced into fermentable sugars. (*Cf.* J.C.S. June.)

Colophenic acids. Aschan. *See* XIII.

PATENTS.

Wool-washing machines. J. F. and W. H. White. E.P. 162,313, 8.10.19.

THE wool is carried forward over several consecutive hemi-cylindrical perforated surfaces by means of adjustable drums having projecting tangential beaks, whereby it is constantly immersed in the washing liquid. The tangential beaks are so shaped that there is no tendency for the wool to lap around them.—A. J. H.

Fireproofing material and heat- and cold-retaining coverings; Process of making —— and product thereof. C. S. Hathaway, Assr. to J. A. Locke. U.S.P. 1,374,885, 12.4.21. Appl., 24.3.20.

A FABRIC is impregnated with a composition containing a tar and an hydraulic cement.— H. S. H.

Sulphate pulp; Manufacture of ——. E. Olsson. U.S.P. 1,375,759, 26.4.21. Appl., 2.4.19.

A DIGESTION liquor containing sodium hydroxide and a larger amount of sodium sulphide is used.
—A. J. H.

Articles obtained from solutions [cellulose and the like]; Process for the production and simultaneous conversion of —— into their ultimate forms. B. Borzykowski. U.S.P. (A) 1,375,823 and (B) 1,375,824, 26.4.21. Appl., 29.5.17 and 19.6.20.

(A) ARTICLES are produced from solutions of viscose by "forming" and "setting" in a non-acid salt solution and are immediately afterwards converted into the final cellulose product. (B) Articles are produced by passing solutions, capable of coagulation, directly into an alkaline bath and are immediately afterwards subjected to an ultimate chemical conversion; *e.g.*, cellulose thread is produced by spinning a solution of cellulose into an alkaline bath, withdrawing the thread and winding it under tension and simultaneously converting it into cellulose hydrate by treatment with sulphuric acid.—A. J. H.

Fibres; Process for making ——. R. Kron. U.S.P. 1,376,285, 26.4.21. Appl., 18.9.19.

FIBRES which felt together not too densely and thereby produce an absorbent spongy sheet sufficiently strong and durable for application to the manufacture of rough pasteboard, which after saturation with tar or bitumen, is suitable for roofing, linings, etc., are produced (without the use of alkalis or acids) from wood in the form of logs and similar large pieces and from ligneous or strongly silicious plants. These materials are boiled with water or steamed, rolled out, crushed and ground so as to obtain the natural cellulose fibres without deterioration and not weakened by chemical reagents.—A. J. H.

Paper material coated with leaf metal. F. Tscheike, Assr. to The Chemical Foundation, Inc. U.S.P. 1,376,737, 3.5.21. Appl., 6.6.17.

Chlorate explosives. G.P. 307,100. *See* XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Anilides of β-[hydr]oxynaphthoic acid [in production of ice colours]. E. R. Brunskill. J. Ind. Eng. Chem., 1921, 13, 309.

ALTHOUGH the colours obtained by substituting β-hydroxynaphthoic acid for β-naphthol in the ice process are brighter, they are not fast to washing; to overcome this defect amides of the acid have been used, the chief of which is the anilide (Naphthol AS). Dyeing experiments were made with the following substances as naphthols:—β-hydroxynaphthoic acid, the anilide, the toluidide, and the *p*-chloroanilide; each naphthol was coupled with aniline, *p*-nitroaniline, *p*-chloroaniline-*o*-sulphonic acid, *p*-toluidine, *m*-nitro-*p*-toluidine and *o*-chloro-*p*-toluidinesulphonic acid. All the colours made from β-hydroxynaphthoic acid washed out, but the anilides gave fairly fast colours, except in the case of the sulphonated amides. The latter, however, were rendered fast by immersing the dyed fabric for 30 mins. in 3% calcium chloride solution at 50° C.—W. P. S.

PATENTS.

Dyeing; Method of ——. A. Lendle, Assr. to Kuttroff, Pickhardt and Co. U.S.P. 1,375,919, 26.4.21. Appl., 9.9.20.

FABRIC is dyed with a basic dyestuff and is subsequently treated with a complex acid containing phosphorus and tungsten. (*Cf.* E.P. 143,242; J., 1921, 385 A.)—A. J. H.

Decomposition products of proteins [protalbinic and lysalbinic acids]; Use of —— [in dyeing]. C. Bennert. G.P. (A) 331,484, 25.12.15, and (B) 332,476, 19.1.16. Addns. to 330,133 and 331,234 (J., 1921, 256 A, 297 A).

(A) The use of the decomposition products, prepared, *e.g.*, by heating casein or gluten with sodium hydroxide, is claimed in weakly alkaline, neutral, or weakly acid vats, but not in strongly alkaline vats. (B) In the case of sulphur dyes suitable for dyeing animal fibres, the vat is prepared by treating the dye with hydrosulphite and sodium hydroxide, and the alkali is neutralised by the addition of an acid or a neutral salt of a volatile alkali and an organic acid, *e.g.*, ammonium formate, together with the protalbinic and lysalbinic acids.—L. A. C.

Hosiery, gloves, and the like dyed with Aniline Black; Manufacture of ——. K. Schlatter. G.P. 332,675, 23.3.19. Conv., 21.11.18.

THE goods are made from raw yarn of which a part has been treated with a substance which prevents the injurious effect of the Aniline Black process (such as a metal oxide which can be printed on to the yarn, or a compound capable of combining with an acid or acting as a reducing agent) or of which a part has not been aged. A suitable method of manufacture is to employ double threads, in which one has been dyed with Aniline Black, and the other has been dyed with another black dye, or has been treated as described above.
—L. A. C.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrochloric acid; New method of purification of ——. J. Lamquet. Bull. Soc. Chim. Belg., 1920, **29**, 309.

COMMERCIAL hydrochloric acid may be freed from arsenic, chlorine, and sulphur dioxide by the simple addition of hypophosphorous acid or one of its salts, the reactions being represented by the following equations:

$3H_3PO_2+4AsCl_3+6H_2O=3H_3PO_4+12HCl+4As.$
$H_3PO_2+2Cl_2+2H_2O=H_3PO_4+4HCl.$
$H_3PO_2+SO_2=H_3PO_4+S.$

By using the barium salt sulphuric acid is precipitated at the same time.—G. F. M.

Glauber's salt; Manufacture of ——. W. Hüttner. Chem.-Zeit., 1921, **45**, 313—315.

THE waste product derived from the manufacture of potassium chloride and consisting chiefly of a mixture of rock salt and kieserite, may be utilised as raw material for the production of Glauber's salt. It contains approximately: KCl, 2·6%; $MgSO_4$, 10·5%; $CaSO_4$, 3·4%; NaCl, 54·3%; and Na_2SO_4, 6·9%. The waste heaps are sprinkled with water at 45°—50° C., until a solution is obtained of sp. gr. 1·27—1·29 and of the approximate composition: NaCl, 21·1%; $MgSO_4$, 9·1%; $MgCl_2$, 1·3%; H_2O, 68·4%. Formerly it was usual to crystallise this solution in winter at below 0° C., but artificial refrigeration is now adopted, the solution being placed in vats with cooling coils, and depositing fine crystals of Glauber's salt on cooling. The crystals are re-dissolved in steam-heated vessels and freed from iron by precipitation with lime; the solution is then allowed to crystallise again in such a manner as to yield either large crystals or a fine crystalline material, as required. To obtain a calcined product, suitable for glass works, the salt solution is evaporated in a vessel provided with copper heating coils, and the residue is dehydrated.—W. J. W.

Ammonia and carbonic acid; Compounds of —— *in equilibrium with their aqueous solutions.* E. Terres and H. Weiser. Z. Elektrochem., 1921, **27**, 177—193.

THE conditions under which the different compounds of ammonia and carbonic acid are stable in contact with aqueous solutions of the components were studied between 0·1° and 60° C. Five different compounds can exist as solid phases, namely ammonium bicarbonate, the bicarbonate-carbonate double salt, $2NH_4HCO_3,(NH_4)_2CO_3,H_2O$, the normal carbonate, ammonium carbamate, and the carbamate-bicarbonate double salt, $NH_4CO_2NH_2,NH_4HCO_3$. All these have distinctive crystalline forms by which they can be identified microscopically. Previously only the bicarbonate and carbamate had been prepared in the pure state, but methods have now been devised for preparing the bicarbonate-carbonate double salt and the normal carbonate. The former salt crystallises from solutions containing NH_3 and CO_2 in the ratio 4:5. The normal carbonate is prepared by dissolving 395 g. of ammonium bicarbonate in 150 g. of water and 333 g. of 25% ammonia solution whilst passing in ammonia under a pressure of 0·2 atm. and warming to 40° C. until solution is complete. On cooling to 10° C. the normal carbonate crystallises out. Only the bicarbonate forms congruent solutions, in which the ratio of NH_3 to CO_2 is the same as in the solid phase. The other compounds form stable solid phases only in presence of excess of ammonia. The equilibrium diagram shows that the normal carbonate and the two double salts have a limited temperature range of stability, whilst the bicarbonate and carbamate can exist at all temperatures between 0° and 60° C. with the necessary ammonia concentration. Starting with bicarbonate and water, between 0° and 33° C., as the concentration of ammonia increases the solid phase changes consecutively to bicarbonate-carbonate, normal carbonate, and finally carbamate. At about 33° C. both the double salt and normal carbonate disappear and the new double salt bicarbonate-carbamate appears between the bicarbonate and carbamate. No further change takes place up to 60° C.

—E. H. R.

Potassium, sodium, ammonium, and aniline bisulphates, potassium binoxalate and tetroxalate; Decomposition of —— *by solvents.* T. Sabalitschka and H. Schrader. Ber. deuts. Pharm. Ges., 1921, **31**, 183—198.

THE crystallisation of aqueous solutions of potassium, sodium, ammonium, and aniline bisulphates, results in the formation, to a greater or lesser degree, of the normal salt and the free acid. Thus pure potassium sulphate was deposited from a solution of pure potassium bisulphate, whilst a mixture of the normal and acid salts was obtained in the other cases. The addition of alcohol to an aqueous solution of sodium bisulphate caused the precipitation of the pure normal salt. The precipitate obtained in a similar way with ammonium bisulphate solution contained 60—70% of the normal salt. The prolonged extraction of the dry bisulphates with alcohol in a Soxhlet apparatus resulted in the removal of acid, leaving a residue of the normal sulphates in the case of the potassium and sodium salts, and a mixture in the case of the ammonium and aniline salts. The extraction of potassium tetroxalate with ether and alcohol resulted in a similar decomposition into free acid and potassium binoxalate, the latter being unchanged by further action of the solvents.—G. F. M.

Ammonium sulphate; Melting point of ——. J. Kendall and A. W. Davidson. J. Ind. Eng. Chem., 1921, **13**, 303—304.

DIVERGENT figures for the melting point of ammonium sulphate must be ascribed to the instability of the normal salt (*cf.* Watson Smith, J., 1895, 629). Results obtained by many observers for the melting point of the acid salt are in close agreement with Kendall and Landon's figure, 146·9° C. (J. Amer. Chem. Soc., 1920, **42**, 2131), and a melting point of 251° C., given by Jänecke (J., 1920, 818 A), is explicable. The actual melting point of the normal salt can be determined only by heating it in a sealed tube, with no free air space, so as to avoid appreciable loss of ammonia. Under these conditions the salt softened at 490° C. and its melting point was found to be 513° C.±2°, under an ammonia pressure of considerably more than 1 atm.

—W. J. W.

Bleaching powder; Solution of ——. M. Champion. Bull. Soc. Chim. Belg., 1920, **29**, 24—28.

MIXTURES of bleaching powder and water containing from 1 to 20% of the former were shaken for 3 hours, allowed to settle, and in the clear supernatant solution the active oxygen, total chlorine and calcium, and the density were determined. If the concentration exceeds 4% there is a risk of some of the active oxygen being retained in the residual sludge from the preparation. The figures on the whole show rather higher proportions of calcium and total chlorine to active oxygen than those required by the formula, Cl.CaOCl.—W. G.

Reaction $CaCO_3=CO_2+CaO$*; Reversibility of the* ——. P. Jolibois and Bouvier. Comptes rend., 1921, **172**, 1182—1183.

USING various forms of calcium carbonate, it was found that the reversal of the dissociation on cool-

ing was never complete except when precipitated calcium carbonate was dissociated by heat in the presence of an excess of calcium oxide.—W. G.

Calcium carbide; Apparatus and method for estimation of ——, for calcium cyanamide manufacture. E. von Drathen. Chem.-Zeit., 1921, 45, 447.

Twenty grms. of carbide is placed in a stoppered separating funnel, the tap of which has a conical bore, varying in diameter from 1·5 mm. to 2·5 mm., so that when it becomes choked the particles are easily dislodged by turning through 180°. The funnel is fixed in a filter-flask containing a saturated solution of salt, and connected by tubing with a gas-measuring flask. This latter has a capacity of 5 l. and is graduated in 50 c.c. divisions; its lower end is continued as a long tube of 800 c.c. capacity graduated in 10 c.c. divisions, and this is in communication with a levelling flask. The volume of the acetylene generated by introduction of the carbide into the salt solution may be read to within 5 c.c.—W. J. W.

Chrome alum solutions; Action of sodium carbonate on ——. L. Meunier. J. Soc. Leather Trades' Chem., 1921, 5, 103—111.

As a result of Burton's experiments (J., 1921, 19 A) the author has carried out further work on the action of sodium carbonate in precipitating chrome alum solutions. The amount of sodium carbonate necessary to bring about the commencement of precipitation is less when the solution of chrome alum is more dilute, when the temperature is higher, when the solution is old, and when it is stirred vigorously. A reversible change takes place in chrome alum solutions which have been heated for some time at a constant temperature, but the change is irreversible if the heating has been prolonged or has taken place at 100° C. or above. Sodium carbonate precipitates a basic chromium sulphate from chrome alum solutions heated to 100° C. and chromium hydroxide from cold or freshly prepared solutions. Chrome alum solutions undergo hydrolysis and the basic chromic salts so formed polymerise under the action of heat and more slowly on keeping. Precipitation is due to the sodium carbonate acting as a neutralising agent and also as a coagulating agent on the chromium hydroxide or the polymerised basic chromium salts in colloidal solution.—D. W.

Phosgene; Solvents for ——. C. Baskerville and P. W. Cohen. J. Ind. Eng. Chem., 1921, 13, 333—334.

One part by weight of phosgene (carbonyl chloride) is dissolved by the following weights of different solvents at 20°—21° C.:—Carbon tetrachloride, 3·6; chloroform, 1·7; gasoline, 1·2; paraffin oil, not soluble; Russian mineral oil, 2·8; benzene, 1; toluene, 1·5; glacial acetic acid, 1·6; ethyl acetate, 1; chlorocosane, 3·2. The last substance is paraffin which has been melted and treated with chlorine. In the case of gasoline, chloroform, and glacial acetic acid reaction was evident by heat of solution and change in b.p. of the solvent; there was also a change in the b.p. of the toluene, but the other solvents appeared to be inert towards the gas. —W. P. S.

Sodium-oxygen cell. Baur. *See* XI.

Oxidation of sulphur. MacIntire and others. *See* XVI.

Titration of boric acid. Boëseken and Couvert. *See* XVII.

Patents.

Nitric acid; Manufacture of concentrated ——. Bayerische A.-G. f. Chem. und Landwirtschaftl. Fabrikate, H. Hackl, and H. Bunzel. G.P. 307,601, 9.3.16.

Barium nitrate is heated with sulphuric acid in a vessel through which the mixture is conveyed by a screw device in order to allow of a continuous process.—W. J. W.

Protection of walls of enclosures in which reactions [e.g., synthesis of ammonia] take place under high temperatures and pressures. "L'Air Liquide," Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 140,083, 9.3.20. 18.12.18.

The chamber in which the reaction takes place, being incapable of resisting a very high pressure, is enclosed in a pressure-resisting outer vessel which must be protected from the reacting substances (*e.g.*, gaseous hydrogen). The vessel is therefore filled to a level above the zone of reaction with a liquid that is neutral to the reacting substances and a bad conductor of heat (*e.g.*, potash-soda mixture). To prevent loss of heat by convection the space between the reaction chamber and the outer walls is filled with overlapping rings made of a solid which is also a bad conductor of heat and preferably may be capable of removing any corrosive substance dissolved in the liquid (*e.g.*, rings of magnetic oxide of iron will absorb hydrogen with formation of water vapour, which in turn may be absorbed by metallic iron placed inside the vessel but above the zone of reaction and out of the intense heat).—B. M. V.

Aluminium chloride; Production of ——. M. Shoeld, Assr. to Armour Fertilizer Works. U.S.P. 1,375,116, 19.4.21. Appl., 5.11.20.

Alumina is heated to 1600°—2000° C. to render it anhydrous, and is then subjected to the action of chlorine, in presence of carbon.—W. J. W.

Perborates; Manufacture of ——. J. K. Langhard, Assr. to Frederikstad Elektrokem. Fabr. A./S. U.S.P. 1,375,596, 19.4.21. Appl., 6.2.20.

A solution of a borate is electrolysed in presence of a cyanogen compound.—C. I.

Per-salts and metallic peroxides; Process for rendering —— stable by coating them with gelatin or glue. H. E. Bergmann. G.P. 334,868, 1.5.19.

The gelatin or glue solution is first oxidised to destroy reducing impurities and thus avoid loss of active oxygen in the compound to be preserved. The stabiliser may be applied to the reagents before preparation of the peroxides etc., as it does not interfere with the reaction.—C. I.

Arsine, phosphine, and stibine; Process and apparatus for electrolytic generation of ——. H. Blumenberg, jun. U.S.P. 1,375,819, 26.4.21. Appl., 11.6.19.

A compound containing phosphorus, or other element of the phosphorus group (nitrogen and boron excepted), is electrolysed in conjunction with a reagent capable of forming nascent hydrogen at the cathode and oxygen at the anode, and the gases formed are collected.—A. J. H.

Basic zirconium sulphate; Process of making ——. E. J. Pugh, Assr. to Pennsylvania Salt Manufacturing Co. U.S.P. 1,376,161, 26.4.21. Appl., 30.1.19.

Chlorine is passed over the heated ore and the sublimate of zirconium chloride dissolved in water. Basic zirconium sulphate is precipitated from this solution by addition of sulphuric acid.—A. R. P.

Magnesium bisulphite solution and magnesium oxide; Process of making ——. P. and A. Frank and M. Lebram. G.P. 302,472, 8.9.15.

Magnesium sulphate is converted into oxide by heating with sawdust or other carbonaceous material, and half of the oxide is transformed into bisulphite by saturating with the sulphur dioxide evolved. Excess carbonaceous matter is burnt off. —C. I.

Alumina; Process for the preparation of —— suitable for the manufacture of aluminium. M. Buchner. G.P. 303,923, 10.9.16.

The crude ore is decomposed with sulphuric acid, freed from iron, and the purified aluminium salt treated with enough ammonia to precipitate basic sulphate. The precipitate is washed, dried, and ignited in a current of air, the sulphur trioxide and ammonia evolved being recovered. The alumina produced is granular and not powdery.—C. I.

Nitrogen; Process for the oxidation of ——. Gewerkschaft des Steinkohlenbergwerks Lothringen, and M. Kelting. G.P. (A) 329,846 and (B) 329,847, 17.12.19.

(A) In a process for the oxidation of nitrogen heated to over 1500° C., the mixture of oxides of nitrogen from the reaction vessel is passed at a high speed (at least 5 m. per sec.) through a preheater consisting of narrow tubes of zirconia. In the reaction vessel a contact body is arranged, the active surface of which is several times that of the catalytic preheater surface. (B) The entering gases are passed through a heating chamber with refractory lining connected with a number of pipes, the front portions of which are insulated. After undergoing the reaction the gases pass on through pipes constricted to a small diameter into a cooling chamber, which may itself be formed of pipes set at right angles to the direction of the current of gas.—C. I.

Titanium tetrachloride; Process for manufacturing ——. O. Priesz. G.P. (A) 334,248 and (B) 334,249, 10.10.17.

(A) In the manufacture of titanium tetrachloride by passing chlorine over a heated mixture of titanic acid and charcoal, the activity of the chlorine is increased, and the reaction temperature reduced to below 300° C., by adding a small amount of an oxide or chloride of a rare earth metal, or of a metal of the manganese group, *e.g.* cerium, zirconium, or manganese. (B) In the treatment of titanic acid by heating it with a mixture of carbon monoxide and chlorine, the addition of small amounts of carbon to the titanic acid increases the yield of titanium tetrachloride.—W. J. W.

Magnesium hypobromite; Preparation of insoluble basic ——. E. Merck and W. Pip. G.P. 334,654, 12.6.19. Addn. to 297,874.

A mixture of a solution of a magnesium salt and an alkali or alkaline-earth hydroxide is treated with an equivalent weight of hypobromous acid or the corresponding amount of liquid or gaseous bromine. The basic hypobromite is deposited in a gelatinous state and dries to a yellow powder almost insoluble in water.—C. I.

Sulphur; Treatment of mined ——. R. F. Bacon and H. S. Davis, Assrs. to Texas Gulf Sulphur Co. U.S.P. (A) 1,374,897 and (B) 1,374,898, 19.4.21. Appl., 6.10.19.

(A) The free burning quality of mined sulphur containing oil is improved by heating it to 400°—430° C. for a sufficient time to carbonise the oil. (B) Crude sulphur containing oil is refined by heating it to carbonise the oil, then allowing the mass to cool to a temperature above the melting point of sulphur and stand until the carbon has segregated. —A. R. P.

Sulphur; Process for recovering —— from sulphates, especially calcium sulphate. Metallbank und Metallurgische Ges. A.-G. G.P. 334,247, 23.12.16.

In calcining a mixture of sulphate and fuel, the depth of the layer of the material and the introduction of air are so regulated that the surface of the material retains a dark appearance during the process. By this means the greater part of the combined sulphur is recovered in the free state. —W. J. W.

Caustic soda or soda lye; Prduction of ——. Schweizerische Sodafabrik. E.P. 144,266, 17.5.20. Conv., 4.6.19.

See G.P. 332,003 of 1919; J., 1921, 301 A.

VIII.—GLASS; CERAMICS.

Glass; Dissolved gases in ——. E. W. Washburn, F. F. Footitt, and E. N. Bunting. Univ. Illinois Bull. 15, Vol. XVIII., 13.12.20. 32 pages.

The percentage of gases dissolved in various samples of glass was determined by melting the sample under atmospheric pressure in an electric resistance furnace connected by means of a valve with a large evacuated tank with an internal pressure of less than 1 cm. and sometimes 0·02 mm. of mercury. When the glass was at a suitable temperature the valve was opened quickly, thus causing a sudden drop of pressure in the furnace and causing the glass to effervesce vigorously and to expand rapidly to about six times its original volume. In a modified form of the apparatus, the furnace consisted of a porcelain tube 3 cm. diam. and 13 cm. high, wound with platinum wire, surrounded by a tightly fitting porcelain protection tube, then by a second porcelain tube, the whole being enclosed in glass. The sample weighing about 25 g. was heated *in vacuo* to 1400° C. until no more gas was evolved. A barium flint optical glass with a refractive index of 1·605 yielded 15·3 c.c. of gas per 50 g. of glass, or 110% by vol. Two other samples yielded 50% by vol. of gas; the gas contained 25% CO_2 and 75% O_2. A light flint bulb glass gave 20% by vol. of gas consisting of CO_2 58%, O_2 24%, and N_2 18%. A borosilicate glass gave 20% by vol. of gas consisting of CO_2 26%, O_2 37%, and N_2 37%. The amount and

composition of the gas varied with the type of glass and the conditions of melting and plaining. The results obtained indicate that if glass were melted on an industrial scale in a vacuum furnace, the customary plaining would be eliminated, thus reducing the temperature necessary for finishing the glass, and the yield of perfect glass would be increased owing to the absence of all "seed." (*Cf.* J.C.S., June.)—A. B. S.

Patents.

Furnaces for melting glass. The E. W. Harvey Gas Co., and E. W. Harvey. E.P. 162,232, 16.9.20.

Heating of the glass near gathering or tapping openings of gas-fired glass-melting furnaces with one or more reversible flames is secured by providing supplementary flues in suitable positions near these openings. The flues, which are regulated by dampers, are connected directly with the chimney, and so have a stronger draught than that in the main ports or waste gas flues, these being only indirectly connected with the chimney through regenerators. The method may be applied to various types of tank and pot furnaces.—A. C.

Quartz glass; Process for making articles of ——. J. Scharl, Assr. to General Ceramics Co. U.S.P. 1,375,657, 19.4.21. Appl., 8.2.19.

Quartz glass is fused to a plastic mass in an electric furnace provided with a resistance core. The fused mass is removed from the furnace together with the hot core and blown into the desired shape. —J. S. G. T.

Dental cements; Manufacture of ——. S. Schiff. E.P. 161,868, 16.6.20. Addn. to 145,052.

In the manufacture of dental cements of the kind where a powder is mixed with a liquid to produce a composition which hardens to a solid cement, colloidal silica is added for the purpose of increasing the hardness and transparency of the product. —H. S. H.

Bricks, slabs, and the like; Method for treating clayey material for making ——. C. W. Wallace. E.P. 162,483, 11.3.20.

The bricks etc. are formed from the clayey material and passed directly into an ordinary working furnace, where they are well heated throughout by direct contact with the flames of the furnace. They are then withdrawn from the furnace and cooled suddenly by plunging them totally into water. A dense compact brick is thus formed from clayey materials (*e.g.*, certain African clayey materials similar to kaolin) which, if prepared and fired in the usual manner, give products which are too soft and porous to be of real service.—H. S. H.

Graphite crucibles; Method of making ——. *Method of making clay and graphite crucibles.* J. H. L. De Bats, Assr. to Lava Crucible Co. of Pittsburgh. U.S.P. (a) 1,374,909 and (b) 1,374,910, 19.4.21. Appl., 31.5.18. Renewed 5.8.20.

(a) Non-ferrous metal is mixed with the material, containing clay, from which the crucible is made, giving, in use, a surface coating of metallic silicate. (b) By mixing finely-divided metal of the aluminium-magnesium group with material containing clay used for making crucibles, the latter may be burned shortly after moulding.—A. C.

Highly-refractory article, and method of producing same. H. H. Buckman and G. A. Pritchard, Assrs. to Buckman and Pritchard, Inc. U.S.P. 1,375,077, 19.4.21. Appl., 9.10.19.

Zircon is added to the batch for making refractory material.—A. C.

Refractory material. M. L. Hartmann, Assr. to The Carborundum Co. U.S.P. 1,376,091, 26.4.21. Appl., 17.5.20.

A refractory article contains carborundum and a bonding material containing mixtures of zirconium and aluminium silicates.—H. S. H.

Brick-kiln. F. Munhollon. U.S.P. 1,375,719, 26.4.21. Appl., 29.12.19.

A brick kiln has a series of furnaces spaced about the outer wall. Transverse passages run beneath the floor of the kiln, and are connected by other passages with the furnaces. The openings into the transverse passages vary in size according to their distance from the furnaces.—H. S. H.

Annealing furnaces for glass-ware and the like. H. M. Thompson. E.P. 140,817, 26.3.20. Conv., 1.6.18.

See U.S.P. 1,281,713 of 1918; J., 1919, 16 a.

IX.—BUILDING MATERIALS.

Patents.

Porous cement or mortar products; Manufacture of ——. A. Sinding-Larsen. E.P. 146,172, 25.6.20. Conv., 3.7.19.

A substance (*e.g.*, aluminium powder), which is capable of reacting with water and alkaline solutions to form a non-volatile compound and hydrogen, is mixed with Portland cement or other mortar. The large volume of hydrogen evolved causes the product to be very porous. It is of advantage to mix the substances in a dry state and to use hot water or a solution of caustic alkali.—H. S. H.

Stone-like materials of foam-like structure; Method for manufacturing ——. E. C. Bayer. E.P. 162,318, 17.11.19.

Stone-like material permeated with air-filled pores is made by mixing together diatomaceous earth and powdered felspar or rocks containing felspar, forming the mixture into the desired shape with the addition of a little water, and heating to the fusing point of the mixture (about 1200°—1300° C.). The particles of air contained in the diatomaceous earth expand under this treatment and are surrounded by softened or fused solid matter which forms dense walls on cooling.—H. S. H.

Slag; Process for reducing fused —— *to granular form.* M. Maguet. E.P. 162,375, 26.1.20.

A jet of highly-heated basic slag from a blast furnace is divided into drops by means of an air blast directed against it. The temperature of the slag is thereby lowered to about 1300° C. On dropping into water the slag forms granules suitable for use in the manufacture of slag cements and bricks.—H. S. H.

Plastic composition for producing a jointless floor covering. M. Roberts. E.P. 162,514, 6.4.20.

A plastic composition is produced by incorporating sawdust, cork-dust, or wood pulp, a solution of magnesium chloride, magnesite, and French chalk, with or without colouring matter, and subsequently mixing with a solution of magnesium chloride in water until the desired plasticity is attained.—H. S. H.

Wood protection; Method of ——. P. Bartsch. U.S.P. 1,374,806, 12.4.21. Appl., 23.10.20.

Wood is protected from destructive organisms by removing the resin by means of a solvent, displacing the solvent by a chemical which in turn is displaced by an aqueous solution of arsenic and copper, then chemically dehydrating the wood to cause precipi-

tation of poisonous substances, displacing the dehydrant by a paraffin solvent, and finally displacing the latter by poisoned paraffin.—H. S. H.

Asphalt substitute. G.P. 332,888. *See* III.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Electrolytic iron [; Hardness on quenching of ——]. O. Bauer and W. Schneider. Stahl u. Eisen, 1921, **41**, 647—648.

Test-pieces of electrolytic iron, previously annealed at 950° C. and cooled in air, were quenched from different temperatures varying from 650° to 1200° C. The Brinell hardness showed little variation as did also the ultimate breaking stress. Similar results were obtained with iron annealed at 950° C. *in vacuo* and quenched at temperatures varying from 620° to 1100° C. The different results recorded by Boynton (J., 1906, 538) are probably due to the different methods employed for determining hardness.—J. W. D.

Copper in molybdenum ores; Behaviour of ——. J. P. Bonardi and M. Shapiro. Chem. and Met. Eng., 1921, **24**, 847—850.

Molybdenum interferes in the usual iodometric copper assay as it also liberates iodine from potassium iodide. Previous precipitation of the copper by zinc or aluminium is incomplete in the presence of molybdenum, but the latter may be removed by prolonged boiling of the solution with caustic soda. Double precipitation is, however, necessary to eliminate all the molybdenum, and the following modification of the thiocyanate method is, therefore, recommended. 0·5—5·0 g of finely powdered ore is dissolved in 10—15 c.c. of nitric acid, 5—10 c.c. of hydrochloric acid is added, the mixture evaporated nearly to dryness, the mass treated with a little water, 10—15 c.c. of dilute sulphuric acid (1:1) added, and the whole evaporated till fumes appear. The mass is cooled, treated with water, and the solution filtered. The filtrate is diluted to 250 c.c., treated with ammonia till just alkaline, then with 2 c.c. of sulphuric acid (1:1) and 2—3 g. of anhydrous sodium sulphite. To the boiling solution is then added 10—25 c.c. of a 20% ammonium thiocyanate solution, and the resulting copper precipitate is filtered off and washed till free from the blue colour of the reduced molybdenum compounds. It is redissolved in nitric acid, the solution evaporated nearly to dryness, and the assay finished by the iodide method as usual. Alternatively, the precipitate of cuprous thiocyanate may be extracted with hot caustic soda, the cuprous hydroxide filtered off, and the filtrate acidified and titrated with permanganate. In this case a weighed amount of pure copper should be put through the whole process as a standard. The separation of copper minerals from those containing molybdenum is briefly discussed.—A. R. P.

Tin in cassiterite; Determination of ——. H. Corti. Anal. Asoc. Quím. Argentina, 1921, **9**, 44—53.

The method proposed is a modification of that of Fresenius. Half a gram of the powdered material is mixed with 5 g. of a mixture of sodium carbonate and sulphur and placed in a crucible, in the bottom of which is about 2 g. of sodium carbonate. A covering of the sodium carbonate-sulphur mixture is added and the crucible placed in a cold muffle furnace. The muffle is heated to redness and maintained thereat for 2 hrs. After cooling, the melt is extracted with water and the residue washed with weak ammonium sulphide. Filtrate and washings are united and stannic sulphide is precipitated by adding 25 c.c. of hydrochloric acid (1:4). The stannic sulphide is collected on a filter and washed with 1% hydrochloric acid. It is then dissolved in strong hydrochloric acid with gentle boiling, the last traces of hydrogen sulphide being removed by the addition of a few drops of bromine. Ammonia is added till the reaction is alkaline and the liquid raised to boiling. The precipitate of hydrated stannic oxide is washed by decantation, using 1% ammonium nitrate containing a little ammonia, collected, dried, ignited, and weighed as stannic oxide.—G. W. R.

Bismuth [; Determination of ——] in high-grade ores. G. Spurge. Chem. Age, 1921, **4**, 584.

The following colorimetric method is recommended as giving in 15 mins. results correct to 0·2—0·3% in ores containing up to 45% Bi. 0·05 g. of finely powdered ore is dissolved in 100 c.c. of nitric acid (1:3) and the solution diluted to 500 c.c. A portion is filtered through a dry paper and transferred to a 25 c.c. burette, while a second burette contains a standard solution of bismuth (1 c.c. = 0·00005 g. Bi). Two Nessler tubes are prepared, each containing 10 c.c. of a 10% potassium iodide solution and 3 drops of a solution of sulphur dioxide. 1 c.c. of the bismuth standard solution is added to one tube and the assay is run into the other until the colours match. Lead and copper in large quantities are the only interfering metals. The former is removed by addition of sulphuric acid before making up to bulk and the latter by filtering off any precipitated iodide before comparing the colours, or by precipitating the bismuth as basic nitrate prior to making up to bulk.—A. R. P.

Patents.

Steel; Process of making ——. E. T. Pelton. U.S.P. 1,376,160, 26.4.21. Appl., 6.7.20.

A charge of iron materials low in phosphorus and sulphur is melted in an acid-lined furnace, and the slag is removed from the surface of the molten metal, which is then treated with a quantity of iron ore. Ebullition is produced in the mixture and the charge poured.—A. R. P.

Gases derived from roasting ores; Removal of dust from ——. Manufactures de Prod. Chim. du Nord, Etablissements Kuhlmann. E.P. 147,020, 6.7.20. Conv., 6.5.14.

In a dust-settling chamber the gas stream is caused to meet a series of chain curtains. The curtains are formed of a number of parallel single chains, each of which is arranged in relation to the adjacent ones so as to divide the gas stream as finely as possible. The separate chains may be connected together by a wire which affords a means of shaking the curtains and causing the collected dust to fall. —C. A. K.

Slags containing iron; Process of separating —— from coke and other fuel residues. F. Krupp A.-G. Grusonwerk. E.P. 152,642, 23.8.20. Conv., 11.10.19. Addn. to 150,333.

Particles of coke remain attached to the iron after the magnetic separation of slags containing iron as described in the chief patent (J., 1921, 139 A). The magnetic material is therefore ground and subjected to a second magnetic treatment.—C. A. K.

Ores; Treatment of argentiferous lead-zinc sulphide ——. F. E. Elmore. E.P. 162,026, 18.12.19.

Finely ground ore or concentrate is mixed with alkali or alkaline-earth chlorides, with or without the addition of zinc chloride, and heated to 450°—500° C. in an oxidising atmosphere. Lead together with a proportion of the silver is obtained in solution by extracting the oxidised mixture with hot brine,

and may be recovered by cooling the liquor. From the zinc sulphide which remains unattacked the remaining portion of the silver may be extracted by treatment with suitable solvents. (See also E.P. 129,773, 135,968, and 141,044; J., 1919, 685 A; 1920, 117 A.)—C. A. K.

Zinc solutions; Purification of ——. S. Field, and The Metals Extraction Corp., Ltd. E.P. 162,030, 19.12.19.

Zinc sulphate solutions acidulated, and at a temperature of 70°—100° C., are treated with either finely divided zinc or aluminium or an aluminium-zinc alloy in the form of powder or granules, in the presence of mercuric sulphate. These metals are more electro-positive than the metallic impurities present and cause the latter to be precipitated upon the mercury in the form of a sludge.—J. W. D.

Electro-deposition of metals upon iron and alloys of iron [; Cleaning process preliminary to ——]. R. J. Fletcher. E.P. 162,391, 28.1.20.

The iron or iron alloy is cleaned by being used alternately as cathode and anode in an acid bath containing copper sulphate, a current density of 150—500 amps. per sq. ft. being employed.
—J. S. G. T.

Aluminium alloys. T. F. Bradbury, and Rolls-Royce, Ltd. E.P. 162,467, 25.2.20.

Aluminium alloys containing 3—15% Cu, or 5—20% Zn, or 1—20% Zn and 1—6% Cu, show an increased fluidity when molten and reduced tendency to crack during solidification, and give sounder castings. Antimony, magnesium, and titanium may be added between the total limits of 0·5 and 3%, the higher limits of the individual metals being 1·5% Sb or Mg and 0·8% Ti.—C. A. K.

Alloys; Method of treating light-metal ——. W. R. Veazey, Assr. to Dow Chemical Co. U.S.P. 1,374,968, 19.4.21. Appl., 21.1.20.

Alloys of high magnesium content are heated to 500°—700° F. (260°—370° C.) and then forged or similarly worked.—J. W. D.

(A) *Acid-resisting alloy.* (B, C) *Alloy.* A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. (A) 1,375,081, (B) 1,375,082, and (C) 1,375,083, 19.4.21. Appl., (A) 27.7.18, (B, C) 15.8.18.

(A) An acid-resting alloy contains approximately 40% Cr and a metal having the properties of molybdenum, together with iron and carbon. (B) The principal components are molybdenum and a metal possessing the properties of nickel and cobalt, together with not more than 4% Mn. (C) Iron not exceeding 10% in quantity replaces the manganese in (B).—C. A. K.

Acid-resisting alloy. Acid-resisting article and method of making same. A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. (A) 1,375,672 and (B) 1,375,673, 26.4.21. Appl., 26.7.17.

(A) An alloy of 60% Cr, 2—4% Si, 2—5% C as graphite, and the remainder iron. (B) Articles made of iron-chromium alloys free from carbon are made acid-resisting by treating the surfaces in a suitable manner with carbon and then cooling rapidly, whereby iron and chromium carbides are produced in the surface layer.—A. R. P.

Alloys; Electrical-resistance ——. F. F. Hansen, Assr. to Hansen-Halliburton Mfg. Co. U.S.P. (A) 1,375,454 and (B) 1,375,455, 19.4.21. Appl., 19.9.19.

(A) An alloy containing approximately equal amounts of chromium and copper and not less than 10% of tungsten and molybdenum together, the tungsten being in excess of the molybdenum. (B) An alloy of chromium, tungsten, and aluminium, the chromium being in preponderating amount compared with the combined amount of tungsten and aluminium, and the tungsten being in excess of the aluminium.—J. W. D.

Alloy. C. D. Stovall. U.S.P. 1,375,804, 26.4.21. Appl., 14.7.20.

An alloy containing Au 72 pts., Ni 13¼ pts., and Cu 16¾ pts.—C. A. K.

Metal alloy. J. F. Wandersee, R. Peretto, and T. A. L. Albrecht, Assrs. to Ford Motor Co. U.S.P. (A) 1,376,056 and (B) 1,376,062, 26.4.21. Appl., 10.9.19 and 7.6.20.

(A) The alloy consists of 2—5% C, 35—65% Co, and the remainder chromium and tungsten. (B) An alloy of 20—35% Cr, 5—20% W, 1—15% Fe, and the remainder cobalt and carbon.—A. R. P.

Ores; Treatment [chloridising] of ——. J. H. Hirt, Assr. to Alvarado Mining and Milling Co. U.S.P. 1,375,002, 19.4.21. Appl., 24.1.20.

Ores, metallurgical products, and the like are chloridised by heating in a closed multiple-hearth furnace and then introducing a chloridising agent in a gaseous or vapour form.—A. R. P.

Ores; Separation of mixed sulphide ——. C. Faul and H. Lavers, Assrs. to Minerals Separation North American Corp. U.S.P. 1,375,087, 19.4.21. Appl., 12.3.15.

A mixed sulphide ore is concentrated selectively by means of a froth flotation process in presence of a copper material and an alkali bichromate.
—C. A. K.

Ore concentration process. W. A. Scott, Assr. to Minerals Separation, North American Corp. U.S.P. 1,375,233, 19.4.21. Appl., 10.9.17. Renewed 15.9.20.

A gas is introduced into the ore pulp in the form of minute bubbles, the resulting mineral-carrying bubbles are treated to remove the gas from them before they reach the surface of the pulp, and the mineral carried by the bubbles is separated from the remainder of the ore.—A. R. P.

Sodium; Manufacture of metallic ——. A. W. Smith and W. R. Veazey. U.S.P. 1,375,330, 19.4.21. Appl., 16.7.17.

A fused mixture of sodium carbonate and another salt is electrolysed, the ingredients being proportioned so that the mixture has a lower melting point than any of its constituents.—J. W. D.

Metallurgical furnace. D. Baird, Assr. to General Chemical Co. U.S.P. 1,375,346, 19.4.21. Appl., 17.6.20.

A multiple-hearth roasting furnace is provided with means for causing the material to fall from one hearth to another, and with an air conduit situated behind the stream of falling ore, so that an air blast may be directed into the stream.—A. R. P.

Furnace; Metallurgical ——. J. W. Griswold and H. O. Loebell. U.S.P. 1,375,754, 26.4.21. Appl., 24.7.18.

A closed melting chamber is surrounded by a number of combustion channels in which a mixture of gas and air is burnt. Products of combustion are passed through a detached heat exchanger, and the furnace is mounted on trunnions for pouring.
—C. A. K.

Converters; Gas-discharge conduit for rotary ——. W. H. Howard, Assr. to American Smelting and Refining Co. U.S.P. 1,375,965, 26.4.21. Appl., 4.12.19.

THE waste gas discharge flue from the upper side of a horizontal cylindrical matte converter is brought to a position concentrically disposed to the axis of the converter by means of right-angled bends. A loose sleeve connecting the discharge end portion with the flue leading to the chimney permits of rotation of the converter.—C. A. K.

[Mineral] values; Process for the extraction of —— from highly dilute solutions. M. L. E. Baudin. U.S.P. 1,375,441, 19.4.21. Appl., 7.4.17.

MINERAL compounds are extracted from very dilute solutions by bringing the latter into contact with a support coated with a colloidal absorbent material. —A. R. P.

Silver-solder. W. B. Bocchetti. U.S.P. 1,375,552, 19.4.21. Appl., 10.2.20.

A SOLDER containing Ag 55—65%, Cu 20—30%, Zn 10—20%, and arsenic trioxide.—J. W. D.

Brass scrap; Process of treating ——. O. C. Ralston. U.S.P. 1,375,930, 26.4.21. Appl., 2.1.20.

THE copper content of copper-bearing alloys is increased by treatment of the alloy with an aqueous solution containing a solvent for metals electro-positive to copper.—C. A. K.

Bearing metal. J. G. Kelly, A. L. Pringle, and H. Hall. U.S.P. 1,376,339, 26.4.21. Appl., 7.5.20.

THE alloy consists of 1 pt. of aluminium, slightly more than 1 pt. of zinc, 2 pts. of lead, and 4 pts. of tin.—A. R. P.

Ores or concentrates; Process of roasting ——. P. R. Middleton, Assr. to J. C. Lalor. U.S.P. 1,376,025, 26.4.21. Appl., 20.1.20.

ORE containing a metallic sulphide is heated in presence of air to a temperature below the ignition point of the sulphur, and maintained at this temperature until the maximum proportion of the metallic sulphide has been oxidised to sulphate. —W. J. W.

XI.—ELECTRO-CHEMISTRY.

Fuel cells; Construction of high-temperature ——. E. Baur, W. D. Treadwell, and G. Trümpler. Z. Elektrochem., 1921, 27, 199—208.

IN a former paper, fuel cells were described in which copper oxide was used as a cathode (J., 1916, 1266). A number of cells of varying construction have now been devised in which iron oxide is substituted for copper oxide. The cells described are of two types, carbon-oxygen and hydrogen-oxygen, and are all characterised by the use of a porous diaphragm in the form of a tube or crucible of magnesia, or better, of a specially-prepared magnesia-clay mixture suitably moulded and fired. One of the most satisfactory cells described had electrodes respectively of iron and magnetite packed in two channelled magnesia-composition tubes, air being passed through the Fe_3O_4 tube and hydrogen through the iron tube. The electrolyte, equal parts of fused caustic soda and potash, was contained in an iron vessel, and the surface of the electrolyte was covered with a considerable thickness of loose magnesia, in which the electrode tubes were embedded in a horizontal position. The porosity of the magnesia and of the tubes was sufficient to allow the electrolyte to make good contact with the electrodes. Such a cell gave an E.M.F. at 800° C. of 0·90 volt, and had an internal resistance of about 3 ohms. The opinion is expressed that such fuel cells are a technical possibility.—E. H. R.

Sodium-oxygen cell. E. Baur. Z. Elektrochem., 1921, 27, 194—199.

A METHOD has been devised for measuring directly the sodium-oxygen potential in a caustic soda cell at temperatures between 300° and 600° C. A number of different types of electrode were first tested by measuring the hydrogen-oxygen potential in caustic soda between 300° and 400° C. Measurements of the sodium-oxygen potential were eventually made in three types of cell, viz., with an alloy of sodium and lead containing 40 mols. % Na against a silver-oxygen electrode, with pure sodium against the same oxygen electrode, and with pure sodium against an iron-oxygen electrode. The lead-sodium alloy gave results about 0·3 volt lower than pure sodium. The cells containing pure sodium gave a mean result of 2·2 volts at 340° C., which corresponds with the value found by Neumann and Bergve for the decomposition potential of sodium hydroxide (J., 1915, 1088). The temperature coefficient found was, however, smaller than theirs, namely, $-1·3\times10^{-3}$ instead of $-2·95\times10^{-3}$. Some experiments were also made on the behaviour of the cells when supplying current. As the current increases, polarisation sets in, but may be partly prevented by increasing the rate of the oxygen current.—E. H. R.

PATENTS.

Melting and other furnaces; [Packing for] electrically heated ——. The Morgan Crucible Co., and C. W. Speirs. E.P. 162,246, 7.10.19.

IN using electrically heated crucibles etc. of the type described in E.P. 24,626 of 1912 (J., 1913, 1019), mounted in a metal or other casing from which they are insulated by refractory brick, access of air to the carbon resistors is avoided by using natural crystalline plumbago of a "platey" nature as a packing between the resistor and the refractory wall of the furnace. A layer of fine powder, such as sand, is placed at the bottom of the annular space between the resistor and the refractory wall.—J. S. G. T.

Electric furnace. W. K. Booth and W. L. Morris, Assrs. to The Booth Electric Furnace Co. U.S.P. 1,376,072, 26.4.21. Appl., 9.4.20.

AN electric furnace having a refractory lining is provided with means for rotation about its axis. Electrodes, extending axially through the end walls of the furnace, are carried by adjustable supports mounted on the end walls and are provided with metal collars through which water may be circulated during rotation of the furnace.—J. S. G. T.

Electrolytic cell. H. I. Allen and K. R. Fox, Assrs. to Electron Chemical Co. U.S.P. 1,374,976, 19.4.21. Appl., 1.6.20.

AN anode for use in the electrolysis of saline solutions consists of one or more flat carbon plates provided with spaced parallel ribs, the faces of the ribs and of the plates between the ribs being active.
—J. S. G. T.

Battery electrode; Depolarising —— and process of making same. R. C. Benner and H. F. French, Assrs. to National Carbon Co. U.S.P. 1,375,647, 19.4.21. Appl., 22.8.18.

CUPROUS oxide prepared electrolytically is oxidised to cupric oxide and then mixed with sulphur.
—J. S. G. T.

Electrically preparing stencil plates, die plates and the like; Solution or bath for ——. G. E. Wertheimer. U.S.P. (A) 1,376,366, (B) 1,376,367, (C) 1,376,368, and (D) 1,376,369, 26.4.21. Appl., (A) 24.12.17, (B, C, D) 16.5.18.

A SOLUTION for the electrolytic treatment of metallic plates or blocks is composed of an aqueous solution of sulphuric acid and nitric acid together with (A) ammonium chloride, (B) ammonium chloride with a small proportion of copper nitrate, (C) ammonium chloride with a small proportion of acetic acid, (D) small proportions of iodine, copper nitrate, and acetic acid.—J. S. G. T.

See also pages (A) 421, *Electrical gas purification* (E.P. 145,477). 426, *Liquid fuel* (U.S.P. 1,376,180). 432, *Perborates* (U.S.P. 1,375,596); *Arsine, phosphine, and stibine* (U.S.P. 1,375,819). 434, *Quartz glass* (U.S.P. 1,375,657). 436, *Electrodeposition* (E.P. 162,391); *Electrical-resistance alloys* (U.S.P. 1,375,454—5).

XII.—FATS; OILS; WAXES.

Herring oil. T. Lexow. Chem. Umschau, 1921, 28, 85—86, 110—113.

THE following constituents are well established:—Myristic, palmitic, zoomaric, stearic, oleic, clupanodonic, gadoleic, and erucic acids, together with acids of formulæ $C_{20}H_{30}O_2$ and $C_{22}H_{34}O_2$, hydroxylated acids, and unsaponifiable matter. Oil from salted herrings also contains lactones, lipoids, and soaps. Formation of free fatty acids begins the moment the herring is dead; the quantity in ordinary good quality oil lies between 2 and 5%. The colour and flavour show no close relationship to the free fatty acid content, the former depending largely on the fishes' nourishment and the method of pickling. The author finds the saponification value unaffected by the season of the year or the size of the fish. There is, however, a considerable variation of this value according to the latitude in which the fish are caught, average values rising from 184 to 189 with an increase in latitude from 66° to 71°. The percentage of unsaponifiable matter varies in a similar way, but inversely with increase in latitude. About 120 determinations of the iodine value (Wijs) show that this varies markedly with the season of the year, in the same way as the yield of oil—the two latter figures being at their highest (149 and 13%) in July, August, and September and at their lowest (110 and 2%) in March.—H. C. R.

Critical temperatures of solution of fats in mixtures of ethyl and amyl alcohols. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1921, 30, 14—16, 58—62.

EXPERIMENTS were undertaken to determine whether a mixture of 94% ethyl alcohol with isoamyl alcohol (*cf.* J., 1914, 1074), which gave critical solution temperatures similar to those of Crismer's ethyl alcohol, could advantageously replace the latter. A mixture which gave with light petroleum the same CST as Crismer's alcohol was found to give lower values with glycerides, and a mixture which gave with beef fat the same CST as Crismer's alcohol, gave, especially with cacao butter and light petroleum, higher values than those of Crismer's alcohol. The distances between the extreme critical solution temperatures of the substances examined are greater for Crismer's alcohol than for the amyl alcohol mixtures, which gives the former a greater sensitiveness. The divergences observed with the amyl alcohol mixtures seem to be due to the relative solubility of the fats in amyl alcohol.—G. F. M.

Sulp[on]ated oils; Improved formulæ for the calculation of inorganic impurities in ——. R. Hart. J. Amer. Leather Chem. Assoc., 1921, 16, 159—161. (*Cf.* J., 1921, 226 A.)

THE formula previously cited may be simplified when 2A is equal to or $<A_S$ since no carbonate can be present.

Inorganic impurities $=$ Ash $- 0{\cdot}0634(2A+A_S)$.

When $2A>A_S$ sodium carbonate will be found in the ash. By substituting A_S for 2A in the sulphate term the formula becomes

Inorganic impurities $=$ Ash $- (0{\cdot}0795A_S+0{\cdot}0946A)$.

These new formulæ are simplified by substituting S (the percent. combined SO_3) for its equivalent A_S. They become in the absence of carbonate

Inorganic impurities $=$ Ash $- 0{\cdot}1268(7S+A)$,

and where carbonate is present

Inorganic impurities $=$ Ash $- 0{\cdot}0946(11{\cdot}77S+A)$.

The data required are:—ash, combined SO_3 (S), and fixed alkalinity (A) in mg. of KOH.—D. W.

Oxidation of vaseline and paraffin. Langen. *See* IIA.

PATENTS.

Oils and fats; Refining of ——. V. Schwarzkopf. E.P. 138,115, 22.1.20. Conv., 25.10.18.

THE oil is mixed with 4—8% of bleaching earth, *e.g.*, fuller's earth, and heated *in vacuo* to 250° C. in a current of hydrogen until free fatty acids no longer distil over.—H. C. R.

Hydrogenation of unsaturated oils and fats; Process for the continuous ——. E. R. Bolton. E.P. 162,370, 26.1.20.

THE oil is hydrogenated in vessels fairly tightly packed with nickel wool which has been activated by treatment with nitric acid, roasting, and reducing in a current of hydrogen. The activity of the catalyst may be restored *in situ* by washing with hot oil to remove soaps, then with an oil solvent, and finally re-heating in hydrogen.—H. C. R.

Hydrogenation of oils, fats, and the like; Method of maintaining the activity of metallic catalysts during the ——. E. R. Bolton and E. J. Lush. E.P. 162,382, 27.1.20.

THE poisoning of the nickel catalyst by soap formation is avoided by the addition of a small quantity of mono- or diglycerides of fatty acids to the oil to be treated. This combines with any free fatty acids present or formed during hydrogenation and so prevents the attack of the nickel. Oils contain-

ing free fatty acids can be hydrogenated directly after adding enough mono- or diglycerides to combine with the free fatty acids.—H. C. R.

Oils, fats, and fatty acids; Process of extracting ——. R. H. McKee. U.S.P. 1,376,211, 26.4.21. Appl., 24.5.19.

The material containing oil is dehydrated and subjected to the solvent action of liquid sulphur dioxide.—B. M. V.

Fat; Stimulating the production of —— in microbes. Reichsausschuss für pflanzl. und tier. Oele und Fette, G.m.b.H. G.P. 332,411, 12.10.18.

The microbes are exposed in the form of a thin layer to the action of air containing alcohols or their derivatives, *e.g.*, air mixed with the gases derived from fermentation processes.—L. A. C.

Fats and oils; Process for neutralisation [and hydrogenation] of ——. H. Schlinck & Co. G.P. 334,659, 15.8.16. Addn. to 315,222 (J., 1920, 198 A).

Neutralisation and hydrogenation are effected simultaneously by adding glycol and a suitable catalyst to the fat or oil and then treating it, at a high temperature, with hydrogen, preferably in excess.—J. H. L.

Catalytic agents for reduction or hydrogenation purposes; Process for producing ——. A. Radisson (Assr. to Soc. de Stearinerie et Savonnerie de Lyon), and P. Berthon. U.S.P. 1,377,158, 3.5.21. Appl., 29.10.19.

See E.P. 107,004 of 1917; J., 1918, 431 A.

Decolorising charcoal. E.P. 162,117. *See* IIb.

Products soluble in or forming emulsions with water. E.P. 134,223. *See* III.

Vulcanised-oil product. U.S.P. 1,376,172—4. *See* XIV.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colophony; New constituents of ——, *colophenic acids and their analogues.* O. Aschan. Ber., 1921, 45, 867—886.

A new series of acids, $C_nH_{2n-10}O_4$, has been isolated from the residues left after the preparation of pinabietic acid from the "black liquor" of sulphate-cellulose factories (J., 1919, 646 A) and also from American and Finnish colophony. These are provisionally termed colophenic acids. They are monobasic acids which are differentiated from the resin acids by the ready solubility of their sodium salts in cold water and the stability of the solutions towards carbon dioxide. The lactone ring and the aldehydic group are not present. The presence of the ketonic group could not be definitely established but one oxygen atom is present in a hydroxyl group. The acids are colourless or pale yellow, whereas solutions of their alkali salts are dark yellow or brownish-yellow. Hexadekacolophenic acid, $C_{16}H_{22}O_4$, m.p 96°—105° C. (yellow granules, from concentrated solution) or 86°—98° C. (almost colourless powder, from dilute solution), $[\alpha]_D^{17} = +22.33°$ (colourless form) or $+21.66°$ (yellow form) in benzene solution, heptadekacolophenic acid, m.p. 100°—105° C. after softening at 70°—75° C., oktodekacolophenic acid, and eikosicolophenic acid, which softens at 80°—90° C. and is molten below 110° C. are described. Hexadekacolophenic acid is prepared artificially by the oxidation of a slightly alkaline solution of pinabietic acid with hydrogen peroxide. (*Cf.* J.C.S., July.)—H. W.

Resin of maritime pine; Acid constituents of the ——. G. Dupont. Comptes rend., 1921, 172, 1184—1186. (*Cf.* J., 1921, 357 A.)

Pimaric acid as isolated from pine resin and purified by Vesterberg's method (*cf.* J., 1906, 82) consists of a mixture of 37% of *d*-pimaric acid and 63% of *l*-pimaric acid.—W. G.

Patents.

Paint vehicle. Paint composition. Paint vehicle for anhydrous pigments. Paint composition. W. N. Blakeman, jun. U.S.P. (A) 1,375,352, (B) 1,375,353, (C) 1,375,354, and (D) 1,375,355, 19.4.21. Appl., 12.6.17.

A mixture of (A) hydrogenated oil, tung oil, and marine animal oil or (C) untreated commercial marine animal oil and tung oil is used as a paint vehicle. As a paint composition (D) a mixture of an anhydrous pigment with the vehicle described under (C), or (B) an anhydrous mixture of pigment with a fluid hydrogenated oil may be used.
—D. F. T.

Resinous condensation products [from hydrogenated naphthalene]; Manufacture of ——. A.-G. für Anilin-Fabr. G.P. 305,575, 19.4.17.

Hydrogenated naphthalene is treated with formaldehyde in the presence of acids, with or without the addition of a solvent or diluent. The products can be worked up with turpentine and linseed oil for the manufacture of varnishes.—L. A. C.

Wood; Process for impregnating —— before painting. H. Haarhaus and W. Hoffmann. G.P. 332,908, 3.3.20.

To accelerate the drying of oil paints when applied to wood, the latter is first impregnated with a neutral or slightly alkaline solution of alkali naphthenates, and then treated with salts of iron, aluminium, zinc, lead, manganese, or cobalt, to cause precipitation of metallic naphthenates.
—W. J. W.

Asphalt substitute. G.P. 332,888. *See* III.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Patents.

Vulcanising processes and apparatus for the manufacture of high pressure expanded vulcanised rubber and like substances. C. L. Marshall. E.P. 162,176, 15.4.20

For the manufacture of a semi-rigid expanded vulcanised rubber, ceresin wax or similar material is incorporated into the mixture so as to render it capable of retaining an inert gas under pressure. By enclosing the material before vulcanisation in a skin of rubber which will allow the diffusion of gas, the vulcanised foam is protected against subsequent mechanical disruption. Vulcanisation is effected in an externally heated chamber containing a removable inner chamber which is provided with inlet and outlet valves for the automatic control of the internal gaseous pressure transmitted from the compressed atmosphere of the larger vessel. The froth formation is developed by a rapid partial reduction of pressure at the completion of vulcanisation, whilst the rubber is still hot.—D. F. T.

Vulcanisation of caoutchouc; Process for the ——. S. J. Peachey. E.P. 162,429, 12.2.20. Addn. to 129,826 (J., 1919, 688 A).

In the vulcanisation of rubber by the action of hydrogen sulphide and sulphur dioxide, the process is accelerated by applying one or both of the gases under pressure.—D. F. T.

Vulcanised rubber goods; Methods for the preservation of ——. H. P. Stevens. E.P. 162,528, 16.4.20.

THE rate of perishing of vulcanised rubber decreases with the proportion of moisture in the surrounding atmosphere. For the preservation of rubber goods, therefore, the atmosphere of the storage chamber is kept saturated with moisture, or nearly so. (*Cf.* J., 1920, 251 T.)—D. F. T.

Vulcanised-oil product. W. O. Snelling. U.S.P. (A) 1,376,172, (B) 1,376,173, and (C) 1,376,174, 26.4.21. Appl., (A, B) 8.8.19 and (C) 21.8.19.

(A) A VULCANISED oil product is depolymerised in the presence of hydrogen chloride. (B) Various degrees of plasticity are imparted to different portions of vulcanised oil, and the products are mixed. (C) A liquid vulcanised oil product capable of being solidified by contact with water is claimed. (*Cf.* U.S.P. 1,315,246 of 1919; J., 1920, 697 A.)
—D. F. T.

Rubber; Drying —— *by means of indifferent gases.* A.-G. Metzeler und Co. G.P. 332,974, 21.2.19.

FLUE gases freed from ashes, soot, sulphur dioxide, etc., and cooled or heated as the case may be, are employed.—J. H. L.

Rubber-like products; Hindering oxidation in synthetic ——. Badische Anilin- und Soda-Fabr. G.P. 332,305, 28.3.18. Addn. to 330,741 (J., 1921, 312 A).

THE material is mixed with aromatic nitro-compounds, *e.g.*, 1% of nitronaphthalene, nitrobenzene, etc., instead of phenols or naphthols. The products can be vulcanised as usual.—J. H. L.

Rubber-like products; Preparation of ——. Badische Anilin- und Soda-Fabr. G.P. 333,496, 22.8.18. Addn. to 329,676 (J., 1921, 400 A).

THE polymerisation is carried out in presence of aromatic hydroxy- or nitro-compounds, or other substances which hinder oxidation of synthetic rubber-like products (*cf.* preceding abstract). The added substances remain homogeneously distributed throughout the products and minimise oxidation during the working of the latter.
—J. H. L.

Rubber products; Manufacture of ——. Goodyear Tire and Rubber Co., Assees. of C. W. Bedford. E.P. 146,992, 6.7.20. Conv., 29.5.17.

SEE U.S.P. 1,323,951 of 1919; J., 1920, 123 A.

Vulcanising; Method and apparatus [*annular moulds heated by induced electric currents*] *for* ——. Goodyear Tire and Rubber Co., Assees. of C. W. Post. E.P. 145,425, 17.6.20. Conv., 22.5.19.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning material; Yield of extract from ——. A. Harvey. J. Soc. Leather Trades' Chem., 1921, 5, 115—117.

IN calculating the yield of extract from tanning materials an error is usually made by ignoring the decrease in weight sustained by the material due to loss of soluble matter. This loss, which may run as high as 20%, is only partly accounted for by the formation of sludge during cooling. In a case now being investigated a very considerable loss was sustained, although very little sludge was formed.
—D. W.

Tanning solutions; Filtration of ——. J. G. Parker and J. T. Terrell. J. Soc. Leather Trades' Chem., 1921, 5, 112—115.

EXPERIMENTS are described showing the superiority of the Berkefeld filter candle to filter paper for the determination of soluble matter in tanning extracts. There is loss of soluble matter due to adsorption by the filter paper even when a considerable quantity (200 c.c.) of the filtrate is rejected before evaporating to dryness. Differences of 3·5% and 5·1% of total soluble matter were obtained with mimosa and quebracho extracts respectively. Filter candles are now obtainable, and their use should be made compulsory.—D. W.

Tannins; Action of —— *and the swelling of pelt.* G. Grasser. Collegium, 1921, 1—10, 58—67, 105—117. (*Cf.* J., 1921, 154 A.)

TANNINS have very little repressing action on acid-swollen pelt. Neither sodium chloride nor gallic acid exerts any swelling action on pelt. Formaldehyde has an extraordinarily high repressing action on acid-swollen pelt and neither acids nor alkalis can modify it. Formaldehyde is the most astringent tanning agent known. From their action on swollen pelt, phenol and phenolsulphonic acids should prove good bating materials. Vegetable tannins do not reduce acid-swollen pelt, but the effect is different if the pelt is treated with tannin first and then with acid. Pieces of pelt were treated with different tannin solutions and then with acid and the increase in weight determined and compared with the increase in weight obtained by subjecting untreated pelt to the same acid treatment. From the figures obtained, the initial speed of tannage, C, was calculated. The maximum speed of tannage, J, was similarly obtained by making experiments over longer periods of time, and the intensity of tannage, E, was calculated by dividing the maximum speed of tannage by the time to attain that maximum. Tables are appended giving C, J, and E for a large variety of tanning materials. A comparison of these figures shows that there are tannins which have a comparatively high initial tanning velocity, C, but it is not maintained to the end of the tannage. The synthetic tannins are characteristic in this respect. They have the highest C value and are specially suitable for re-tanning. Tannins which resemble dyes (mangrove, cutch, and logwood) have a very low initial tanning velocity and intensity in spite of their ready solubility. This is due to their feeble tanning properties. Sulphite-cellulose, though a weak tanning agent, has a high tanning velocity. The more favourable behaviour of basic chromic sulphate in comparison with basic ferric sulphate explains why chrome tannage has become of such practical importance. Potash alum gives low values. True tannins do not give high values for C, J and E, but an average for J, 0·45—0·58, C, 0·40—0·49 and E, 0·40—0·54. The values observed for various materials, including tannins and others, are J, 0·36—0·97, C, 0·36—0·93, and E, 0·32—5·62.
—D. W.

Hydrolysis and adsorption [*by hide*]. V. Kubelka. Collegium, 1921, 135—141.

A CRITICISM of Moeller's work (J., 1920, 730 A).
—D. W.

Syntheic tannins. C. Immerheiser. Collegium, 1921, 130—132.

A CRITICISM of Moeller's views on synthetic tannins (J., 1921, 154 A). Sulphonation is not the essential principle involved in the preparation of synthetic tannins, but only a means of rendering some of them soluble, and β-naphthalenesulphonic acid, which has none of the characteristics of a tannin, cannot be compared with commercial synthetic

tannins which have a definite tanning action. Ordoval has no harmful action on leather even when used in excess. The synthetic tannins are valuable because of their easy penetrability, and because they dissolve difficultly soluble tannins in mixture with vegetable tanning materials. Ordoval, for dissolving solid quebracho extracts, has replaced sulphiting. In spite of all attacks, the synthetic tannins have gained a firm footing in the leather trade and have attained to great practical importance.—D. W.

Chrome [tanning] liquors; Acid titration of ——. A. W. Thomas and S. B. Foster. J. Amer. Leather Chem. Assoc., 1921, 16, 61—63.

Dhavale and Das (J., 1920, 758 A) have shown that the maximum increase in acidity is obtained by adding 49 g. or more of sodium chloride to 400 c.c. of solution containing 0·1747 g. of chromium. With samples of chrome liquors diluted to 400 c.c. with distilled water and treated with 50 g. of sodium chloride, the amount of acid found by titrating the boiling solution with $N/10$ alkali was equal to that determined by the conductance method. The official method for titrating chrome liquors can be made to yield more correct results by adding 50 g. of sodium chloride to the solution before the titration is commenced.—D. W.

Chrome tanning; One-bath ——. E. Griliches. Collegium, 1921, 127—129. (*Cf.* J., 1920, 633 A.)

In reply to Stiasny's criticisms (J., 1921, 53 A) the author states that he used feebly pickled pelt for his experiments, equivalent to 2 c.c. of $N/10$ NaOH per litre, which would be insufficient to influence the figures as Stiasny suggests. It is not easy to show the influence of the acid content of the pelt on the acid taken up from the tanning liquor, and it is probable that Stiasny greatly over-estimates that influence. In Stiasny's suggested method of expressing the basicity of chrome liquors $Cr:SO_4=52{\cdot}1:X$, the author considers that X should be termed the acidity.—D. W.

Aldehyde tannage. VII. W. Moeller. Collegium, 1921, 117—125.

Aldehyde tannage is differentiated from all other kinds of tannage both qualitatively and quantitatively. The peculiar structure of the hide and the energetic tanning action of formaldehyde prevent pelt from absorbing much formaldehyde. Freiberg hide powder has been treated with formaldehyde and all experiments done with it in determining the tanning action of formaldehyde are influenced thereby. Using stronger solutions of formaldehyde and very finely divided untreated hide powder, it is possible to get as much as 27% of formaldehyde taken up by the hide powder, which is almost the same as the amount absorbed by animal charcoal. Pieces of pelt treated with formaldehyde solutions of similar strength do not take up more than 4% of formaldehyde owing to their microscopic structure. The formaldehyde polymers choke the pores of the leather and prevent further penetration.—D. W.

Iron tannage. D. D. Jackson and T. P. Hou. J. Amer. Leather Chem. Assoc., 1921, 16, 63—75, 139—159, 202—219, 229—259.

Iron is more basic than either chromium or aluminium. Ferric salts, particularly the sulphate, are very readily hydrolysed, and the ferric hydroxide thus formed seems to pass through the colloidal range so rapidly that it is soon precipitated and this causes hard and brittle leather. Another difficulty with iron tannage is that the ferrous iron in solution, though easily partially oxidised, is completely oxidised only with difficulty. It is necessary to convert the ferrous iron to the ferric state completely and then to keep it in the ferric state throughout the tanning operation under adverse conditions, and to prevent the separation of any hydrated ferric oxide by maintaining the proper acidity of the liquor employed. Chlorine, sodium nitrate and sulphuric acid, nitric and sulphuric acids, and sodium bichromate are the most suitable oxidising agents, and working details are given for their use in the manufacture of iron tanning liquors. Ferric chloride is more stable towards dilution than ferric sulphate for the same basicity and behaves like chromic chloride and other chromic salts. The oxidation of ferrous sulphate by chlorine is a ready means of securing one-third of acid radical in the form of a chloride. $Fe(OH)SO_4$ is very unstable whilst more basic ferric chlorides are quite stable. On treating pelt with basic iron liquors, the iron is absorbed by the skin very rapidly. The mineral acid is also taken up by the skin but in less proportion. The tannage is complete after drumming for 1½ hrs. Iron seems to yield a more permanent tannage than alum but the leather will not withstand the action of boiling water. An iron-tanned leather, properly tanned, is not brittle on the grain and does not deteriorate on storing. It is important to rinse the tanned stock, after neutralisation, to remove soluble salts. The harsh feel, due probably to the presence of a large amount of iron oxide in the leather, may be counteracted somewhat by heavy fat-liquoring, oiling, or the use of flour. Not less than 4% Fe_2O_3 should be present in the air-dried leather. Iron-tanned leather compares favourably with other mineral-tanned leathers but the colour is an undesirable feature for some purposes. The basicity ratio of the tanning liquor should vary between one OH equivalent to every 3—5 equivalents of mineral acid radical. The neutralisation should be gradual so that the iron may be uniformly fixed throughout the whole skin. Before dyeing, the leather should be dried out to minimise the chemical reactions between the iron in the skins and the substances employed. A procedure for the chemical analysis of iron-tanned leather is outlined, including the following determinations:—moisture, fat, ash, Fe_2O_3, Cr_2O_3, free mineral acid, P_2O_5, total SO_3, hide substance.
—D. W.

[Tannin analysis;] Shake method and the filter bell process [of ——*].* G. Baldracco and S. Camilla. Collegium, 1921, 125—127. (*Cf.* J., 1920, 496 A.)

A reply to Lauffmann's criticism of the authors' modified shake method (Collegium, 1920, 430).
—D. W.

Free sulphuric acid in leather and animal hide; Determination and behaviour of ——. C. Immerheiser. Collegium, 1921, 132—135. (*Cf.* J., 1920, 731 A.)

Moeller's criticisms of the determination of free sulphuric acid in leather by the ether-sulphuric acid method (J., 1921, 53 A) are not based on experimental evidence. His claim that leather may contain a considerable amount of chloride is not borne out in practice even with mangrove-tanned leathers, and his assertion that organic matter combines with the sulphuric acid and causes a lower figure to be obtained than the actual amount of acid present is not supported by facts. The amount of sulphuric acid purposely added to a leather can be determined by this method with a fair degree of accuracy. When pelt is brought into contact with a tanning material which has an acid reaction, a process of neutralisation ensues, and this fact can be established experimentally. With increasing tannage the acid figure of the leather diminishes until a constant is obtained which is characteristic for each tannin. The "acid figure" of the finished leather is apparently dependent on the acidity of

the tanning material, so that a leather tanned with a strongly acid tannin will require less acid to neutralise it than a leather tanned with a less acid tannin.—D. W.

Chrome alum solutions. Meunier. *See* VII.

Sulphonated oils. Hart. *See* XII.

2.4.6-*Trinitroresorcinol.* Einbeck and Jablonski. *See* XX.

PATENTS.

Tanning substances; Manufacture of artificial ——. M. Melamid. E.P. 137,323, 2.1.20. Conv., 24.12.18.

THE alkali-soluble portion of anthracene oil or "soft pitch" is treated with aromatic sulphochlorides in alkaline solution, and the product is sulphonated.—D. W.

Tanning substances; Process for the manufacture of artificial ——. M. Melamid. E.P. (A) 148,268, 23.2.20, and (B) 148,738, 25.2.20. Conv., (A) 19.7.19 and (B) 21.7.19. Addn. to 137,323 (*cf. supra*).

(A) The alkali-soluble portion of anthracene oil boiling between 100° and 300° C. (12 mm.), or of soft pitch (100 kg.), is sulphonated at 30°—40° C. with an equal weight of 100% sulphuric acid until the mass is soluble in water, when the product is dissolved in water, neutralised with sodium hydroxide, and the bulk of the sodium sulphate removed by evaporation and crystallisation. A solution of 28 kg. of sodium hydroxide is added to the product, and the mixture is agitated with a solution of 100—110 kg. of *o*- and/or *p*-toluenesulphonyl chloride in 200 l. of benzene at normal temperature until the whole of the sulphonyl chloride has entered into reaction. The product is used for tanning without further treatment. (B) The product as obtained above, but omitting the treatment with sulphonyl chlorides, is used direct for tanning.—L. A. C.

Substances precipitating glue [tanning agents]; Manufacture of ——. A. Römer, Assr. to A. Kuttroff. U.S.P. 1,375,976, 26.4.21. Appl., 9.5.17. Renewed 29.6.20.

A NAPHTHALENESULPHONE is sulphonated and the product is treated with formaldehyde, yielding a substance capable of precipitating glue from its solutions.—L. A. C.

Leather; Process for impregnating and loading ——. H. Burger. G.P. 303,204, 15.5.14.

THE addition of naphthalene, alone or in combination with substances such as fat, paraffin, tallow, wax, resin, asphalt, or caoutchouc, to impregnating or filling agents for leather, improves their penetrating power. Sulphur may be utilised as an impregnating agent by dissolving it in naphthalene. The dried, heated leather is steeped in the solution at 100° C. for ½—1 min. The product may be readily dyed.—W. J. W.

Hides; Depilation of ——. W. Rautenstrauch. G.P. 304,251, 8.4.17.

BARIUM hydroxide solution, of a concentration above $N/10$, forms a satisfactory depilatory agent for hides. The waste solution may be used again after addition of more barium hydroxide, and its efficiency is not affected by presence of albuminoid matter from the hides. After treatment the hides may be freed from barium hydroxide by washing with water containing a small amount of sulphuric, hydrochloric, lactic, or butyric acid, or of an acid salt.—W. J. W.

Hides; Process for unhairing —— *by the action of enzymes.* R. Hilgermann and M. Emmerich. G.P. 334,526, 26.10.18.

CULTURES of *B. emycoides tumescens, megatherium*, and *mesentericus* are prepared using a mixture of beef, horse-flesh, eggs, and lactose, and of *Mucor* and *Aspergillus* using yeast, glucose, resin, and asparagin, whilst mixed cultures are prepared by means of glycerin and peptone. By suitable treatment enzyme preparations are obtained from these bacteria and moulds in 8—12 weeks. The hides, which have been previously softened with acid and alkali, are placed in water and treated with the enzyme preparation, in the proportion of 300—500 c.c. per 100 kg. of hide, for 24—96 hrs. at 22°—25° C. —W. J. W.

Substances precipitating glue [tanning agents]; Manufacture of ——. A. Römer, Assr. to A. Kuttroff. U.S.P. 1,375,975, 26.4.21. Appl., 28.11.14. Renewed 24.4.20.

SEE G.P. 293,042 of 1913; J., 1916, 1072.

Casein specially adapted for the production of imitation horn; Manufacture of ——. A. Bartels. E.P. 162,301, 16.1.17.

SEE U.S.P. 1,320,666 of 1919; J., 1919, 955 A.

XVI.—SOILS; FERTILISERS.

Soil organic matter and organic carbon; Dry combustion method for the simultaneous determination of ——. J. W. Read. J. Ind. Eng. Chem., 1921, 13, 305—307.

A WEIGHED portion of the soil is digested with dilute hydrochloric acid and hydrofluoric acid to remove carbonates and hydrated minerals, and the insoluble portion is collected on a layer of asbestos in a combustion boat having a perforated bottom (*cf.* Rather, J., 1918, 478 A). After drying, the boat is transferred to a silica combustion tube which is heated by a three-unit electric furnace; the tube is packed as follows:—oxidised copper gauze, combustion boat, asbestos and pumice coated with cerium dioxide, copper oxide, asbestos and pumice coated with cerium dioxide, and copper gauze filled with lead peroxide. The latter layer is maintained at 300°—320° C. The carbon dioxide is absorbed in bulbs filled with soda-lime.—W. P. S.

Humic acids. S. Odén. Kolloid-Chem. Beih., 1921, 11, 75—260.

A COMPREHENSIVE review of the humic acids. These acids are subdivided into humic acid, hymatomelanic acid and fulvic acid. Humic acid with ammonia yields salts and adsorption compounds. Humic acid has an equivalent of 340 ± 10; it is tetrabasic, insoluble in water, but readily forms colloidal solutions. It has the composition $C_{60}H_{52}O_{24}(CO_2H)_4$ and the anion is almost black in colour. Hymatomelanic acid is yellowish-brown and has an equivalent weight of 200; its salts are insoluble in alcohol, but easily form highly dispersed suspensions. Humus colloids exert a protecting action on clays which is of the same order as that of other protective colloids, but is specific to certain varieties of clay and electrolytes. Limed samples of humoid soil bind more water than unlimed samples, but the difference in amount is not of practical importance. The limed humus gives up its water more readily than the unlimed humus. After liming the water appears to be a little more firmly held and consequently is less easily taken up by plants.—J. F. S.

Boron in relation to the fertiliser industry. J. E. Breckenridge. J. Ind. Eng. Chem., 1921, 13, 324—325.

During recent years potash has been obtained from many new sources and some of the raw materials used have contained boron; cases of injury to crops have been noticed where such fertilisers have been used. Maize and beans are injured by the application of 6 lb. of borax per acre; the growth of potatoes appears to be stimulated with 4—6 lb. of borax per acre, but with 10 lb. there is decrease in root formation. With plenty of moisture the plants recover gradually, but would probably die in a dry season.—W. P. S.

Sulphur; Non-biological oxidation of elementary —— in quartz media. W. H. MacIntire, F. J. Gray, and W. M. Shaw. J. Ind. Eng. Chem., 1921, 13, 310—313.

Sulphur is oxidised by moist quartz under sterile and non-sterile aërobic and anaërobic conditions. The oxidation is accelerated by the presence of limonite and is decreased by that of iron or magnesium carbonate.—W. P. S.

Cellulosic residue of leaves. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1920, 29, 317-322.

The insoluble cellulose residue (residue remaining after an acid and alkali treatment of the dried and powdered substance) of various leaves, including the vine, lilac, gooseberry, raspberry, and lime, at various periods of growth, was determined. Very irregular variations were found at different periods, and in different years, for the same kind of leaf, and no general relationships were apparent similar to those previously found for the ash, water or starch content at different stages of development of the leaf. The acid residue and the alkaline residue of the dried leaf showed analogous variations.

Fertilisers; Manufacture of ——. Badische Anilin u. Soda Fabrik. E.P. (A) 145,036 and (B) 145,037, 14.6.20. Conv., 29.7.16 and 26.3.17.

(A) A non-deliquescent and non-explosive fertiliser is obtained by mixing ammonium nitrate and potassium chloride in the presence of a small quantity of water, or by mixing ammonium nitrate, containing a small percentage of moisture, with dry potassium chloride. Crude potassium chloride containing about 64% KCl may be used. (B) Ammonium nitrate in the dry state is mixed with potassium chloride or potassium sulphate in absence of water.—W. J. W.

Fertiliser, and process for making same. E. H. Sams. E.P. 161,777, 17.2.20.

Unground chalk is mixed with house refuse which has been pulverised and screened, or with the ashes of the same, and the mixture is then milled. The addition of the house refuse facilitates the grinding of the chalk owing to absorption of its moisture.
—W. J. W.

Fertiliser; Process of producing ——. M. Shoeld, Assr. to Armour Fertilizer Works. U.S.P. 1,375,115, 19.4.21. Appl., 13.9.20.

A suitable material is added to wet precipitated phosphate to prevent the latter becoming dusty after drying.—W. J. W.

Lime; Production of catalytic —— for fertilising. R. Mandelbaum. G.P. 333,484, 22.12.18.

The fertilising properties of lime are improved by the addition of small amounts of calcium sulphate, sulphite, or sulphide. By the action of water on calcium sulphate and sulphide in the soil, heat is generated.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Decomposition of —— during milling. J. N. S. Williams. Int. Sugar J., 1921, 23, 271—272.

It is believed that an appreciable loss of sucrose must occur during the operation of milling under present-day conditions, that is, when the cane is finely shredded, and when the filter-press wash-waters and the thin juices from the last unit are used for maceration. It was observed in the case of Plantation A, applying a moderate crushing and maceration, that the extraction was 89·1%, the fibre content, 13·3, the polarisation of the first mill juice, 16·6, the purity of the first mill juice, 88·3, and the calculated sugar in the cane, 279·4 lb. per ton; while on Plantation B, in which the cane was subjected to the extreme degree of crushing and compound maceration, the extraction was 96·34, the fibre content, 13·76, the polarisation of the first mill juice, 17·5, the purity of the first mill juice, 87·55, and the calculated sugar in the cane, 268·2 lb. per ton. Thus, Plantation A dealing with an inferior cane showed 279·4 lb. of sugar per ton of cane compared with 268·2 lb. in the case of Plantation B with a much better cane.—J. P. O.

Sucrose; Neutral polarisation modification of the Clerget method of determining ——. C. A. Browne. Int. Sugar J., 1921, 23, 276—281.

Replying to Jackson and Gillis (J., 1921, 361 A), the author agrees that in the case of Method 2 prescribed in Bull. 375 (J., 1920, 634 A) the errors in determining the positive and negative constituents do to a considerable extent neutralise each other, though his experiments show that compensation is perfect only at a concentration of about 13 g. of sucrose per 100 c.c. However, he points out that in the case of Method 3 (*loc. cit.*) for the analysis of beet products, the errors remain uncompensated, since the ammonium chloride is present only when making the negative reading, none being added for the positive reading as in Method 2. In Method 3, therefore, the final error may be considerable.
—J. P. O.

Sucrose; Determination of —— by the inversion method. V. Sázavsky. Z. Zuckerind. Czechoslov., 1921, 45, 227—229, 235—238.

is completely precipitated by basic lead acetate and For the clarification of solutions of raw (beet) sugar products the author recommends tannin solution followed by basic lead acetate solution. Although commercial tannin is optically active it gives rise to no error. A solution containing the normal weight (26 g.) of molasses may be treated with 10—15 c.c. of a 6% tannin solution and then, after shaking round, with 10—12 c.c. of basic lead acetate solution; for twice the normal weight of raw sugar it is usually sufficient to employ 10—20 drops of the tannin solution, followed by 1—2 c.c. of basic lead acetate. Solutions thus treated require no further clarification after inversion. Determinations of the inversion constant under Clerget-Herzfeld conditions, for different concentrations of pure sucrose, practically confirmed Herzfeld's formula. The presence of 1 g. of molasses ash in the solution raised the constant by 0·2; and in inverting 6·5 g. of molasses it is therefore better to

employ the factor 132·66 than the lower one corresponding to 6·5% solution of pure sucrose. For the inversion of molasses 5 c.c. of acid is not always sufficient, and it is advisable to use 6·5 c.c. Stanek's method for eliminating the error due to optically active non-sugars (J., 1914, 705) is considered more convenient than those proposed by Saillard and Andrlik and Stanek (*cf.* J., 1911, 63).—J. H. L.

Dry substance of sugar products; Determination of —— by means of the refractometer in the presence of crystals. H. Kalshoven. Archief Suikerind. Nederl.-Indië, 1920, **28**, 913—917. Int. Sugar J., 1921, **23**, 289—290.

In determining the dry substance of sugar products containing crystals, the author no longer uses the lower prism of the refractometer, the massecuite or molasses being pressed with the aid of a small glass plate (reinforced with a piece of copper sheet) against the upper prism, and the reading taken at least 10 mins. after turning on the cooling water. —J. P. O.

Sugars; Configuration of some ——. [Use of invert sugar in titrating boric acid.] J. Böeseken and H. Couvert. Rec. Trav. Chim., 1921, **40**, 354—380.

The electrical conductivity and optical rotation, with and without the addition of boric acid, of a number of substances of the sugar group have been determined. Invert sugar, prepared by heating sucrose for 1 hr. at 100° C., with 0·25 times its weight of 0·1% aqueous hydrochloric acid and neutralising the product, may with advantage be employed in titrating boric acid with barium hydroxide. Very accurate results are obtained in $N/10$ solution with phenolphthalein as indicator if sufficient invert sugar be used to provide 5 mols. of lævulose for every mol. of boric acid. (*Cf.* J.C.S., July.)—C. K. I.

Starch; Studies on ——. A. Reychler. Bull. Soc. Chim. Belg., 1920, **29**, 309—317.

The gelatinisation of starch can be conveniently followed microscopically at ordinary temperatures by using a solution containing about 0·135 mol. of alkali hydroxide per litre. A similar action is produced by $4N$ or $5N$ acids and by certain concentrated salt solutions, such as 30% ammonium nitrate, 15% potassium thiocyanate, etc. The reverse action is produced if to 100 c.c. of a starch paste, 80 g. of sodium sulphate, 40 g. of ammonium or magnesium sulphate, etc., is added, a complete coagulation resulting in a few minutes regardless of the temperature. Under ordinary conditions this retrogradation takes 10 or 12 days, and is then only partial. The microscopical observations may be interpreted by postulating that the starch mucilage is a suspension of swollen and partially burst granules consisting of an internal substance and an envelope which is impenetrable by water unless at an elevated temperature or in presence of an alkali, etc., when it becomes hydrated and allows the internal material to form a voluminous gel or sol. The coagulum produced by sodium sulphate etc., is composed of amorphous granules, smaller in size than the swollen granules of the mucilage, and formed by the shrinking of the envelope and the consequent expulsion and coagulation of the internal sol. Starch solutions formed by heating the mucilage at 120°—150° C. exhibit a similar phenomenon of coagulation, and the precipitate formed may readily be isolated by taking advantage of its resistance to diastase. On drying it forms a hard, warty mass, resistant to all reagents except potash, but still showing under the microscope its constituent globules. It is dissolved by water at 150° C., and the solutions resemble those of the original starch, but are characterised by giving a deeper blue colour with iodine, and by yielding an almost theoretical quantity of maltose when treated with malt extract. It appears, therefore, to be composed exclusively of a polysaccharide (amylose), whilst the original starch contains in addition a more refractory substance originally designated by Maquenne amylopectin (*cf.* J., 1905, 630). Amylose may therefore be characterised as a solid, relatively soluble, in the starch granules; colloidally dissolved and coagulable in the internal fluid of the granules in the mucilage, in starch solutions, and in solutions of the coagulum; solid and attackable with difficulty in the coagulum. Amylopectin is met with as a solid, dense and resistant in the envelope of the starch granules; as solid, but swollen permeable by water and liquefiable by malt extract, in the granular envelopes of the mucilage; and also dissolved in the starch solutions. —G. F. M.

XVIII.—FERMENTATION INDUSTRIES.

Extract yield from raw grain (maize and rice); Determination of ——. W. Windisch and P. Kolbach. Woch. Brau., 1921, **38**, 57—59, 63—64, 76—77.

A comparative study of various methods. In the one recommended 40 g. of the maize or rice is mixed with 150 c.c. of water and 100 c.c. of a filtered malt extract (made by digesting 1 pt. of malt with 4 pts. of water for 1 hr. at 30° C. with frequent stirring). Next morning the mash is heated rapidly to 70° C., then in 40 mins. to 80°, and then boiled for 5 mins. on a sand-bath. After cooling to 50° it is treated with a further 100 c.c. of malt extract and the temperature is maintained at 50° for ½ hr., raised to 70° in 20 mins., maintained at 70° for 25 mins., raised to 75° in 5 mins., and maintained at 75° for 30 mins. The cooled mash is made up to 450 g. before filtering. The method of calculation is explained fully.—J. H. L.

Malt analysis; Comparative experiments respecting the most convenient method of calculation and the accuracy attainable in the pyknometric determination of extract in ——. H. Keil. Woch. Brau., 1921, **38**, 95—96.

In accurate determinations of wort gravities by the pyknometer, tedious corrections for air displacement under different conditions of barometric pressure may be avoided by the use of a "compensation pyknometer" (*i.e.*, a counterpoise such as a pyknometer suitably loaded with shot and hermetically sealed, having approximately the same weight and volume as the pyknometers in use when the latter are filled with water). The exact weight of the counterpoise is determined once for all, and the extra weights required in one pan or the other to balance a pyknometer filled with water or wort against the counterpoise are added to or subtracted from the weight of the latter. This method has been adopted in the analytical laboratory of the Versuchs und Lehranstalt in Berlin.—J. H. L.

Enzymes; Actions between ——. H. Van Laer. Bull. Soc. Chim. Belg., 1919, **28**, 340—346.

The maceration juice, separated at the moment of autolysis from a mixture of dried yeast and water, contains an invertase, which is sensitive to both active and passive papaïn and to amylase. This sensitiveness is not shown by the juice separated after autolysis or by the limpid extracts from yeast killed by acetone. The liquids obtained by macerating yeast killed by acetone with active solutions of papaïn or amylase show a notable increase in inverting power, which is apparently due to the difference between the increase resulting from the liberation of invertase masked by the protoplasmic substances, and the diminution caused by a greater sensitiveness of the freshly liberated enzyme to the products of digestion of its cellular substrate.
—W. G.

Fruit wine; Preparation of —— from frozen or frost-bitten fruit, with special reference to changes in the juice corresponding to the severity of freezing. A. Widmer. Schweiz. Apoth.-Zeit., 1920, **58**, 339—344. Chem. Zentr., 1921, **92**, II., 878—879.

Expressed juice from frost-bitten fruit (apples and pears) has a low sp. gr. owing to its relatively large amount. Mere freezing of the fruit produces no perceptible change in the constituents of the juice, and does not preclude vinification provided the fruit is thawed without delay, at the lowest possible temperature, and the expressed juice is fermented at once. In frost-bitten fruit, on the other hand, there occurs a decrease in the acidity and tannin-content of the juice, part of the tannin being precipitated in combination with proteins; such fruit yields mild but unstable juices which sometimes have an unpleasant flavour and odour. Frost-bitten unripe fruit is only fit for vinification if free from the last-mentioned defects, and in any case it is advisable to employ pure yeast for the fermentation. All fruit wine made from frozen fruit should be consumed as soon as possible.—J. H. L.

Patents.

Alcoholic fermentation; Process for accelerating ——. Aktiebolaget Astra, Apotekarnes kemiska fabriker. G.P. 334,866, 7.5.14. Conv., 6.5.13.

The liquid to be fermented is treated with one or more salts of organic acids, other than ammonium salts, or with neutralised solutions containing organic acids produced biochemically. Alkali salts of acids of the formic and glycollic acid series are particularly active, producing an acceleration of 30—100%, with increased attenuation in many cases.—J. H. L.

Fat in microbes. G.P. 332,411. *See* XII.

Extracting ferments etc. G.P. 334,660. *See* XX.

XIXa.—FOODS.

Milk; Detection of the addition of sodium carbonate to ——. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1920, **29**, 52—54.

The author relies on an ash analysis. The ash of milk normally contains Na 6·0%, K 20·4%, P_2O_5 26·3%. The addition of sodium carbonate will alter the ratio of Na+K to P_2O_5 as well as the ratio Na to K.—W. G.

Goat's milk; Detection of —— in cow's milk. W. Austen. Milchw. Zentr., 1921, **50**, 125—127.

The method depends on the insolubility of the casein of goat's milk in 25% ammonia, in which the casein of cow's milk is completely soluble. It is only applicable to fresh milk. Potassium bichromate should be used as a preservative, as formaldehyde affects the solubility of the casein. The cream should first be separated as completely as possible by centrifuging in a Gerber tube stoppered at both ends, and removing by means of a fine pipette. About 20 c.c. of the separated milk is thoroughly mixed with 2 c.c. of 25% ammonia in the Gerber tube and heated in a water bath for about ½ hr. The tube is then placed in a centrifuge with the graduated part outwards and rotated at about 1200 revs. for some minutes. Cow's milk gives little or no precipitate, whereas that from pure goat's milk about half fills the narrow graduated tube. Less than 20% of goat's milk in cow's milk can, however, not be detected with certainty. The method can be applied to approximate quantitative estimations.
—H. C. R.

Lard; Boehmer's method for detecting tallow in ——. Vitoux and C. F. Muttelet. Ann. Falsif., 1921, **14**, 86—92.

Further experiments with the method previously described (J., 1921, 126 a) confirm its usefulness. As little as 5% of beef or mutton fat can be detected in lard, the value (2G − A) falling below 68; even in the case of lard adulterated with beef or mutton fat together with fats rich in liquid glycerides, *e.g.*, horse fat, the method loses none of its sensitiveness. It is equally effective in detecting hydrogenated fish oils. Fats poor in solid glycerides, however, such as oleomargarines and horse tallow, escape detection unless present to the extent of more than 20—30%, but it appears possible that a modification of the method may overcome this difficulty.—J. H. L.

Phytase; Activity of —— as determined by the specific conductivity of phytin-phytase solutions. F. A. Collatz and C. H. Bailey. J. Ind. Eng. Chem., 1921, **13**, 317—318.

Changes in the specific conductivity of an aqueous solution of phytin and phytase indicate the progress of the hydrolysis of the phytin. In the case of phytase prepared from wheat bran, the most favourable temperature for complete hydrolysis appears to be about 55° C., although the hydrolysis proceeds more rapidly at 60° C. during the first 15 mins.
—W. P. S.

Wheat flour grades. Electrical conductivity of water extract. C. H. Bailey and F. A. Collatz. J. Ind. Eng. Chem., 1921, **13**, 319—321.

The specific conductivity of water extracts of wheat flour varies with the time and temperature of extraction; the highest values are obtained at about 60° C., and the conductivity is due chiefly to inorganic phosphates resulting from the hydrolysis of phytin by phytase. To compare different flours it is necessary to use a uniform procedure in the preparation of the extracts, and it is suggested that 10 g. of flour be heated at 25° C. for 30 mins. with 100 c.c. of conductivity water, the mixture then centrifuged, and the conductivity of the clear extract determined at 30° C. with a dip electrode. The specific conductivity of flour extracts runs parallel with the ash content and can be used as an index of the grade of the flour.—W. P. S.

Patents.

Cooked food products from wheat grain; Manufacture of ——, and apparatus therefor. C. V. Rowell. E.P. 140,457, 18.3.20. Conv., 18.3.19.

Whole wheat grains are heated at about 460°—

500° C. for about ½ min. in presence of highly superheated steam under a pressure of about 1000 lb. per sq. in., and the product is ejected from the horizontal, cylindrical heating chamber by a sudden release of the pressure.—H. H.

Blood-meal; Manufacture of ——. G. A. Krause. G.P. 332,434, 19.8.17.

Blood which has coagulated without heating, and in which the clots have been subsequently broken up into fine particles, is atomised and dried by a current of hot air, yielding a meal completely soluble in water with the exception of the fibrin. —L. A. C.

Plants; Process for improving the flavour and odour of food- or fodder-yielding —— *of the Cruciferæ or related families.* H. Brün. G.P. 334,274, 18.10.17.

The comminuted and partially or completely dried material is moistened with a very dilute solution of hydrogen peroxide, then tightly compressed for 48 hrs., and afterwards spread out and dried. Products thus obtained from beets and the like may be used as diluents or substitutes for flour or soup powders or may be employed in the manufacture of jam.—J. H. L.

Pickling brine; Process for recovering proteins contained in ——. G. Coblitz. G.P. 334,322, 10.12.16.

The proteins, separated from solution by fractional thermal coagulation, are cooled at once by means of water or otherwise, and the different fractions are subsequently mixed and dried as usual.—J. H. L.

Lupin seeds, horse chestnuts and the like; Removal of bitter substances from ——. P. Schmidt. G.P. 334,589, 5.12.18.

The seeds, freed from shells, are treated for 1 hr. at 95°—100° C. with a dilute solution (1:25) of the waste mother liquor from potash manufacture, and then twice more with similar solution, for 2 hrs., each time at 50° C., with continuous stirring, and finally the seeds are well washed with water, dried, and ground if necessary.—J. H. L.

Fodder from straw (e.g., from cereals or leguminous plants); Preparation of a —— *by digestion of the comminuted material [with alkali solution].* Veredelungsges. für Nahrungs- und Füttermittel m.b.H. G.P. 335,155, 27.3.18. Addn. to 305,641 (J., 1919, 789 A).

The alkaline digestion liquors are used over and over again until they become acid, and each charge of straw is digested in stages with successive portions of liquor, each fresher than the preceding one. The alkali is thus completely utilised and digestion is accelerated.—J. H. L.

Cooling chocolate and other materials; Machine for ——. E. Savy. U.S.P. 1,375,734, 26.4.21. Appl., 1.3.19.

See E.P. 124,196 of 1919; J., 1920, 78 A.

XIXb.—WATER PURIFICATION; SANITATION.

Boiler feed water; Purification of ——. F. Blumenthal. Z. angew. Chem., 1921, **34**, 189—192.

A review of the lime-soda, baryta, Permutite, and Neckar processes for softening boiler feed water. The lime-soda process can only reduce the hardness to a limit of 2 or 3 degrees on account of the solubility of calcium and magnesium carbonates, and in addition soluble sodium salts and about 10—15 g. of sodium hydroxide per cub. m. are left in the water and pass into the boilers, which must therefore be blown out periodically. In the baryta and Permutite processes, on the other hand, smaller amounts of soluble salts are left in the feed water. In the Neckar process, heating the feed water to 80° C. cannot cause the precipitation of the calcium and magnesium carbonates; such precipitation must be due solely to the soda alkalinity of the boiler water which is returned to the purifier. Moreover, the statement that in this process the carbonic acid is entirely precipitated is quite incorrect, since it is all converted in the purifier into sodium bicarbonate, is fed into the boiler, and is there expelled with the steam, the residual normal carbonate being returned to the purifier and the above operation repeated. Magnesium salts are only completely precipitated when sufficient sodium hydroxide is formed in the boiler by hydrolysis of the carbonate unless additional hydroxide is supplied to the purifier, which materially increases the cost of the process.—G. F. M.

Cryptogamic diseases of plants; Use of coloured screens for combating ——. R. Lance. Comptes rend., 1921, **172**, 1201.

The spray is prepared by mixing 650 g. of ultramarine blue, 250 g. of ultramarine green, and 100 g. of ultramarine violet with several litres of water, adding 2 kg. of calcium sulphate and 1350—1400 g. of quicklime, and when the colouring is uniform, stirring in 1 kg. of aluminium sulphate or 1·5 kg. of alum. The precipitated alumina fixes the dye and the whole mixture is diluted to 400 litres and is ready for use. The deposit formed on the plants by the use of this spray acts as a colour screen, permitting only blue, violet, and ultra-violet rays to pass.—W. G.

Anticryptogamic product. R. Lance. Comptes rend., 1921, **172**, 1201—1202.

The material recommended is prepared by dissolving 1 kg. of zinc sulphate in 100 l. of water, adding 500 g. of lime to precipitate the zinc as hydroxide, and then 80—100 g. of an ultramarine colour. Finally 250 g. of aluminium sulphate is added and the whole is well shaken and after filtering is ready for use. This mixture, it is claimed, combines the antiseptic action of zinc with the microbicidal action of the blue, violet, and ultra-violet rays. —W. G.

Patent.

Water; Process and apparatus for removing dissolved oxygen from ——. L. and C. Steinmüller. G.P. 334,181, 28.3.17.

The water is passed slowly over an extensive surface of iron in a direction substantially parallel to the surface. Vessels or drums packed with a series of concentric sheet iron cylinders may be used. The process is more effective than the use of filters containing iron shavings, and the apparatus lasts longer and is more easily cleaned than the latter. —J. H. L.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; Chemico-toxicological detection of ——. D. Ganassini. Boll. Chim. Farm., 1921, **60**, 2—5.

In the test for morphine given by Denigès (J., 1911, 47), the copper sulphate and hydrogen peroxide may be replaced by potassium ferricyanide and ammonia; the reaction is then applicable to the detection of morphine in blood and in non-putrefied animal organs, but is not very sensitive. The copper sulphate may be replaced also by hæmatin, which readily catalyses hydogen peroxide, the

hæmatin of human blood being far more active in this respect that that of the blood of animals. For the detection of morphine in blood, Denigès' test must be modified as follows: 0·25 c.c. of blood is diluted to 10 c.c. with water and the solution treated with nitric acid (about 10 drops) until a brown precipitate of globin and hæmatin is formed. The liquid is filtered and the colourless or almost colourless filtrate treated with 1 c.c. of ammoniacal cuprammonium sulphate solution, prepared by adding 10 drops of hydrogen peroxide solution (1 vol. perhydrol to 1 water) to a mixture of 20 c.c. of concentrated ammonia with 5 c.c. of 0·5% copper sulphate solution. With blood free from morphine, the liquid remains colourless, whereas the presence of a minute proportion of morphine rapidly produces a more or less intense pink coloration. This procedure serves also for the detection of morphine in milk or urine, addition of nitric acid being then unnecessary; in these cases, however, the reaction is less sensitive than with blood. The above reaction is given neither by hydroxydimorphine, nor by the alkaloids accompanying morphine in opium, nor by artificial derivatives of morphine such as dionine and peronine, but it is shown, contrary to the statement of Denigès, by heroine. The latter gives the following specific reactions, which serve to distinguish it from morphine: When heated with sulphuric acid it yields acetic acid, or in presence of alcohol, ethyl acetate; when treated with concentrated nitric acid it becomes successively yellow, greenish-blue, and yellow slowly in the cold, but rapidly when heated; when treated with 2 c.c. of a solution of urotropine (hexamethylenetetramine) in concentrated sulphuric acid it turns first golden-yellow, then orange, and finally dark blue.—T. H. P.

Iodotannic syrups; Preparation of ——. Rapid determination of combined iodine. T. Ugarte. Anal. Asoc. Quím. Argentina, 1921, **9**, 5—16.

Methods are described for avoiding loss of iodine in the preparation of iodotannic syrups. Two rapid methods are described for the estimation of combined iodine in two different types of preparation. The second method, which is applicable in both cases, consists in titrating the syrup with $N/10$ mercuric chloride until a permanent opalescence is obtained; each molecule of mercuric chloride corresponds to three atoms of combined iodine.
—G. W. R.

Humic acids; Synthetic and natural ——. W. Eller. Brennstoff-Chem., 1921, **2**, 129—133.

Humic acids have been obtained by the oxidation of phenols in alkaline solution (J., 1920, 717 A). The chemical reactions of the products resemble those of the natural humic acids. (*Cf.* J.C.S., July.)—W. P.

2.4.6-Trinitroresorcinol (styphnic acid). H. Einbeck and L. Jablonski. Ber., 1921, **54**, 1084—1089.

Styphnic acid, m.p. varying from 174° C. to 179°—180° C., is obtained by the oxidation of quebracho extract with nitric acid (sp. gr. 1·4). For its characterisation the mono- and di-potassium salts have been prepared by the regulated addition of alcoholic potassium acetate solution to styphnic acid dissolved in acohol, and the mono- and di-sodium salts by the use of alcoholic sodium hydroxide. All the salts, the mono-sodium compound in particular, explode violently when heated. (*Cf.* J.C.S., July.)—H. W.

Tartaric acid and acid potassium tartrate; Manufacture of ——. H. Voss. Chem.-Zeit., 1921, **45**, 309—313, 335—337, 360—364, 411—412.

The manufacture of acid potassium tartrate, with details of the necessary plant is described. An extensive survey of the manufacture of tartaric acid by both the neutral and the acid process has been made, for details of which the original paper should be consulted.—W. J. W.

ββ-Dichloroethyl sulphide. Delépine, Fleury, and Ville. Comptes rend., 1921, **172**, 1238—1240.

ββ-Dichloroethyl sulphide when prepared from ethylene and sulphur chloride is never pure. It contains substances which are apparently isomeric with it, and on distillation under reduced pressure yields a small amount of hydrogen chloride. It cannot be used satisfactorily as a solvent for cryoscopic measurements.—W. G.

Cyanic acid and urea; Synthesis of —— by oxidation of ketones, acids, and amines in presence of ammonia. R. Fosse and G. Laude. Comptes rend., 1921, **172**, 1240—1242.

Cyanic acid and subsequently urea, by tautomerisation, have been obtained by the oxidation in the presence of ammonia of ketones, mono- and dibasic acids, phenols, alcohols, and amines. The yield of urea varies considerably with the substance used, and in the case of amines, those capable of giving formaldehyde by oxidation give the highest yield.—W. G.

Chloroform; Manufacture of —— from ethyl alcohol, and the mechanism of the reaction. S. Ochi. Kogyo-Kwagaku Zasshi (J. Chem. Ind. Japan). 1921, **24**, 209—228.

Chloroform was prepared by passing chlorine into a mixture of ethyl alcohol and milk of lime at 60° C., the concentration of alcohol being 10%, and the quantity of calcium hydroxide ca. 300 g. per litre of alcohol, and that of chlorine 0·75—0·87 mol. per mol. of calcium hydroxide; 63·5—65·5% of the chlorine and 54·4—54·9% of the alcohol were utilised. Magnesium oxide, barium oxide, sodium and potassium hydroxides gave poorer yields than calcium oxide, and ferric hydroxide had no catalytic action on the process. The products of the reaction were examined quantitatively, and it is concluded that reactions corresponding to the following equations take place: $2C_2H_5OH+8CaOCl_2 = 2CHCl_3 + 2Ca(OH)_2 + 5CaCl_2 + Ca(HCO_2)_2 + 2H_2O$; $2C_2H_5OH+10CaOCl_2 = 2CHCl_3+2Ca(OH)_2+7CaOCl_2 + CaCO_3 + CO_2 + 3H_2O$; $C_2H_5OH + 2CaOCl_2 = CH_3COOH + 2CaCl_2 + H_2O$. 65—75% of the formic acid produced is decomposed into carbon dioxide and water by further oxidation and one-fourth of the acid remains unchanged in the residue. About two-thirds of the alcohol used is utilised in the formation of chloroform and the greater part of the remainder is converted into acetic acid. Carbon dioxide is not produced directly from the alcohol. The explosive reaction in manufacturing chloroform is due to violent evolution of oxygen by the decomposition of calcium hypochlorite at the high temperature produced during the oxidation of the alcohol. It can be avoided by operating at a lower temperature.—K. K.

Ethyl chloride; Rate of evaporation of —— from oils. C. Baskerville and M. Hirsh. J. Ind. Eng. Chem., 1921, **13**, 322—323.

The rate of evaporation of ethyl chloride from oils (maize oil) quickly acquires a definite and fairly constant velocity when the mixture contains 13—14% by vol. of ethyl chloride. If a mixture originally containing 15% is used, the uniform speed of evaporation is established within 10 mins. for surface exposures.—W. P. S.

Acetic acid and anhydride. L. Crismer and J. Timmermans. Bull. Soc. Chim. Belg., 1920, **29**, 46—52.

The rule of mixtures for critical temperatures of

solution does not apply to mixtures of acetic acid and its anhydride. By means of determinations of critical temperatures of solution with a Russian petroleum it is shown that phosphoric anhydride is a suitable reagent for dehydrating acetic acid.
—W. G.

Catalysts; Influencing of the activity of ——. III. Oxidative catalytic dehydrogenation of alcohols. I. K. W. Rosenmund and F. Zetzsche. Ber., 1921, **54**, 1092—1098. (*Cf.* J., 1921, 321 A, 368 A.)

THE catalytic oxidation of a primary alcohol may lead to the production of aldehyde, acid, ether, and condensation products. The reaction has been studied in the case of benzyl alcohol under conditions which do not involve vaporisation and with the object of limiting the scope of the change to the production of benzaldehyde. Benzyl alcohol only gives about a 3% yield of the latter when oxidised by oxygen in boiling cumene solution and this yield is not very greatly increased in the presence of copper, silver, magnesium, platinum, nickel, aluminium, zinc, antimony, or carbon. Amongst these almost equivalent catalysts, selective action can be induced in the cases of copper, nickel, and silver by the suitable addition of quinoline, the production of benzaldehyde being favoured in the case of copper and the formation of ether and condensation products in the cases of nickel and silver, thus giving an example of the transformation of slightly active catalysts into powerful and specific substances. The dehydrogenating action of catalytically excited oxygen and of nitro-groups is additive, the latter being introduced preferably in the form of *m*-dinitrobenzene. The best yields of aldehydes from alcohols are obtained by the oxidation of an equimolecular mixture of alcohol, quinoline, and *m*-dinitrobenzene in cumene solution in the presence of copper.—H. W.

Alcohols; Catalytic dehydrogenation of ——. E. K. Rideal. Proc. Roy. Soc., 1921, **A99**, 153—162.

IN confirmation of Sabatier's experiments the application of the Nernst approximation formula indicates that the variation of the dissociation constants of the equilibria, $CH_3CHO+H_2 \rightleftarrows C_2H_5OH$ and $CH_3COCH_3+H_2 \rightleftarrows CH_3.CH(OH).CH_3$, with the temperature are extremely large. The velocity of decomposition at the surface of a solid catalyst is much higher than the reverse reaction of hydrogenation. The variation of the values of the dissociation constants with the temperature was experimentally determined with a constant volume thermometer containing reduced copper as catalytic material, and at low pressures a fairly close approximation to reversibility was obtained. The value of ΔU_0 (heat of reaction) for the decomposition of ethyl alcohol was determined as 11,500 cals., whilst the mean value from the heats of combustion is 10,700. In the case of isopropyl alcohol the respective values are 21,300 and 11,800 cals., but an error of 1% in determining the heat of combustion of the alcohol would account for the discrepancy.
—G. F. M.

Verbenene (dehydro-α-pinene) and certain of its derivatives. A. Blumann and O. Zeitschel. Ber., 1921, **54**, 887—894.

CRUDE *l*-verbenene (J., 1913, 498) readily yields a crystalline dibromide, m.p. 70°—72° C., $[\alpha]_D^{15}=+297.65°$ in benzene solution, from which the parent substance is regenerated by reduction with zinc and acetic acid. Pure *l*-verbenene has sp. gr. 0·8866 at 15° C., $[\alpha]_D=-100.61°$, whilst the *d*-compound has sp. gr. 0·8867 at 15° C., $[\alpha]_D=+100.71°$, $n_D^{20}=1.49800$. The mode of formation, physical constants, and chemical behaviour of the compounds are in harmony with the view that verbenene is dehydro-α-pinene. Reduction with sodium and ethyl alcohol converts *l*-verbenene into dihydroverbenene (δ-pinene), b.p. 158°—159° C. at 762 mm., sp. gr. 0·865 at 15° C., 0·8625 at 20° C., $n_D^{20}=1.4662$, $[\alpha]_D=+36.52°$. (*Cf.* J.C.S., July.)—H. W.

Potassium oxalates. Sąbalitschka. *See* VII.

PATENTS.

Lobelia inflata; Process for obtaining the active ingredient of ——. C. H. Boehringer Sohn. E.P. 145,622, 29.6.20. Conv., 2.9.14. Addn. to 145,621 (J., 1921, 195 A).

THE active α-lobeline hydrochloride present in the aqueous solution after the crystallisation of the β-lobeline hydrochloride, can be extracted by other chlorinated solvents such as carbon tetrachloride, trichloroethylene, or tetrachloroethane, instead of chloroform.—D. F. T.

Butyl alcohol; Manufacture of secondary ——. C. Weizmann and D. A. Legg. E.P. 161,591, 24.2.16.

LIQUEFIED β-butylene is mixed with 75% sulphuric acid, with phosphoric acid, or with benzenesulphonic acid, either at ordinary temperatures under pressure, or at −10° to −15° C. under atmospheric pressure, and when the hydrocarbon has completely dissolved the liquid is distilled with steam, pure secondary butyl alcohol passing over.
—G. F. M.

[Hydr]oxyaldehydes and their derivatives; Manufacture of ——. G. B. Ellis. From Soc. Chim. des Usines du Rhône. E.P. 161,679, 13.1.20.

HYDROXYALDEHYDES are produced by the action of formaldehyde on a phenol or a phenol derivative in presence of a nitroso-compound, such as nitrosobenzene or nitrosodimethylaniline, and, if necessary, a catalyst. For example, vanillin is obtained by treating for 1—2 hrs. a solution, in 50 pts. of methyl alcohol, of 4 pts. of guaiacol, the nitrosodimethylaniline derived from 8 pts. of dimethylaniline, and 8 pts. of 40% formaldehyde, hydrogen chloride being continuously bubbled through. The product is diluted with water, the methyl alcohol distilled off, and the vanillin extracted from the aqueous residue with ether or benzene. The nitrosodimethylaniline is mostly transformed into *p*-aminodimethylaniline. (Reference is directed, in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Acts, 1907 and 1919, to E.P. 139,153; J., 1920, 527 A.)—G. F. M.

Oxalic acid; Manufacture of —— from carbohydrates. Valentiner u. Schwarz, G.m.b.H. G.P. 329,591, 20.12.13.

SUGAR (100 pts.) is treated below 70° C. with a mixture of, *e.g.*, 320 pts. of sulphuric acid, 300 pts. of nitric acid, and 380 pts. of water in the presence of salts of vanadium, molybdenum, or manganese, as catalysts, yielding 142 pts. of oxalic acid. The reaction is allowed to continue until the liquor is free from nitric acid, and the nitrous fumes evolved are absorbed by the mother liquor from a previous preparation.—L. A. C.

Alkyliminodisulphonic acids; Production of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 330,801, 4.8.18.

BASIC salts of iminodisulphonic acid react with organic halogen compounds, such as methyl iodide, epichlorhydrin, or ethylene bromide, or inorganic acid esters, such as dimethyl sulphate, in accordance with the equation, $KN(SO_3K)_2+R.Cl=KCl+R.N(SO_3K)_2$. The salts of alkyliminodisulphonic acids hydrolyse in the presence of acid in two stages, with the production first of alkyliminomonosulphonic acids and then of alkylamines. Potassium dihydroxypropyliminosulphonate,

$$(SO_3K)_2N.CH_2.CH(OH).CH_2.OH,$$

is prepared by the prolonged action of epichlorhydrin on an aqueous solution of potassium iminodisulphonate at normal temperature in the presence of potassium hydroxide and subsequent evaporation of the solution; the product is stable in neutral or alkaline solution, but is decomposed by boiling with acids into sulphuric acid and dihydroxypropylamine. The preparation of potassium ethylenediaminetetrasulphonate, and of potassium methylaminomonosulphate and methylamine from potassium methyliminodisulphonate, are also described.—L. A. C.

Alcohols and amino-alcohols of the quinoline series; Preparation of ——. Preparation of quinolyl ketones. Vereinigte Chininfabr. Zimmer und Co., G.m.b.H. G.P. (A) 330,813, 8.3.18, and (B) 330,945, 11.6.18. (B) Addn. to 268,830 (J., 1914, 277).

(A) QUINOLYL ketones and quinolyl aminoketones are reduced to secondary alcohols by treatment in alcoholic solution with a metal of which the hydroxide possesses weakly acid properties, such as zinc or aluminium, and with an alkali ethoxide. Quininone, $CH_3O.C_9H_5N.CO.C_9H_{14}N$, yields a mixture of quinine and quinidine; the former is isolated as the insoluble sulphate, and the latter is extracted with ether from the mother liquors after they have been made alkaline. Dihydrocinchoninone, $C_9H_6N.CO.C_9H_{16}N$, yields dihydrocinchonine and dihydrocinchonidine, both of which occur naturally together with quinine, and also the two other possible stereoisomers, of m.p. 126° C. and 106° C., and $[\alpha]_D^{14}=+88{\cdot}5°$ and $[\alpha]_D^{18}=+48°$ respectively, which up to the present have not been found in nature; the two latter are both converted to dihydrocinchotoxine by boiling with dilute acetic acid. Cinchotoxine, $C_9H_6N.CO.(CH_2)_2.C_7H_{12}N$, 6-methoxyquinolyl-4-methylketone, and 6-methoxyquinolyl-4-piperidylmethylketone, yield on reduction respectively cinchotoxol, a yellow oil, 6-methoxyquinolyl-4-methylcarbinol, m.p. 120°—121° C., and 6-methoxyquinolyl-4-piperidinomethylcarbinol,, m.p. 109° C. (B) The use is claimed of esters having the general formula $R'.CH_2COO.R''$, in which R' is an N-acylated basic residue instead of an alkyl group, as claimed in the chief patent. N-Benzoylhomocincholoipon ethyl ester condenses with quinoline-4-carboxylic acid ethyl ester at 80° C. in the presence of sodium ethoxide forming a β-ketone acid ester, which on boiling with hydrochloric acid yield a quinolyl ketone identical with dihydrocinchotoxine, the transformation product of dihydrocinchonine. —L. A. C.

Morphine alkaloids and derivatives of barbituric acid; Preparation of compounds of ——. Ges. für Chem. Ind. in Basel. G.P. 330,814, 6.6.17. Addn. to 322,335 (E.P. 107,409; J., 1917, 979).

ANÆSTHETICS for use in inducing " twilight sleep " are prepared by the action of arylalkylbarbituric acids on morphine alkaloids, as described in the chief patent. Morphinephenylethylbarbituric acid, ethylmorphinephenylethylbarbituric acid, and codeinephenylethylbarbituric acid melt respectively at 250°, 87°, and 80° C.—L. A. C.

Iron-albumin compounds; Preparation of water-soluble ——. Bauer und Co. G.P. 330,815, 11.4.19.

AN aqueous solution of albumose is added to a solution containing ferric nucleate and a neutral salt of an organic acid, such as sodium nucleate, trisodium citrate, or potassium sodium tartrate, until a test portion gives with yellow ammonium sulphide no black precipitate of iron sulphide, even after several hours, but yields a clear bluish-green solution; the solution is then evaporated to dryness. Ferric nucleate is prepared as a flesh-coloured precipitate by the addition of ferric chloride to sodium nucleate in aqueous solution.—L. A. C.

Mercury sludge [obtained, e.g., in the manufacture of acetaldehyde from acetylene]; Recovery of mercury from ——. Consortium für Elektrochem. Ind. G.m.b.H. G.P. 332,202, 30.8.17.

THE water is removed by heating the sludge below 155° C.—L. A. C.

Ferments, enzymes, alkaloids and other substances; Extraction of —— from animal organs and plants. Gebr. Schubert. G.P. 334,660, 23.12.17.

THE fresh or dried material is mixed with sufficient water to form later with calcium chloride a solution which remains liquid well below 0° C. The moistened material is frozen and thoroughly comminuted, and calcium chloride is then added, whereupon liquefaction occurs. The calcium chloride solution formed, containing the substance required, is separated from the residual mass and worked up. The calcium chloride may be precipitated from this solution by an excess of salt, and after centrifuging, the liquid is concentrated to the required extent. The process ensures a very thorough disintegration of the tissues and a complete extraction of the substance required, *e.g.*, pepsin from sheep's stomach, active principles from various glands, etc. —J. H. L.

Petroleum; Production of a preparation [embrocation] from crude ——. Chem. Werke Grenzach A.-G. G.P. 334,916, 4.2.19.

CRUDE petroleum, freed from its more volatile constituents, is treated with hypochlorous acid or salts thereof, and afterwards with feebly basic oxides, hydroxides, or basic salts. The hypochlorous acid combines with unsaturated constituents of the petroleum and prevents any irritating effect when the latter is employed as an embrocation in cases of horse scabies and similar affections. The added bases neutralise acid constituents and give the product the consistency of an emulsified salve readily liquefied on warming.—J. H. L.

Alcohol and ether vapours. U.S.P. 1,376,069. *See* I.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Photomechanical designs, pictures, or printing surfaces; Process of producing ——. F. Hausleiter. E.P. 139,472, 23.2.20. Conv., 19.8.14.

A NEGATIVE on a transparent support is developed with a developer which hardens the gelatin in the neighbourhood of the image. The unexposed parts are washed away, and the remaining image is stained with a suitable dye to increase its opacity to the light to which bitumen is sensitive, and is then coated with bitumen, exposed from the back and developed in the usual way.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

PATENTS.

Explosive. B. F. Halvorsen. U.S.P. 1,375,588, 19.4.21. Appl., 4.12.19.

A NITRO-DERIVATVE of urea is utilised as an explosive.—W. J. W.

Explosive composition. Explosive. F. Olsen. U.S.P. (A) 1,376,029 and (B) 1,376,030, 26.4.21. Appl., 22.5.20 and 15.1.21.

(A) AN explosive composition contains an inorganic

perchlorate, a nitro-hydrocarbon, a propellent powder, a non-explosive combustible substance, a chlorine-fixing material, and a material for regulating the flame-temperature. (B) A nitro-starch explosive is mixed with a propellent powder.
—W. J. W.

Potassium perchlorate explosives. Chem. Fabr. von Heyden A.-G. G.P. (A) 298,568, (B) 300,669, and (C) 303,330, 6.12.16.

(A) A MIXTURE of potassium perchlorate, liquid hydrocarbons, and finely-divided iron, without a nitro-compound, gives an explosive which can be readily detonated. (B) By the addition of ammonium perchlorate to potassium perchlorate explosives, not containing a nitro-compound, the proportion of hydrocarbons may be increased. (C) The use of nitroglycerin in potassium perchlorate explosives may be dispensed with and cheapness thereby increased, by adding an appreciable amount of chlorate, exceeding the 0·2% present in commercial pure potassium perchlorate. The resulting explosive has a high degree of safety.—W. J. W.

Guncotton; Process for stabilising ——. Riensberg. G.P. 299,039, 17.8.16.

THE water used for the purification of guncotton is heated in boilers which are separated from the stabilising vats, and is automatically supplied to, and drawn from, the vats.—W. J. W.

Smokeless powders; Manufacture of ——. Claessen. G.P. 299,760, 15.10.14.

GELATINISATION of smokeless powders, containing nitrocellulose and less than 30% of nitroglycerin or a nitro-compound, is effected, without the aid of a volatile solvent, by incorporating them at a temperature below 100° C., and raising the temperature of 100° C. after organic materials such as resin, diphenylamine, paraffin, etc., have been added. To prevent these substances permeating the powder and retarding its rate of combustion, a protecting film may be produced on the surface of the powder by adding substances such as starch, tragacanth, or gum arabic, which are insoluble in the nitroglycerin or nitro-compound, before introducing the other organic materials.—W. J. W.

Liquid air explosives; Manufacture of ——. Westfälische Berggewerkschaftskasse. G.P. 300,728, 7.1.16.

IN the preparation of liquid air explosives, cork meal constitutes a suitable ingredient, inasmuch as it can absorb 6·7—7 times its weight of liquid oxygen and does not consume much oxygen on detonation. Liquid air explosives containing cork meal retain their sensitiveness to detonation for a longer period than those in which the absorbent consists of wood meal.—W. J. W.

Liquid air explosives; Manufacture of ——. B. Diamand. G.P. 304,300, 1.6.17.

LIQUID hydrocarbons or their compounds are absorbed by, or crystallised in, moss or peat, which is then impregnated with liquid air or oxygen. Both moss and peat retain their elasticity even after absorption of the hydrocarbons, and are therefore readily formed into cartridges.—W. J. W.

Detonating compositions containing lead azide and nitro-compounds. W. Eschbach. G.P. 305,100, 1.1.18.

INFUSORIAL earth, or powdered asbestos, is added to lead azide compositions. Explosives obtained by this means are especially suitable for detonating cartridges which have been steeped in liquid oxygen.—W. J. W

Gunpowder and smokeless powder; Manufacture of an explosive consisting of a mixture of ——. Claessen. G.P. 308,538, 5.1.18.

A MIXTURE of gunpowder and smokeless powder consisting of nitroglycerin and nitrocellulose is less hygroscopic and leaves a smaller residue on combustion than ordinary gunpowder; such an addition to gunpowder therefore ensures more regular combustion.—W. J. W.

Chlorate explosives; Manufacture of granulated ——. Fürstlich Plessische Miedziankitfabrik. G.P. 307,100, 29.11.17.

SULPHITE-CELLULOSE waste liquors are added to the other ingredients of chlorate explosives, the moist mass being subsequently forced through sieves and dried. The granular explosive thus produced has a high efficiency.—W. J. W.

Signals; Mixtures for light and smoke ——. A. Lang. G.P. 307,640, 8.5.17. Addn. to 265,656 (J., 1913, 1169).

THE mixtures described in the original patent as suitable for exterminating plant pests may be adapted for use in signals by the addition of light- and smoke-producing substances, *e.g.*, metallic powders, such as lead or zinc, or compounds of cadmium and arsenic. Such mixtures will burn even in water.—W. J. W.

Explosive propellants. O. Silberrad. E.P. 150,002, 11.8.20. Conv., 21.8.19.

SEE U.S.P. 1,349,983 of 1920; J., 1920, 676 A.

XXIII.—ANALYSIS.

Zinc; Volumetric estimation of ——. I. M. Kolthoff and J. C. van Dijk. Pharm. Weekblad, 1921, **58**, 538—553.

THE mercury double thiocyanate method is found to be best. The reagent is prepared by dissolving 1 mol. of mercuric nitrate in 4 mols. of potassium thiocyanate, and is added in excess to the zinc solution. The whole is made up to a known volume and filtered, and the excess of reagent titrated in an aliquot part of the filtrate by means of mercuric nitrate, using iron alum as indicator. (*Cf.* J.C.S., June.)—S. I. L.

Cobalt; Nitroso-R-salt, a new reagent for the detection of ——. H. S. van Klooster. J. Amer. Chem. Soc., 1921, **43**, 746—749.

NITROSO-R-SALT gives an intense red coloration or precipitate with cobalt salts, by means of which 1 pt. of cobalt may be detected in presence of 200 pts. of nickel. The salt is prepared by the action of nitrous acid on sodium 2-naphthol-3.6-disulphonate. The test is carried out as follows: To 2 c.c. of a dilute solution of the salt to be tested (1·5—2·0 g. in 100 c.c. of water) is added 1 g. of sodium acetate and 2 c.c. of nitroso-R-salt solution (0·5 g. in 100 c.c. of water). The liquid is boiled over a small flame and after the gradual addition of 1 c.c. of nitric acid (sp. gr. 1·4) the boiling is continued for at least 1 min. A permanent change in colour towards red indicates the presence of cobalt. The colours produced by other metals are destroyed by the nitric acid. It is essential that the original solution should not be acid, for this retards and may prevent the formation of the red coloration. (*Cf.* J.C.S., June.)—J. F. S.

Arsenic reduction tube; Electrically heated ——. K. Zwicknagl. Chem.-Zeit., 1921, **45**, 418.

The tube of a Marsh apparatus is heated by means of a length of resistance wire wound round it and insulated with asbestos-paper. To ensure better contact of the gases with the heated wall of the tube the latter is flattened so that its cross section is about 2×14 mm.—W. P. S.

Hydrogen ion concentration; Colorimetric determination of —— in small quantities of fluid. L. D. Felton. J. Biol. Chem., 1921, 46, 299—305.

Drops of indicator solutions are mixed on a porcelain plate with drops of the solution to be examined and with drops of known buffer mixtures respectively. (*Cf.* J.C.S., June.)—G. B.

Protein analysis; Modification of the Van Slyke method of ——. P. Menaul. J. Biol. Chem., 1921, 46, 351—352. (*Cf.* J., 1911, 1135.)

The humin is precipitated with phosphotungstic acid instead of with calcium oxide. (*Cf.* J.C.S., June.)—G. B.

Chlorine, sulphur, and phosphorus in organic substances; Determination of ——. A. Grégoire and E. Carpiaux. Bull. Soc. Chim. Belg., 1919, 28, 331—335.

The method, which is designed for use with plant products, consists in digesting the material with concentrated nitric acid and a little potassium permanganate in a distillation flask, the exit tube from which passes through a short condenser. At its lower end the exit tube is connected with the absorption device, which consists of two inclined tubes, 18—22 mm. diam., and about 1 m. long, arranged crosswise and joined by a connecting tube. To improve the contact between the absorbent and the vapours, pieces of glass tubing are placed in the inclined tubes, each piece being drawn out at one end which projects into the end of the next higher piece of tubing. The sulphur and phosphorus remain in the distillation flask as sulphuric and phosphoric acids, whilst the chlorine distils off along with nitrous fumes, and is collected in water as hydrochloric acid. The three acids are then estimated in the usual way.—W. G.

Patents.

Gas analysis; Apparatus and process for ——. E. K. Rideal and H. S. Taylor. U.S.P. 1,375,933, 26.4.21. Appl., 5.3.19.

See E.P. 134,243 of 1918; J., 1920, 23 A.

Gas calorimeters [; Regulating flow of water to ——]. J. H. Fairweather. E.P. 162,826, 11.2.20.

Ultra-filters. G.P. 334,063. *See* I.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Brettell (Soc. Anon. les Ateliers Réunis). Pulverisers and crushing-mills. 14,499. May 25.

Broadbent, Claughton, Hamilton, Jack, and Smith. Clarification of waste lubricants etc. 14,607. May 26.

Burden. Reducing or disintegrating machines. 14,848. May 28.

Gregory. Extinguishing-fluids. 15,127. May 31.

Minerals Separation, Ltd., and Williams. 14,812. *See* X.

Möller. Apparatus for separating suspended bodies from gaseous fluids etc. 15,118. May 31. (Ger., 31.7.14.)

Pohlmann. Method of operating refrigerating-plants. 15,200. June 1. (Ger., 4.6.20.)

Rhodes. Barrel filter. 14,486. May 25.

Rigby. Heating or cooling liquids or admixed solids and liquids in evaporative etc. treatment. 14,599. May 26.

Sturgeon. Centrifugal separators. 15,038. May 31.

Williams. Tunnel ovens. 15,120. May 31.

Complete Specifications Accepted.

2242 (1920). Conder and Vivian. Crushers with vibrating jaws. (163,750.) June 8.

2243 (1920). Conder and Vivian. Roller mills. (163,751.) June 8.

3895 (1920). Josse and Gensecke. Evaporation of liquors. (138,871.) June 1.

5558 (1920). Testrup, and Techno-Chemical Laboratories, Ltd. Evaporating or distilling apparatus. (163,793.) June 8.

5860 (1920). Fuller-Lehigh Co. Pulverising-mills. (139,511.) June 1.

7189 (1920). Soc. l'Air Liquide. Apparatus for carrying out exothermic chemical reactions under high temperatures and pressures. (140,089.) June 8.

8228 (1920). Ely. Rotary furnaces. (163,543.) June 1.

8247 (1920). Read. Pulverising-machines. (163,856.) June 8.

10,387 (1920). Vanneau. Grinding or crushing apparatus. (141,721.) June 1.

11,927 (1920). Grondal. Apparatus for lixiviating granular or pulverulent material. (142,493.) June 8.

18,646 (1920). Stumpf. Heating and purifying boiler feed-water. (146,522.) June 8.

23,317 (1920). Alexander (Best). *See* II.

31,616 (1920). Velten. Apparatus for separating materials of different specific gravity. (155,570.) June 1.

35,921 (1920). Soc. d'Utilisation des Combustibles Pulverisés. Rotary drying-apparatus. (163,653.) June 1.

6986 and 6988 (1921). Kennedy. Gyratory crushing-apparatus. (160,463 and 160,465.) June 1.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Beasley, Stenning, and Minerals Separation, Ltd. Production of coal briquettes. 15,066. May 31.

Benjamin and Treneer. Purification of hydrocarbons. 15,080. May 31. (U.S., 4.6.20.)

Clabaut and Coureyeur. Gas-generators. 15,248. June 1. (Fr., 11.6.20.)

Cunningham and Stern. Production of water-gas. 15,001. May 30.

Helps. Manufacture and distribution of gas. 14,605 and 14,725. May 26 and 27.

Illingworth. Coking coal. 14,676. May 26.

Klee. 15,458. *See* XXIII.

Maclaurin. Water-gas plant. 15,203. June 1.

Marshall. Retorts for treating carbonaceous etc. materials. 14,472. May 24.

O'Byrne. Recovery and preparation of peat, turf, etc. for fuel etc. 14,428. May 24.

Piron. Regenerative coke-ovens. 15,363. June 2.

Poore. Destructive distillation of wood etc. 14,820. May 27.

Rigby. Heat-regenerating systems of gas-producer plants etc. 14,598. May 26.

Shields (Mine Safety Appliance Co.). Gas-purifying compositions, and their production. 15,330. June 2.

Tully. Manufacture of gas for heating and lighting. 15,254. June 1.

Umpleby. Gas producers and/or retorts. 14,276. May 23.

Complete Specifications Accepted.

6426 (1919). McLeod. Apparatus for carbonising and distilling moist carbonaceous materials. (163,343.) June 1.

18,151 (1919). Dalley (Greenway). Distillation or cracking of hydrocarbon oils. (163,347.) June 1.

28,614 (1919). Illing and Kelly. Treatment of petroleum etc. (163,363.) June 1.

6235 (1920). Williams, Francis, and Bynea Steel Works, Ltd. Gas-producers. (163,513.) June 1.

6509 (1920). Fyleman. Separation of mineral oils etc. from sand or rock. (163,519.) June 1.

8955 (1920). International Coal Products Corp. Manufacture of carbonised fuel briquettes. (140,821.) June 8.

17,613 (1920). Nasspress Ges. Utilising coal slimes. (146,264.) June 8.

19,151 (1920). Meyer. Carbonising solid fuels in a circulating current of gas. (147,117.) June 8.

19,308 (1920). Otto u. Co. Coke-ovens. (147,229.) June 1.

19,310 (1920). Otto u. Co. Coke-ovens. (147,231.) June 8.

19,512 (1920). Collin A.-G. Recovery of by-products from fuel gases. (147,633.) June 1.

20,608 (1920). Riedel. Recovery of nitrogen contained in fuel. (148,784.) June 8.

23,317 (1920). Alexander (Best, Inc.). Oxidation of finely subdivided material, and combustion apparatus therefor. (162,623.) June 1.

2833 (1921). Illing and Kelly. Production of asphalt from petroleum etc. (163,656.) June 1.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bowler. Decorticating-machine and chemical apparatus for treating palm fibres. 14,374. May 24.

Brodie. Treatment of esparto grass, fibrous material, etc., for manufacture of paper. 15,205. June 1.

Budde, and Hendon Paper Works Co. Manufacture of hydro-oxycellulose, a new xanthogenated compound therefrom, etc. 14,852. May 28.

Dreaper. Spinning filaments of artificial silk. 14,256. May 23.

Dreyfus. Coating or treating surfaces etc. 14,802. May 27.

Dreyfus. 14,861. *See* IX.

Complete Specifications Accepted.

999 (1920). Braun. Manufacture of cellulose. (137,831.) June 1.

3916 (1920). Fearnley. Manufacture of paper. (163,421.) June 1.

4693 (1920). Braun. Manufacture of cellulose. (139,171.) June 1.

4877 (1920). Bronnert. Manufacture of viscose silk. (163,466.) June 1.

5983 (1920). Bronnert. Manufacture of viscose silk. (163,817.) June 8.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Calico Printers' Assoc., Ltd. Printing variegated effects on fabrics etc. 15,414. June 3.

Charlesworth. Dyeing processes. 15,482. June 4.

Silbereisen. Apparatus for continuous scouring, dyeing, etc. of fabrics in the piece. 14,441. May 24. (Fr., 2.3.21.)

Complete Specifications Accepted.

5188 (1920). King and Haines. Bleaching and bleaching compounds. (146,078.) June 1.

14,820 (1920). Poulson. Sizing textile fabrics etc. (163,915.) June 8.

1343 (1921). Krantz. Dyeing yarn on bobbins in circulating dye liquor. (157,418.) June 8.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Casale and Leprestre. Apparatus for catalytic synthesis of ammonia. 14,459. May 24.

Elektrizitätswerk Lonza. Treatment of residuary ammonium chloride lyes. 14,900. May 28. (Switz., 29.5.20.)

Evershed and Gitsham. Manufacture of sulphate of lead. 15,078. May 31.

Griffith. Schlippe's salt etc. 14,920. May 30.

Heenan and Froude, Ltd., and Walker. Concentration of brine. 14,501. May 25.

Jourdan. Ammonia-soda process. 15,426. June 3. (Ital., 3.6.20.)

Wright and Wright. Production of ammonium salts and coloured pigments. 15,023. May 31.

Complete Specifications Accepted.

9994 (1920). Phillips. Manufacture of readily soluble alkali silicates. (163,877.) June 8.

15,458 (1920). Badische Anilin u. Soda Fabrik. *See* XVI.

20,566 (1920). Jaubert. Apparatus for purifying hydrogen or oxygen. (148,564.) June 1.

VIII.—GLASS; CERAMICS.

Applications.

Atkinson, and Stein and Atkinson. Drying china clay, etc. 15,304. June 2.

Deussing. Production of artificial meerschaum. 14,592. May 25. (Ger., 7.6.20.)

Techno-Chemical Laboratories, Ltd., and Testrup. Manufacture of china clay. 14,992. May 30.

Complete Specifications Accepted.

5597 (1919). Gowen. Manufacture of refractory materials. (124,208.) June 1.

25,262 (1920). Festa. *See* X.

IX.—BUILDING MATERIALS.

Applications.

Dreyfus. Treatment of wood, paper, etc. 14,861. May 28.

Hawes. Substitute for wood etc. 14,782. May 27.

Complete Specifications Accepted.

26,280 (1919). Dale. Concrete etc. (163,731.) June 8.

4337 (1920). Mattison. Manufacture of fibrous cement products. (138,921.) June 1.

4398 (1920). Lewis. Continuous kilns for burning bricks etc. (163,439.) June 1.

4890 (1920). Brothers. Manufacture of plaster of Paris. (163,468.) June 1.

10,302 (1920). Milner and Robinson. Manufacture of bricks, blocks, etc. from blast-furnace slag. (163,569.) June 1.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Alloy Welding Processes, Ltd., and Jones. Electrodes, welding rods, and soldering sticks. 15,435. June 3.

Aymard. Treatment of silica-bearing ores. 14,946. May 30.

Jones, and Sylvette, Ltd. Nickel alloys. 14,603. May 26.

Loke. Direct reduction of titanic-iron ores or slags. 14,813. May 27.

Marshall. Anticorrosive and antifouling composition for metals. 15,174. June 1.

Minerals Separation, Ltd., and Williams. Prevention of dusting of powdered minerals. 14,812. May 27.

Thompson (Aikens). Electrolytic refining of tin. 15,047. May 31.

Turner. Production of carbon-free ferromolybdenum. 15,179. June 1.

Wardall. Aluminium alloys. 14,544. May 25.

Complete Specifications Accepted.

19,015 (1919). Niiranen and Hibbert. Recovery or separation of metals. (163,348.) June 1.

7139 (1920) Irons. Manufacture of steel. (163,526.) June 1.

8468 (1920). Grondal. Apparatus for use in concentrating ores etc. (140,775.) June 1.

9136 (1920). Rustproofing Syndicate, Ltd., and Newman. Metal pickling or cleaning. (163,868.) June 8.

9250 (1920). Vermaes, and Syndicaat Electro-Staal. Manufacture of iron from iron ores. (163,561.) June 1.

10,302 (1920). Milner and Robinson. *See* IX.

17,393 (1920). Krupp A.-G. Production of low-carbon and low-silicon ferrochromium. (145,711.) June 8.

20,131 (1920). Zelewski. Zinc-extracting furnaces with vertical retorts. (148,210.) June 1.

20,181 and 20,200 (1920). Dagory. Removal of copper deposit from the bores of guns. (148,250 and 148,263.) June 8.

22,562 (1920). Lavandeyra. Aluminium alloys. (149,638.) June 8.

25,262 (1920). Festa. Furnaces for fusing steel and other metals, baking ceramic products, refractory materials, etc. (155,231.) June 1.

5614 (1921). Brown, Boveri & Co. *See* XI.

6417 (1921). Passalacqua. Soldering aluminium or aluminium alloys. (159,480.) June 1.

XI.—ELECTRO-CHEMISTRY.

Applications.

Alloy Welding Processes, Ltd., and Jones. 15,435. *See* X.

Boite, Edridge, and Lyto, Ltd. Galvanic batteries or cells. 14,302. May 23.

Chloride Electrical Storage Co., Ltd., and Heap. Secondary electric batteries. 14,571. May 25.

Loke. Electric etc. furnaces. 14,814. May 27.

Philippart. Electric accumulators. 14,543. May 25. (Fr., 31.5.20.)

Rennerfelt. Electric furnaces. 14,702. May 26. (Sweden, 2.6.20.)

Thompson (Aikens). 15,047. *See* X.

Complete Specification Accepted.

5614 (1921). A.-G. Brown, Boveri & Co. Electrically heated muffle furnaces. (159,195.) June 1.

XII.—FATS; OILS; WAXES.

Applications.

Bolton and Lush. Recovery of oil from and purification of fuller's earth, charcoal, etc. for re-use in oil refining. 14,413. May 24.

Krebitz. Separating saponaceous matter from lime sludge. 15,428. June 3.

Complete Specification Accepted.

23,957 (1919). Bolton and Lush. Conversion of fatty acids or oils, or fats containing free fatty acids, into glycerides. (163,352.) June 1.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Clarke, and Cookson and Co. Manufacture of paints and enamels. 14,956. May 30.

Macpherson. Preparation of pigments from titaniferous laterites. 15,308. June 2.

Pearson. Treatment of acaroid resins. 14,753. May 27.

Wright and Wright. 15,023. *See* VII.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Abrey. Plastic material made from casein. 14,948. May 30.

Carmichael and Ockleston. Tanning. 14,943. May 30.

Glover and Martin. Preparation of chrome tanning agent. 14,654. May 26.

Complete Specifications Accepted.

20,665 (1919). Serle. Production of casein cements. (163,349.) June 1.

5690 (1920). Melamid. Manufacture of artificial tanning substances. (147,534.) June 8.

13,006 (1920). Bayerische Maschinenfabr. Regensburg. Rotary tanning and fulling drums. (143,228.) June 1.

19,964 (1920). Korn. Production of a substitute for leather etc. (147,910.) June 8.

XVI.—SOILS; FERTILISERS.

Complete Specifications Accepted.

28,304 (1919). Wolf and Fry. Manures. (163,359.) June 1.

3687 (1920). Sams. Manure and method of making same. (163,417.) June 1.

15,458 (1920). Badische Anilin u. Soda Fabrik. Transforming ammonia into a salt for use as a fertiliser. (144,659.) June 8.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Classen. Manufacture of sugar from wood etc. 15,249. June 1. (Ger., 4.6.20.)

Petree. Manufacture of sugar. 15,457. June 3.

Complete Specifications Accepted.

16,322 (1920). Patterson. Manufacture of syrups and sugar. (163,924.) June 8.

22,021 (1920). Tavroges, Roche, and Martin. Purification of crude lactose. (163,937.) June 8.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specification Accepted.

28,594 (1919). Meyer. Production of yeast. (144,244.) June 8.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Atkinson, and Stein and Atkinson. Destruction of refuse. 15,305. June 2.

Howles. Insecticides, fruit washes, etc. 15,413. June 3.

Nielsen. Sterilising milk. 15,136. May 31.

Torrance. Manufacture of chocolate or cocoa products. 15,514. June 4.

Complete Specifications Accepted.

5707 (1920). Haddan (Naaml. Vennoots. Algem. Norit Maatsch.). Treating large quantities of liquids with purifying reagents in a continuous manner. (163,505.) June 1.

8310 (1920). Horlick. Food compound. (140,472.) June 8.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of methylsulphites of secondary aromatic-aliphatic amines. 14,986. May 30. (Ger., 31.5.20.)

Goodyear Tire and Rubber Co. Process of making thioureas. 15,088. May 31. (U.S., 5.6.20.)

Peufaillit. Industrial preparation of derivatives of bornyle for preparing synthetic camphor. 15,441. June 3. (Belg., 10.1.21.)

Complete Specifications Accepted.

9667 (1920). Imray (Soc. Chem. Industry in Basle). Manufacture of mercury compounds of glucosides. (163,874.) June 8.

15,621 (1920). Du Pont de Nemours and Co. Production of tetra-substituted ureas. (144,681.) June 8.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Davies. Manufacture of photographic papers. 14,549. May 25.

Griffith. 14,920. *See* VII.

XXII.—EXPLOSIVES; MATCHES.

Complete Specification Accepted.

25,486 (1920). Lundsgaard. Explosives. (163,946.) June 8.

XXIII.—ANALYSIS.

Applications.

Hedley. Gas combustion furnaces for organic analysis. 14,262. May 23.

Klee. Apparatus for determining flash points of oils etc. 15,458. June 3.

Complete Specification Accepted.

14,621 (1920). Svenska Aktiebolaget Mono. Apparatus for use in analysing gas mixtures. (143,918.) June 8.

JOURNAL OF THE SOCIETY OF

CHEMICAL INDUSTRY

Vol. XL. No. 1 January 15, 1921

REVIEW

SOCIETY OF CHEMICAL INDUSTRY.

CO-OPERATION IN PUBLICATION.

The memorandum submitted by the Federal Council for Pure and Applied Chemistry for co-operation in the publication of chemical literature, which we have been allowed to bring before our members through the courtesy of our President, Sir William Pope, who is also the Chairman of the Federal Council, is one of great moment to this Society.

The outstanding national importance of securing a full record of chemical literature so that we are no longer dependent upon the publications of other countries is recognised on all sides, and the need for co-operation is equally evident if this desirable objective is to be achieved. Such co-operation has been in the minds of many for a considerable period, but the initial difficulties in the way of its successful realisation, with due regard to the individuality of each of the Societies concerned, have hitherto proved a serious barrier. The conditions that have resulted from the war and the present economic pressure have accentuated the need from every point of view, and it is accordingly to be hoped that the present proposal will be considered from a wide and comprehensive standpoint and with a broad outlook towards the future of pure and applied chemistry in this country.

The memorandum, which was drawn up by the Federal Council at its meeting held on November 3, was accompanied by a covering letter suggesting that the Councils of the Chemical Society and of this Society should each appoint four representatives to meet as a Joint Committee to discuss the questions raised; this suggestion has been acted upon, and the representatives have been instructed to report the results of their deliberations to their respective Councils as well as to the Federal Council.

From the standpoint of this Society this proposal brings with it a welcome opportunity for a full consideration of the Society's publications. Our Journal is our great asset, and the Council and the Publications Committee fully realise their responsibility to make it as efficient as possible, and to maintain its high standard and reputation. The Transactions, the Abstracts and the Review represent a record of chemical literature which has proved of the utmost value and which must be maintained in any co-operative scheme of publication. For progressive development, responsible, informed and constructive proposals will always be welcomed, and we look especially to the younger members for help in this direction. Both in the interests of this Society and in the wider interests of the chemical industries of the nation, the improvement of our chemical literature and its more efficient organisation merit serious attention and wise counsel if we are to march successfully in the competitive advance of science and its technical applications.

ON CHEMICAL PERIODICAL LITERATURE.

(Memorandum from the Federal Council for Pure and Applied Chemistry.)

In past years the desirability of closer co-operation for publication between the several societies which issue chemical journals has often been discussed, but, although certain minor mutual arrangements have been made, no effective joint action has been taken. The main object has been to retain a high standard of publication and, in the absence of financial embarrassment, the extra cost of the luxury of independent publication has proved of quite secondary importance.

The recently established economic conditions have, however, introduced financial difficulties; our large chemical societies have had to raise their subscriptions and to abbreviate their publications. The two chief societies receive considerable financial assistance from their advertisements, which have notably increased during recent years; in fact, the Society of Chemical Industry draws a much larger income from advertisements than from the annual subscriptions of its members. With the disappearance of the Excess Profits Duty it is to be anticipated that advertisement matter will be more difficult to obtain; it is thus likely that further increases in the annual subscriptions will be necessary in the near future.

The whole subject of chemical periodical literature should therefore now be considered afresh in view of the incidence of economic pressure as a new factor. It seems necessary to consider whether our present method of dealing with the corporate interests of chemistry, as represented by periodicals, cannot be so modified as to ensure greater economy—that is, greater efficiency.

For the present it is perhaps convenient to restrict inquiry to the Chemical Society and the Society of Chemical Industry; at this preliminary stage the consideration of the circumstances of the many other societies having chemical interests will needlessly complicate the issues. The third large chemical society, the Institute of Chemistry, being a qualifying body, is so different in type from the other two that it also may be left out of immediate consideration. We may therefore consider in what way the incomes of the two large societies named above can be so expended as to yield a greater return to their members than is at present attained. As a preliminary it will be useful to note the practice in other countries.

In the United States, the American Chemical Society publishes original scientific papers in its monthly journal, which absorbed the *American Chemical Journal* some years ago, and also publishes monthly the *Journal of Industrial and Engineering Chemistry*, which contains ephemeral matter and market reports in addition to original papers on technical chemistry. This Society also issues *Chemical Abstracts*, a fortnightly publication which aims at abstracting every published article of chemical interest; it is now constructing a formula index to include inorganic as well as

organic substances with a view to incorporating this in its decennial index.

In Germany, efforts were being made before the war to gather control of all the chemical periodical publications into one set of hands. In 1897, the German Chemical Society, which previously published abstracts as a part of the *Berichte*, acquired the *Chemisches Zentralblatt* and has since used this for the publication of chemical abstracts; in 1919, the *Chemisches Zentralblatt* was divided into two parts, scientific and technical, which now appear separately.* Later this Society secured to its members preferential rates of subscription to the *Zeitschrift für angewandte Chemie* and to *Liebig's Annalen* and, with its possession of the large compendia, such as "Beilstein" and "Richter," was evidently intending to concentrate all important periodic publications, academic and technical, under its own guidance.

In Holland, the *Nederlandsche Chemische Vereenigung*, numbering about 1000 members, issues a monthly journal of original scientific papers, the *Recueil des Travaux Chimiques des Pays-Bas*, and a weekly journal of technical and general interest, the *Chemisch Weekblad*, which also gives market prices. The Society also publishes the *Chemisch Jaarboekje* in three parts. The first part gives particulars of the Association and a list of its members and officers, together with a classified and indexed list of Dutch firms concerned with chemical products or necessaries, and states the specialities of these firms; the second consists of tables of constants similar to but smaller than Biedermann's *Kalender*. The third part forms a very extensive chemical bibliography stating in which of the Dutch libraries each journal or book is to be found.

In Italy, the Associazione Italiana di Chimica Generale ed Applicata publishes monthly the *Gazzetta Chimica Italiana*, a purely scientific journal, and also monthly the *Giornale di Chimica Industriale ed Applicata*, which contains technical, general, and commercial matter.

In France, the Société Chimique de France was until two years ago the only large chemical organisation; recently, however, the Société de Chimie Industrielle has been formed and has become very influential. As yet these two societies are entirely unconnected; each publishes its own original papers and abstracts. The relations between the two French societies seem practically identical with those which subsist between the Chemical Society and the Society of Chemical Industry.

In this country the Chemical Society issues the following publications:—

1. Transactions of the Chemical Society.
2. Abstracts of the Chemical Society.
3. List of members of the Chemical Society.
4. Annual reports on the progress of chemistry.

The Society of Chemical Industry issues the following:—

5. The Transactions, consisting of original papers.
6. The Review, containing matter largely of transient interest, with reviews of books.
7. The Abstracts of original papers and patents.
8. List of members of the Society.
9. Annual reports on the progress of technical chemistry.

Numbers 5, 6 and 7 are published together in fortnightly parts but with separate pagination.

The last inquiry showed that of the 3000 Fellows of the Chemical Society, and the 4000 members of the Society of Chemical Industry only 1000 are common to both; it appeared that an overlap of abstracts to the extent of about 15 or 20 per cent. occurred as between the two journals of abstracts, but it is probable that this is now reduced to little more than 5 per cent.

It is impossible to consider the above series of publications issued and the editorial establishments maintained by these two entirely independer societies without concluding that economies a possible. Further, the fact that information ephemeral or popular interest only appears fortnightly in the *Journal of the Society of Chemica Industry*, has led to the appearance of weekl journals under private control which conve such information more promptly and, in additio gain support from the more frequent distributio of advertisement matter; this factor naturally de preciates the value of the journals of the societie as advertising media.

The consideration of the tendency of foreig practice and of the circumstances of publication b the Chemical Society and the Society of Chemica Industry leads to the conclusion that increase economy and efficiency would be attained if the amalgamated into a "Chemical Federation" fo purposes of publication. As to what set of publica tions they should issue provides matter for detaile discussion, and it is now only tentatively suggeste that they should aim at the production of the fol lowing series:—

1. Transactions of the Chemical Society.
2. Transactions of the Society of Chemical Industry.
3. Chemical Abstracts, scientific and technical, purporting to be a complete collection of abstracts of original papers and patents, together with a list of books, Government reports, and the like.
4. A joint annual report on the progress of pure and applied chemistry.
5. A list of members of the chemical profession with their addresses and an indication of the societies to which they belong.
6. A weekly journal, containing the proceedings and notices of both societies, general summaries, reports of meetings, notices of books, parliamentary and legal information, company reports, market prices, notes of appointments, letters from correspondents, and the like.

Issues 1 and 2 would probably be made monthly and in much their present form. Issue 3 might appear fortnightly and aim at being as complete as the American *Chemical Abstracts*; it would probably be divided into scientific and technical sections like the *Zentralblatt*, and should be completed annually by a formula index, somewhat on the American plan, which could be employed in the production of complete indexes to the literature. Publication 5 could be made an indispensable chemical directory, giving particulars about learned and technical societies, possibly also lists of chemical firms and the like; it should be possible to secure the co-operation in this production of all the societies connected with chemistry, such as the Institute of Chemistry, the Society of Public Analysts, etc., with a view to their using this as their annual list of members. It could be made more complete by including particulars of chemical companies similar to those given in the Stock Exchange Year Book; its wide circulation would make it a valuable advertising medium, and it might thus pay for itself.

The weekly publication 6 should be more valuable for advertising purposes than our present journals.

In carrying out such a scheme as the above it would be possible to allow each Fellow of the Chemical Society to subscribe for 1, 3, 4, 5, and 6, and each member of the Society of Chemical Industry for 2, 3, 4, 5, and 6; also to obtain the remaining publication of the Chemical Federation at a reduced rate in the manner practised in the German Chemical Society. It would be necessary

* [Since the memorandum was drawn up, certain changes in the modes of issue of the *Zentralblatt* and the *Zeit. f. angew. Chem.* have been notified for 1921 (*cf. J.*, Dec. 31, 487 R).—ED.]

to apportion the financial outgoings and incomings as between the two societies; this involves purely actuarial work which can be safely left to professional hands.

COMMITTEES OF COUNCIL AND REPRESENTATIVES ON OUTSIDE BODIES.

Publications Committee.—Messrs. C. A. Keane (convener), E. F. Armstrong, J. L. Baker, W. J. A. Butterfield, F. H. Carr, W. H. Coleman, S. H. Davies, W. R. Hodgkinson, G. T. Morgan, J. A. Reavell, W. F. Reid, and E. Thompson, with the following co-opted members: E. R. Bolton, C. F. Cross, J. T. Dunn, E. Grant Hooper, J. R. Partington, W. J. Rees, and W. G. Wagner.

Finance Committee.—Messrs. E. V. Evans (convener), E. F. Armstrong, J. L. Baker, C. S. Garland, J. Gray, H. Louis, S. Miall, W. F. Reid, and E. Thompson.

General Purposes Committee.—Messrs. S. Miall (convener), F. H. Carr, W. R. Hodgkinson, H. Louis, G. W. Monier-Williams, G. T. Morgan, L. G. Radcliffe, A. Rée, and E. Walls.

Technical, Research, and Allied Societies Committee.—Messrs. J. Allan (convener), E. F. Armstrong, W. A. Bone, J. W. Cobb, A. Holt, D. S. Jerdan, C. A. Keane, H. Levinstein, H. Louis, F. R. O'Shaughnessy, J. A. Reavell, and J. H. Young.

Government and Parliamentary Committee.—Messrs. W. F. Reid (convener), John Allan, J. L. Baker, W. A. Bone, Sir John Brunner, Bart., C. S. Garland, Sir R. A. Hadfield, Bart., S. Miall, and A. Rée.

Literary and Libraries Committee.—Messrs. W. J. A. Butterfield (convener), A. Holt, A. Lauder, R. L. Mond, G. T. Morgan, H. D. Smith, H. Talbot, and S. R. Trotman.

Emergency Committee.—The conveners of the above six committees; the General Secretary to act as convener.

The following have been nominated by the Council to represent the Society on outside bodies:—

Federal Council for Pure and Applied Chemistry.—Dr. C. A. Keane, Dr. S. Miall, and Mr. F. H. Carr.

National Physical Laboratory (General Board).—Sir Wm. J. Pope and Prof. F. G. Donnan.

Conjoint Board of Scientific Societies.—Dr. A. Holt and Dr. C. A. Keane.

Institute of Chemistry Standards Committee.—Dr. A. Holt, Prof. A. R. Ling, and Mr. W. G. Wagner.

British Empire Sugar Research Association.—Prof. A. R. Ling and Mr. J. W. MacDonald.

British Association Fuel Economy Committee.—Mr. E. V. Evans.

Industrial Alcohol Joint Committee.—Dr. E. F. Armstrong and Mr. D. Lloyd Howard.

British Engineering Standards Association.—Aircraft Sub-committee on Chemicals: Prof. W. A. Bone; Sub-committee on Textiles: Mr. C. F. Cross; Sub-committee on Dopes: Dr. J. N. Goldsmith.

Imperial Mineral Resources Bureau.—Lead, Silver, Zinc, and Cadmium Sub-committee: Mr. H. N. Ridge; Aluminium, Magnesium, and Sodium Sub-committee: Dr. R. Seligman; Minor Metals Sub-committee: Mr. W. G. Wagner; Chemical Industries (including Potassium) Sub-committee: Mr. C. S. Garland; Publications and Libraries Sub-committee: Mr. W. J. A. Butterfield; Abstracts Sub-committee: Prof. H. Louis and Mr. T. F. Burton.

NEWS FROM THE SECTIONS.

SHAWINIGAN FALLS.

The inaugural meeting was held on December 13, and was preceded by a dinner at which about sixty members and their guests were present.

The chairman, Dr. F. W. Skirrow, outlined the steps that had been taken to initiate the new Section, and read a cablegram from the President and Council wishing the Section every success on the occasion of its first meeting. Mr. G. MacIntyre then spoke and conveyed the good wishes of the Montreal Section.

The Hon. Walter Mitchell, Provincial Treasurer, addressed the meeting on the Province of Quebec, outlining its remarkable progress in regard to industry, transportation, and agriculture during recent years. The area of the Province, however, was so great—one-quarter that of the United States and five times that of the United Kingdom—and its natural resources so vast that its development had hardly begun. The Gouin administration had greatly increased expenditure on good roads, education, agriculture, and public works, but in such a judicious manner that the *per capita* debt had actually decreased during the past few years, a phenomenon unique in recent political history.

Development of the water-power resources by private capital had been encouraged and assisted by the Government, which even derived a profit from it, whilst the companies were able to sell power at very low rates. Of the 19 million available horse-power in Canada, Quebec possessed 6·85 million h.-p., and of this 875,000 h.-p. had been developed. The Gouin dam at La Loutre, which cost $2,500,000, and was serving an area of 300 sq. miles and impounding 160 billion cb. ft. of water, or twice as much as the Assouan dam in Egypt, had doubled the available horse-power on the St. Maurice River. In consequence, the large industrial towns of Grand'Mere and Shawinigan Falls had been built, and the village of Three Rivers had become a thriving city. Possible developments in other parts of the province were being studied by the Government. In concluding, the speaker pleaded for economy, co-operation between capital and labour, good sense, and good engineering in the difficult times now upon us, and predicted a period of prosperity greater than had been experienced in the past.

Mr. T. H. Wardleworth welcomed the new Section into the brotherhood of the Society which, he said, was not merely British, but imperial in character; as a vice-president, he was pleased to be able to endorse the cabled greeting from the President and Council in London. Great changes had taken place in the application of science to industry during the speaker's life-time. The period of "trial and error" had given way to insistence upon exact methods based upon well-ascertained facts, so that the chemist could reasonably anticipate results not only from laboratory experiments, but from the industrial development of new processes. Referring to the great care which Faraday bestowed upon his experimental researches, it was observed that although his mechanical and physical equipment was crude, his theories were nevertheless corroborated when modern refinements became available. Electricity had supplied the chemist of to-day with new powers and, in consequence, marked advances would be expected from a centre such as Shawinigan; it behoved every member of the new Section to see that these expectations were realised. Dealing with the relation of capital to chemical industry, the speaker emphasised the importance of the capitalist, and remarked upon the lack of education of wage-earners as revealed by thriftless habits. An appeal was made for a better understanding between capital and labour, as the vital interests

of both depended upon active co-operation. The labour problem was not always a question of hours and wages, and this was especially true in a country like Canada which employed cosmopolitan labour; due allowance must be made for national customs and habits.

After a vote of thanks to the speakers had been moved by Mr. Stadler, seconded by Mr. Witherspoon, and replied to by Mr. Wardleworth, the meeting adjourned.

LONDON.

At the meeting held on January 3 at Burlington House, Mr. Julian L. Baker presiding, a paper by Mr. G. H. Thurston on "The Smith Continuous System of Carbonisation" was read, in the author's absence, by Colonel Brentnall. The carbonising process is carried out in two stages. In the first, coal of almost any description, after being dried with hot waste gases and crushed, is heated at 480° C. for 2 hours in cylindrical retorts lined with carborundum, the tar oils and gases being collected. The capacity of each retort is one ton of coal per hour, and mechanical stirrers are used to mix the charge and to move it forward from the inlet to the point of discharge. A coal with 35 per cent. volatile matter gives 5600—6700 cb. ft. of gas with calorific value 650—700 B.Th.U. The solid residue ("semicarbocoal") is briquetted with pitch and then heated for 6 hours at 1090° C. in inclined retorts; heavy oil, pitch, and ammonia are recovered from the volatile products, together with gas of 350—400 B.Th.U. "Carbocoal"—the residual solid—is stated to be an excellent smokeless domestic fuel, and also to be well suited for metallurgical, *e.g.*, blast-furnace, purposes, its crushing strain being 940 lb. per sq. in. The yields obtained from one ton of coal are:—14 cwt. of "carbo-coal," 10,080 cb. ft. of gas, 28 impl. galls. of tar, and 22·24 lb. of ammonium sulphate. The U.S. Government has assisted in developing the process, and two plants are now in operation, one at Irvington, N.J., producing 100 tons of "carbocoal" per day, and the other, at Clinchfield, Virginia, having a daily output capacity of 500 tons; the former has been working for two years and the latter since July, 1920. Over one hundred different kinds of coal have been successfully treated at Irvington, and although coals containing 30 to 35 per cent. of volatile matter are the best, quite inferior grades have been found to give satisfactory results.

Dr. Irvine Masson and Mr. T. L. McEwan contributed three papers on "The Recovery of Solvent Vapours from Air." In examining the processes of Brégeat and others, the authors have carried out a large number of determinations of the solubility of ether and alcohol vapours in cresol and other solvents. From the data obtained they have deduced a mathematical expression which correlates absorption with temperature and the vapour pressures of the solvents; and have shown how the results can be used to calculate the amount of liquid solvent and the number and dimensions of the absorption towers required in large-scale practice. The solvent vapours are best recovered from solution in cresol by steam distillation. Ether vapour may be absorbed with sulphuric acid of over 75 per cent. concentration, and recovered by distillation. Alcohol vapour is readily absorbed by this strength of sulphuric acid, and liberated by distillation after adding water to dilute the acid to 50 or 40 per cent. concentration. Cresol was found to be more efficient than sulphuric acid as a solvent for alcohol and ether, and by its use large quantities of these liquids were recovered during the war. The third paper dealt with the analysis of ether, alcohol and water mixtures.

PRESENT AND FUTURE POSITION OF THE CHEMICAL SOCIETIES OF GREAT BRITAIN.*

H. DROOP RICHMOND.

In 1914 the chemical societies were in a state of gentle activity, progressing slowly without any marked effort and reflecting the position of British chemical industry. The outbreak of war came as a sudden shock and revealed the facts that we had been dependent on other countries, notably Germany, for a very large portion of our chemical products, and had surrendered the position that we might have occupied. The reasons for this belong to the past, and any discussion of them opens such a wide question and has so little bearing on my subject that I simply record the fact; it is also a matter of recent history that British chemistry rose to the occasion, made up some of the leeway, and is now in the position it should have been many years ago. We have under the stress of necessity and at a great cost worked out for ourselves the fundamental principles of chemical manufacture of a large number of products which we did not make ourselves and have gained a knowledge which is approximating to that possessed by our competitors at the time when we commenced. We are not yet in a position to stand alone, for if we have learnt, so have they, and it will require more strenuous effort before we can compete in the world's markets.

The chemical societies helped in the national awakening, though under the conditions of stress the efforts made were largely individual and by groups, rather than by the chemists as an organised body; these conditions have ceased, and under the new circumstances we have time to work together to a common end, and the chemical societies can now take a large share in the advancement of British chemistry. Before the war there were four main bodies devoted entirely to chemistry:—The Chemical Society, for the advancement of pure chemistry; the Society of Chemical Industry, for that of applied chemistry; the Society of Public Analysts, for analytical chemistry; and the Institute of Chemistry, for the advancement of the profession of chemistry; and numerous other bodies, such as the Royal Society, the Royal Society of Arts, the British Association, and the Royal Institution, which promote the advancement of science including chemistry, and others, such as the Iron and Steel Institute, the Institute of Metals, the Biochemical Club, the Pharmaceutical Society, the British Pharmaceutical Conference, the Institute of Brewing, and many others which promote interests including more or less chemistry. Each society worked independently, though, partly from the fact that they had interests in common and partly because the prominent members of one body were often equally to the fore in the others, there was a certain amount of co-operation. The effect of the national crisis on the societies was, first of all, stagnation; then, as the outlook became clearer, the organisations of the societies were adapted to the national service, and each society has introduced changes to grapple with the altered economic conditions. It will be interesting to discuss those of the four purely chemical societies as indicating their present position.

The Chemical Society, which though localised in London is really a British society, has enlarged its scope to include the women chemists who helped to carry on during the war, and has initiated a scheme to render its library more generally available to all chemists.

The Society of Chemical Industry, which was the only body having local sections, has developed these and several new sections have sprung into being,

* Paper read before the Nottingham Section on November 24, 1920.

notably in the Dominions and has some claim to be an Empire society. At the same time it has developed its central organisation in London, where many matters are dealt with without reference to its Sections, and has started an innovation in society journalism by publishing an ephemeral review of current chemical topics. A chemical engineering group has been formed.

The Society of Public Analysts innovated a very useful section of "Notes" in its journal, but has not otherwise made any alteration. This body, though small and of restricted scope, is a British society and has always included a large proportion of provincial members on its council.

The Institute of Chemistry has undergone a remarkable change. Always a qualifying body, it has enlarged the scope of its qualifications very greatly, a very large number of members has been admitted without the examination formerly insisted on, and, curiously enough, at a time when a house primarily designed as an examination hall has been built has permanently relinquished a not inconsiderable proportion of its examination tests. Local sections have been started in many parts of the country, and these local sections have unofficially enlarged the scope of the activities of the society by discussing problems in chemistry as distinct from professional chemistry. It has started a Journal, an enlargement of the former Proceedings.

The enlargement of the activities of the Institute has been brought about by the formation of the British Association of Chemists, which threatened at first to engulf it, but which has now become a body primarily promoting the material interests of those chemists who are engaged in process and similar work. There is also the National Union of Chemical Workers, a trade union doing very useful work, and the British Association of Chemical Manufacturers, whose chief function is chemical policy, and the Federal Council has been formed to unite the whole of the societies for one common object.

The financial pinch has been felt by all the societies, and two years ago the Institute of Chemistry took the bold step of doubling its subscription to Fellows and students and increasing it by 50 per cent. to Associates; this step was not wholly brought about by war conditions, but was caused partly by the expiration of the lease just before the war and the greatly increased cost of the new premises; the increase was probably greater than was absolutely necessary, and gives a surplus devoted to increased activities.

The Society of Chemical Industry and the Chemical Society are now following suit with increases of 66 per cent. and 50 per cent. respectively, accompanied in the case of the latter by a 25 per cent. reduction in the entrance fee.

The Society of Public Analysts has not yet made any increase.

All the societies have made economies, the most noticeable being the suppression of the list of members usually issued annually, and the discontinuation of authors' copies by the Society of Chemical Industry, and generally each society has economised in minor matters.

The Chemical Society and the Society of Public Analysts have made few obvious failures, but in my opinion both the Institute of Chemistry and the Society of Chemical Industry are open to criticism. I have already stated my views before the Institute of Chemistry (*cf.* Proc. Inst. Chem., 1920, Vol. 2, p. 87), and in my opinion the Society of Chemical Industry spends too much on its central premises, and the Review portion of the Journal has not justified itself; as an ephemeral journal it appears with news too late and too trivial to meet the situation; the articles are often too weak, and it consists far too much of extracts from other papers on subjects not of great importance and interest to technical chemists. The greatest failure of all is common to the three societies that publish journals—the continual overlapping of matter published in chemistry.

British chemical science needs the societies, needs a journal of pure chemistry, a journal of technical chemistry and one of analytical chemistry, either combined with the technical journal or independent, a standard up-to-date lexicon of chemistry, a chemical directory, a complete and easily available chemical library, and an ephemeral journal. It has been suggested that the National Exchequer should be asked to provide funds for some or all of these objects, but apart from the public clamour against increased expenditure, it must be remembered that Government aid means Government control and red-tape, and I doubt whether the objects aimed at would not be hampered by this. The advancement of chemical knowledge has been the work of chemists in the past, and must remain so, and it is only chemists themselves who can do the work. We have managed to find the time and the money so far and must do so in the future; chemistry has been built by each man doing his bit and the more bits that each can do the less money is required, and there are many men who would do a bit or a larger bit if they could be fitted into the machine; as it is, many of us duplicate the work that others are doing.

I am a whole-hearted advocate of amalgamation; I see the greatest difficulties in bringing this about, but I do not see any that are unsurmountable if we all make up our minds. I think that the financial stringency is leading us to see more clearly that a fusion of interests makes for economy and avoids inefficient expenditure of our chemical resources; the avoidance of the duplication that now goes on will mean considerable saving in publishing expenses, our heaviest financial encumbrance.

All the societies are centralised in London, and it is doubtful if London has the same pre-eminence as the centre of chemical thought and industry as it has as the national capital, and I feel convinced that to centralise our chemical societies there results in a loss of chemical power which might be made available if the large provincial centres were to take a more active part. The Society of Chemical Industry and now the Institute have recognised this by local sections, which are in a very healthy state, and the Chemical Society and the Society of Public Analysts need the same organisation; chemists want opportunities to meet and thereby gather a wider outlook and see the problems in a different light. There is a tendency as a society grows to leave the routine work which was done in the early days by voluntary effort to salaried officials, and the more efficient the official the more he wants to do and the more important he tries to make his post; and as his view necessarily cannot be that of the members at large he will frequently branch off into spheres of activity which do not yield the best results to the members and which add to the expenditure. He is frequently supported by the older and more prosperous members of his council, who see the advantages partly from the point of view of their very capable official, and who are not obsessed with the constant idea of economy. The older men also have lost some of their pristine energy, and it will be to the advantage of the societies generally to have a proportion of young energetic men who will realise more truly than the leaders of the profession the needs of the members to leaven the ripe experience of the elder men.

Chemists have now fully come to the limit of what they can pay for the objects for which the societies were founded, and unless expenditure is watched carefully their work will not progress; they have not, however, yet come to the limit of the voluntary service they will give, especially if it is recompensed

not only by experience gained but in addition by "kudos." There has never been any lack of persons who will take the honorary appointments, and I doubt if any chemist seeks payment for the original articles published under his name, and I believe many members would undertake voluntarily the work of local correspondents, indexers, contributors to a lexicon or bibliographers if the opportunity were given them. Purely clerical work, which must be done on the spot, editorial and journalistic work at which the amateur cannot hope to vie with the professional, and advertising (which is a profession by itself) must obviously be paid for, but much more voluntary work can be done than at present.

Since I wrote this Sir William Pope has sent me a letter which the Federal Council has addressed to both the Chemical Society and Society of Chemical Industry, and has given me permission to make use of it. Of the six publications suggested, the first three are obvious, and the fifth is one that I have already advocated in an even more extended form; I would only advocate that an editor with full powers should be appointed, who should have complete control of the journals, and that the publication committee should act only as consultant on questions of policy, leaving questions of detail to the editorial staff. About the annual reports I am not quite so convinced. Those of the Society of Chemical Industry are not in sufficient demand to make them pay, and I think the question as to their necessity should be considered very carefully. Personally, I read them with a very great interest, but I make no practical use of them. As to the weekly journal, this must be run on journalistic lines by a chemist and journalist combined and would compete with existing journals. My opinion is that it would be better to enter into an arrangement with one or more of the weekly trade journals rather than fight them.

The letter referred to modifies the propositions that I intended to make, and therefore I propose: (1) That the Society of Chemical Industry should forthwith accept the invitation of the Federal Council and nominate a representative of each of the Sections to consider the publication question; (2) that the representatives be empowered to offer the sectional organisations to other societies with a view to giving provincial members a more active part in the advancement of chemical knowledge; (3) that until joint publication is adopted the Society should purge its journal of the weak matter now published, include far more of the sectional proceedings, and strengthen the Publication Committee by adding elected representatives of every Section.

THE BRITISH SCIENTIFIC GLASS INDUSTRY.

EDWARD QUINE.

The Committee on Commercial and Industrial Policy, under the chairmanship of Lord Balfour of Burleigh, in its Interim Report on Certain Essential Industries stated that:—"There are certain special commodities which are essential to national safety as being absolutely indispensable to important British industries, and were supplied before the war entirely or mainly from enemy sources or from sources under present enemy control"; and in submitting recommendations in connexion with these industries the Committee further stated that:—"A group of industries in the case of which very special treatment is necessary is that of the optical glass and instruments and the chemical and laboratory glassware trades. The types of manufacture dealt with lie in the higher grades of the glass industry. To be successful they require specially skilled operatives and a direction not only commercial but possessing considerable scientific attainments. They carry meagre possibilities in direct profits, and as a result have not hitherto interested manufacturers in a degree in any sense commensurate with their importance in the industrial progress of the nation. Although comparatively small as regards the amount of capital required to be invested and of the labour employed therein, these industries are of vital national importance both on naval and military grounds and for all purposes of applied science and scientific research."

Optical Glass and Scientific Instruments.—Prior to the work of Schott and Abbe, a large portion of the optical glass required by British scientific instrument makers was made in the country, but the impetus and lead given by the researches of those scientists, which were supported by the Prussian Government, placed the German optical glass industry in such a commanding position that in 1914 only Messrs. Chance Bros., of Smethwick, were manufacturing optical glass in this country, and 80 per cent. of the optical glass used by British instrument makers, whose production was exceedingly small, was supplied by Germany.

The dependence of the safety of the nation upon the production of optical glass is clearly evident when it is appreciated that upon such glass depends the supply of range-finders, directors for artillery dial sights, gun sights, telescopes and binoculars, aeroplane-sighting and photographic instruments, trench and submarine periscopes.

Our position at the commencement of the war was truly alarming, and our armies took the field seriously handicapped owing to the predominance of our enemies in all instruments which may be termed the "eyes of the army."

During the war, although handicapped by shortage of skilled labour, by lack of materials, and by lack of knowledge of the manufacture of certain types of optical glass, British manufacturers and scientists laboured so successfully that before its termination practically every requirement of the scientific instrument maker, whether his products were required for the Forces or the laboratory, could be met by British optical glass.

To-day England can supply optical glass to meet all requirements of the British Empire in addition to those of foreign countries, and is producing certain types of optical glasses superior to those made in any other part of the world. The credit of this achievement is mainly due to the efforts and sacrifices of Messrs. Chance Bros., Messrs. Derby Crown Glass Co., Ltd., the late Mr. A. S. Esslemont, Sir Herbert Jaskson, and Dr. C. J. Peddle.

Chemical and Laboratory Glassware.—Chemical and laboratory glassware is that glassware which is used in laboratories for scientific purposes, and may be divided into two main classes:—(1) Hollow glassware, which is mainly manufactured at the glass furnace, *e.g.*, flasks, beakers, petri dishes, etc. (2) articles of glassware which are made mainly from tubing at the blow-lamp flame, *e.g.*, thermometers, pipettes, X-ray tubes, etc.

It will be readily appreciated that the dyestuff, steel, chemical, explosive, gas, and metal industries require an adequate production of scientific glassware, as do also medical and research laboratories attached to hospitals, county and municipal laboratories devoted to public health and hygiene, and the various laboratories at universities, colleges, etc.; in fact, it may be fairly claimed that the scientific glass industry both in times of peace and war is the master "key" industry.

This industry was almost entirely in the hands

Germany and Austria before the war, and practically the whole of the hollow-blown furnace-made glassware was obtained from these countries. It is almost equally true that the entire lamp-blown scientific glassware was obtained from foreign countries, although there existed in this country a small number of highly skilled workers at the blow-lamp flame who produced the unrivalled English clinical thermometer and a limited number of types of chemical thermometers. In addition to these workers, there was a number of lamp workers who repaired damaged foreign glass apparatus, produced special lamp-blown glass apparatus, and tided over the difficulties of importers awaiting shipment of foreign-made glassware. These highly skilled glass workers could almost be counted on the fingers and belonged to the industrial class covered by the term "out-workers," whose premises were unpretentious and whose capital and apparatus were limited to a few pounds and a blow-lamp. It was fortunate that the dealers in laboratory glassware had large stocks when war broke out; otherwise the production of munitions would probably have come to a very sharp end, and it was soon apparent to those familiar with this industry that should the war be a long one the situation would become exceedingly critical. Steps were taken to produce scientific glassware in this country, but this was an exceedingly difficult task, for though it was possible for the chemist to analyse glassware and evolve formulæ, the commercial manufacture of the glass presented enormous technical difficulties. With no previous experience of this industry to guide them except that of the domestic glassware and the bottle industry, our glass manufacturers tackled the problems. In their endeavours they met with reverse after reverse, for, apart from a lack of knowledge, inadequate materials and glasshouse equipment, there was no British labour trained to blow the light hollow ware required in laboratories. Stocks rapidly diminished, manufacturers were pressed for their production, and British-made scientific glassware was placed on the market in a condition which was as unsatisfactory to the manufacturers as to the users, and could only be termed "stop-gap." Steadily, however, and at the cost of great monetary loss, the production of scientific glassware was improved, and to-day our manufacturers are producing light hollow-blown scientific glassware which is superior in resistance to chemical reagents, and general utility, to that produced in any other country.

The lamp-blown section of the industry is dependent upon an adequate supply of glass tubing, and before the war there were few skilled tube-drawers in this country, and although efforts were made to train workers, this was an undertaking requiring time, for the operation is one requiring great physical endurance and manipulative skill; and in spite of exceedingly high wages, even at the close of the war the number of skilled tube-drawers in this country was lamentably small.

The skill required of the operator who manufactures a lamp-blown article from tubing varies from that required to make a simple article, such as an ampoule, to that required for making a high-grade thermometer or X-ray tube, and it was therefore possible to increase rapidly the number of workers engaged in the simpler operations; but the high degree of skill required, together with the demands of the recruiting authorities, prevented any large increase in the numbers of the highly skilled workers. Yet on this weak section of the industry, struggling against innumerable difficulties due to lack of adequate glass tubing, lack of manufacturing plant and lack of skilled labour, was thrown at one critical period of the war a responsibility in connexion with our anti-submarine campaign on the satisfactory discharge of which our national safety depended; and the glass-tube drawers and lamp-workers did not fail.

The demand for scientific glassware in the future will exceed that in the past, for it is obvious that the industrial progress and health of a community is becoming increasingly dependent upon its laboratories. Our Empire cannot afford to allow its industries, its health, and its safety in time of war to be dependent upon a commodity, the manufacture of which is controlled by a foreign nation.

We are, however, swiftly drifting into that position, for, owing to the difficulties experienced by manufacturers in developing the scientific glass industry, the high costs of building and equipment, and the strength and reputation of the German and Austrian manufacturers, the industry was never in a position to stand unaided against continental competition, and the rate of exchange has now made the position, without protection, hopeless.

The Standing Committee on Trusts, in its interim report just issued, says:—"The manufacturers of scientific glassware have incurred considerable losses since they undertook to manufacture this class of glassware, and although we are not able to report as to the fairness or unfairness of past and present prices, we consider that such temporary support should be afforded to this new industry as is consistent with fairness to consumers. If this were done, probably within reasonable time the industry would be able both to hold its own against foreign competition and to sell its productions at prices acceptable to the public."

Unrestricted importation of scientific glassware, however, is to-day crushing the British industry, and some manufacturers have been forced to cease production, others have discharged labour trained at great expense in the time of the nation's need, and soon, unless help in the way of preventing unfair continental competition is given, the industry will pass to Germany and Austria, and once more the Empire will depend upon our late enemies for that production which is most essential to our industrial progress and national safety.

REPORT OF THE RAILWAY RATES ADVISORY COMMITTEE.

A. J. MALACRIDA.
(Transport Manager, Association of British Chemical Manufacturers.)

The Railway Rates Advisory Committee after sitting in public for forty days has now presented to the Minister of Transport its report (Cmd. 1098, 9d.) on the principles which should govern the fixing of tolls, rates and charges for the carriage of merchandise by freight and passenger train and by other services. As the report is very comprehensive, consisting of 54 foolscap pages, it is not possible to consider all the important points it raises, but as many of the proposals are of vital importance to the chemical industry, it is essential that these should be treated at some length.

The two main principles advocated by the Committee in respect of the fixing of future rates are:—

(1) The charge must in no case be less than the cost to the railway company of rendering the required services.

(2) The charge must in no case be more than the value of the services to the trader.

This seems a very sound policy, especially so far as the chemical industry is concerned, because at the present time the rates which are charged for the conveyance of chemical commodities are out of all proportion to the cost to the railway companies and

to the value of the service to the trader. It is not necessary to labour this point because it has already been fully dealt with in the articles which have appeared in previous issues of this *Journal*, by Mr. J. Lukes, traffic manager to Messrs. Brotherton and Co., Ltd.

In regard to the component parts of the new rates, the report states that all parties seem to be agreed that the present system should be continued, *i.e.*, there should be a rate for conveyance and separate rates for station accommodation and services rendered at the terminals at each end of the transit, and that owners of private sidings should only be charged for the services actually rendered to them, the proper rates being fixed for terminal charges at the same time as the conveyance rates. The Rates Advisory Committee recommends that a new tribunal should be set up to deal with the fixing of the rates, tolls and charges, and to the present writer this appears to be a great step forward, which should prove of much benefit to the trading community as a whole. At the present time the fixing of rates and charges is left entirely in the hands of the railway companies, so long as they do not exceed their maximum power and do not create undue preference in favour of one trader as against another. Apart from this the trader has no voice in the fixing of the rates and charges, and the recommendation now made should assist in the development of industry generally. To illustrate this one might instance many cases in which representations have been made to the railway companies that certain commodities could not bear the rates charged between particular points, and in which the companies have refused to grant reductions on the ground that although the traffic would not pass between the particular points in which a trader was interested, it would pass in other directions. In future, cases of this sort would be brought before the new tribunal, which would doubtless consider them from all points of view, and in all probability it would grant such rates as would enable traffic to move freely; and whilst perhaps the rate might be on a lower basis than the railways would usually approve, it might still be remunerative, having regard to the possibility of developing the industry and increasing the traffic put on the railways.

From the standpoint of the chemical industry, the most important feature of the suggested tribunal is that it would decide as to which articles are to be classed as "dangerous goods." The wording of the recommendation is perhaps not quite as clear as the industry would desire, yet it is thought that the suggestion is a great advance on the existing position. It is well known that at the present time the railway companies have absolute power under Section 105 of the Railway Clauses Consolidation Act, 1845, to specify which goods are dangerous, and this decision, if based on the *bona fide* judgment of the railways that the goods are dangerous, cannot be altered except by a repeal of the Statute. This is aptly illustrated in the case of *The Midland Railway and Others* v. *Messrs. Butler and Co. (Bristol), Ltd., and Messrs. Brotherton and Co., Ltd.*, in which the Railway and Canal Commissioners held that they could not alter the *bona fide* judgment of the railway company that certain goods were of a dangerous nature.

In addition to the new tribunal, the Rates Advisory Committee recommends that a body, to be called the Railway and Traders' Conference, should be set up to act as a Conciliation Board without coercive powers. The proposal is that in each of the great distributing centres of the country two panels should be set up, one consisting of representative traders, and the other of officials of the railway companies serving the district; and that from these panels a committee should be formed to which any traders having a grievance might make application, and which would have power to make recommendations but not to make or enforce orders. If a question appeared to involve general principles or an issue of great importance, the local tribunal would be empowered to refer it to the Rates Fixing Tribunal. The object of these local tribunals is to secure a hearing for traders who, although admitting that the railway authorities will usually redress a grievance if it be properly presented to them, nevertheless contend that their complaints are too often disposed of in a rough and ready manner by minor officials without adequate consideration.

Maximum and Actual Rates.—The maximum charges for the conveyance of merchandise which the railway companies are entitled to make under the Rates and Charges Order Confirmation Acts, 1891-92, were really a necessity so long as the railways were allowed to determine the actual rate, but as the power to fix rates is in future to be in the hands of the new tribunal, the Rates Advisory Committee suggests that it should also be entrusted with the determination of maximum rates. This appears very reasonable, seeing that the new tribunal is to have the power of raising or lowering rates after full investigation.

Continuous Mileage.—Throughout the evidence given by the traders, a general desire was expressed that the new system of fixing rates should be on the principle of continuous mileage, and not upon the cumulative principle now in operation. The effect of the cumulative principle is that rates for a distance of, say, 100 miles, when computed over two lines of railway, are greater than those for 100 miles when the transit is on one line of railway only; and the Rates Advisory Committee considers this state of things to be a serious anomaly. The railway companies strongly opposed the principle of continuous mileage, although actually many of the rates which they charge at the present time are based upon it, as are also, generally speaking, the receipts for the conveyance of merchandise when divided between the various railways, no regard being paid to any advantage that may have accrued where the rates are made upon the cumulative principle. The Rates Advisory Committee therefore recommends that in the case of through rates the principle of continuous mileage be adopted with provisions in the case of different rates prevailing on the railways involved similar to those in regard to portions of the railway having different maxima under the Railway Rates and Charges Orders.

One of the most important features of the recommendation relating to continuous mileage is its application to short distance traffic and to the fixing of the minimum charge. The report states:—"We consider the anomaly of making two minimum charges as for six miles each of transit, for possibly a total distance of four or five miles, as more objectionable than that of different charges for long-distance hauls according to whether the transit is on one or more railways." With the adoption of continuous mileage, the Rates Advisory Committee does not intend to interfere with the existing regulations, but to allow bonus mileage to be charged in respect of the portions of the lines which have been constructed at extraordinary expense, such as Runcorn Bridge, Forth Bridge, Severn Tunnel and lines in and around London. It is intended that such bonuses should continue to be charged, and in general indicated by the total distance being treated as being increased by the stipulated extra mileage. In those cases where different maxima have been fixed in respect of certain portions of the same railway, the Committee thinks that these differences should not be continued, but that a single rate sufficient to provide the desired revenue should be fixed for each class of

goods upon the whole or each of the railways or groups.

Terminals and Disintegration of Rates.—Section 33, Sub-section 3, of the Railway and Canal Traffic Act, 1888, placed an obligation upon the railway companies to disintegrate rates when application is made by a trader, but the disintegrations which have been given by the companies in the past have been in such a form as to be practically useless to the trader asking for the information; and during the hearing the traders consistently urged that all rates in future should be disintegrated in such a manner as to show separately the difference between the amounts for conveyance and those for each of the services.

The railway companies are willing to concede that if standard rates and tariff are fixed by an independent authority, the rates and tariff so fixed should show the amounts to be charged for conveyance and for terminal accommodation and services separately, but they claim that there should be no obligation upon them to disintegrate exceptional rates or apportion any part of the charge to terminals. The Committee is of the opinion that there is "to some extent justice in the claims of the traders, but that the counter arguments of the railway companies ought not to be ignored," and it recommends that the conveyance rate and terminal charges should be separately specified in the standard rates to be fixed by the tribunal, and that when the tribunal is called upon to fix an exceptional rate it should specify how much of that rate is for conveyance and how much for each terminal.

In the main, the claims urged by the traders have been met in the recommendations of the Committee, and these will prove a great boon, especially to those traders whose works are connected with the railways by private sidings.

Services Rendered at or in connexion with Private Sidings.—The present position as regards private sidings is that the owner pays the conveyance rate, but is free from any general obligation to pay the terminal charges whether for station accommodation or services, but the Rates and Charges Order Confirmation Acts, 1891-92, provide that the railway companies may charge a reasonable sum for services rendered at or in connexion with traffic at sidings not belonging to the company, any difference arising under Section 5 of the Orders quoted to be determinable by an arbitrator appointed by the Board of Trade. In practice, however, the railways have made their charge for siding services the amount of the terminal charges that are included in the rate applicable to the nearest goods station. This may be the full statutory terminal charges or less, according to the amount of the rate charged.

Whilst the Rates Advisory Committee does not see any reason for altering this state of things, it recommends that the duty of determining any difference should be placed upon the new tribunal. With a view, however, to fixing the reasonable sum to be paid by the owner of a private siding during any period which may elapse before the question can be determined, either by an agreement or by a new tribunal, the Committee has framed a series of rules.

Other matters dealt with in the report are "Conditions Affecting Carriage by Rail," and the "Conveyance of Traffic at the Actual Gross Weight" (except in the case of timber).

The report, as a whole, is a very valuable document, and opens the way for a scheme whereby the railway rates of the future may be made very much simpler and therefore more helpful to all concerned. The traders have gained valuable concessions, which will doubtless be more appreciated as their effects come to be experienced.

CORRESPONDENCE.

RAIL CONVEYANCE OF CHEMICAL COMMODITIES.

Sir,—Mr. Lukes' article in the *Journal* of December 31 does not, I think, need a lengthy reply from me, and I would ask those who are interested in the subject to re-read my article in the *Journal* of November 15, and they can judge whether I succeeded in correcting the exaggerations in Mr. Lukes' first article, and whether he has now brought forward any new facts of material importance.

When Mr. Lukes asserts that the railway companies have the power to decide what goods are dangerous and the sum to be charged for their conveyance "whether their views be right or wrong," he exaggerates the facts. The law provides that the companies shall not exercise their powers unjustly, and their charges must be reasonable.

The quotation from the American Inter-State Commerce Commission Regulations appears to insinuate that the British railway companies have not conferred with manufacturers and shippers in regard to specifications and regulations for the packing and transport of dangerous goods, but Mr. Lukes knows that many such conferences have been held and amendments made as the result of such discussions. I do not know whether these conferences are compulsory in America, but I do know that the British railways are not compelled to hold such conferences, but have done so *voluntarily*.

In his reference to the test case heard before the Railway and Canal Commissioners, in the matter of the *North-Eastern Railway Co.* v. *Reckitt and Sons, Ltd.*, Mr. Lukes omits to mention that the presiding judge, Mr. Justice Bankes, stated in delivering his judgment:—"In my opinion, therefore, even if the test contended for by the defendants be applied, these goods are dangerous." Mr. Gathorne Hardy, although in some doubt, said:—"On the whole, especially having regard to the question of storing and warehousing, I cannot bring my mind to the conclusion that these are not dangerous goods." Sir James Woodhouse, although he held a different opinion, as stated by Mr. Lukes, made some very pertinent remarks which Mr. Lukes omits from his quotation. Sir James said, in reference to Section 105 of the Railway Clauses Act, 1845, and the companies' powers:—"*They must of course exercise the discretion vested in them with absolutely good faith and not for the indirect purpose of obtaining charges which they could not otherwise obtain. There is no suggestion of their acting otherwise in this case.*" (The italics are mine.) Mr. Lukes complains of the arbitrary powers given to the railway companies, but he has not given a single instance in which the Court has decided that these powers have been used by the companies in an unfair and arbitrary manner.

I stated in my article that the rates charged for dangerous goods had not been *generally* raised as a consequence of their transference from the White to the Yellow pages. Mr. Lukes gives no instance to the contrary. He mentions trinitrotoluol; but this substance always has been classified as a dangerous article, and the change made has been to transfer it from the category of Dangerous Chemicals to the list of Explosives, consequent upon the issue of an Order-in-Council, No. 898 of 1917, which definitely included it in the Authorised List. The rates charged for its conveyance automatically became the same as those charged for all other explosives of the same class.

As regards "Spirits of Tar" and "Mineral Tar Oil," no rates were raised. In these cases, the traders claimed to declare their traffics under names which did not correctly describe them, in order to

obtain the benefit of lower rates, but the Court decided that these claims could not be upheld.

Private-siding rates and the contention that all railway rates should be based upon the actual cost and the capital actually employed in handling and conveyance of the particular traffic involved have been dealt with in the report of the Rates Advisory Committee recently issued by the Ministry of Transport, and no further word need be said here. This report also deals with the classification of dangerous goods, the railway companies' liability in connexion with them, the rates to be charged, and the indemnity against consequences. One clear statement in the report may be quoted which has been urged over and over again but never accepted by some traders or their representatives. It occurs on p. 10, and is as follows:—" But as soon as it is established that rates are from time to time to be so fixed that the railway companies (subject to the obligation of providing good management) are secure of receiving adequate net revenue, they have a much smaller concern in the question of lowering particular rates or classes of rates, being satisfied that the aggregate will be made good to them from some other source, while the traders generally have become deeply interested parties to the discussion, seeing that for the first time wherever a diminution of revenue is caused by concessions to one class it will have to be made good by throwing the burden to the rest of their body. In other words, whenever a proposal is made in the general revision of rates for favourable treatment for any class of commodities the general body of traders have a greater interest in opposing it than have the railway companies. Indeed, but for the fact that the knowledge and experience of the railway companies' officials are necessary to secure a scheme that will work smoothly and efficiently, those companies might stand on one side and say: 'Let the traders decide among themselves how they desire that the necessary revenue should be raised.' " May we hope that now that this truth has been pronounced by the " impartial business tribunal " appointed by the Ministry, on which there was only one railway representative, after an exhaustive inquiry, it will be accepted, and that the agitation founded on other ideas will cease?

In concluding these remarks, I again acknowledge with thanks the valuable assistance of some of my railway colleagues.—I am, Sir, etc.,

L. Archbutt.

MEETINGS OF OTHER SOCIETIES.

ROYAL SOCIETY OF ARTS.

Three Cantor Lectures on " Micro-organisms and some of their Industrial Uses " were delivered on November 29, December 13 and 20, by Mr. A. Chaston Chapman, Dr. M. O. Forster presiding.

Commencing with the discovery of zymase by Büchner, the lecturer briefly described Harden's work on the enzymic nature of fermentation, showing that the presence of a co-enzyme was as necessary as that of the zymase itself. The mechanism of alcoholic fermentation was then dealt with at some length, and it was shown that pyruvic acid and acetaldehyde were intermediate products formed during the fermentation of sugar under certain conditions.

The importance, from the point of view of chemical industry, of being able to modify cell-functions by varying their environmental conditions was indicated and illustrated by several examples. The production of glycerin on a large scale during the war by the fermentation of sugar was described and the results obtained in Germany and in the United States were referred to.

The Amylo process for the production of alcohol on the large scale was next dealt with somewhat fully, and the nature of the improvements in the process made during recent years and the directions in which further improvements might be looked for were indicated. It was pointed out that about 20 million hectolitres of absolute alcohol had been made on the Continent by this process since its introduction, twenty years ago, but that, owing to excise restrictions, it could not be employed in this country. The use of bacteria for liquefying starch in the Amylo process for the purpose of reducing the waste of nitrogen was also described.

Further illustrations of the technical application of microbiology to industrial chemistry were instanced in the manufacture of citric, pyruvic, and fumaric acids by so-called " fermentation " processes. The manufacture of lactic acid was somewhat fully described, and the lecturer pointed out the unprogressive character of the industry in this country, the technical conditions to-day being but little better than at the commencement. The manufacture of butyric acid was stated to be in an even worse position, as the best and most economical conditions for the biochemical production of this acid were far from being known. The manufacture of vinegar was next described, and it was pointed out that, although the industry is worked on sound lines—so far as the preparation of the alcoholic wash is concerned—it is on a much less satisfactory basis on the biological side. The working losses experienced at present are often very considerable, and most manufacturers have little or no knowledge of the actual biological character of the organism or organisms they are using.

At the commencement of the third lecture the biochemical production of butyl alcohol and acetone from starchy materials was dealt with, and reference was made to the results obtained during the war at King's Lynn, at H.M. Naval Cordite Factory at Holton Heath, and at the works of the British Acetone Co. at Toronto (cf. J., 1919, 271 T, 273 T, 282 T, 411 T). The mechanism of the process is very complex, and in order that it might compete with the ordinary process for the production of acetone, cheap raw material must be available, as well as a market for the butyl alcohol, the hydrogen formed and the constituents of the spent wash. The conversion of butyl alcohol into methylethylketone was a possible solution of one of the above problems.

The lecturer then referred to the use of certain of the lower fungi for the production of nitrogenous foodstuffs. Brewers' yeast constitutes a valuable cattle food or, when de-bittered, can also be used as a constituent of manufactured food products intended for human consumption. The use of yeast for the manufacture of an extract closely resembling extract of meat in its chemical and physical properties was referred to, and it was mentioned that a well-known brand of yeast-extract at present on the market had been found to be rich in the water-soluble vitamine or accessory growth substance, whilst meat extract had been found to be devoid of this important growth-promoting constituent.

The use, for food purposes, of the so-called " mineral yeast " in Germany during the war and its manufacture in this country were described (cf. J., 1919, 285 T). The discovery of a simple biochemical method for the conversion of cellulose into sugar was mentioned as affording a probable solution of the power alcohol problem and also of rendering possible the economical production of synthetic nitrogenous foodstuffs.

In conclusion, Mr. Chaston Chapman pointed out how backward England had been in connexion with important discoveries in the domain of industrial

microbiology, and renewed his plea for the foundation of a National Institute devoted to that subject (*cf.* J., 1919, 282R). The function of such an institute would be to provide for the systematic prosecution of research in connexion with all those industries in which micro-organisms or enzymes play an important part. In addition to this it would serve as a centre for the specialised training of men intending to devote themselves to the teaching of microbiology and biochemistry in our universities and technical schools, as well as for the practical instruction of technical employees engaged in the various biochemical industries. It would also provide breweries, distilleries, and other factories with any required organisms in pure culture, and would serve generally as a central home for the promotion of microbiological science.

NEWS AND NOTES.

SOUTH AFRICA.

Lead and Vanadium in the Transvaal.—A deposit of lead and vanadium, probably of considerable extent, with a content of lead metal ranging from 8·15 to 15·5 per cent., and of vanadium pentoxide from a trace to 1·35 per cent., occurs at the old Doornhoek Lead Mine, Marico District.—(*S. Afr. J. Ind., Nov.*, 1920.)

Maroola Nuts as a Source of Oil.—A sample of Maroola nuts (*Sclerocarya caffra*—a tree that occurs extensively in the Transvaal), has been investigated at the Imperial Institute, which reports that the nuts consist of about 90 per cent. of shell (very tough and fibrous), and only about 10 per cent. of kernel. The kernels yielded 59·2 per cent. (dry basis) of a non-drying oil which would be suitable for soap manufacture and possibly for edible purposes. It is very improbable that the nuts could be used as a source of oil owing to the difficulty with which they are cracked and the kernels separated.—(*S. Afr. J. Ind., Nov.*, 1920.)

Platinum in the Lydenburg District.—Pending reliable information concerning the alleged important discovery of platinum in the Cala district, it may be recalled that this metal is known to occur in other parts of the Union. Pseudo-stratified segregations of chromite associated with platinum occur for considerable distances along the margin of the Bushveld granite area in the Transvaal. The segregations are several inches thick, and though of workable size and extent have never been exploited. The chromic-oxide content is usually between 35—45 per cent., but 54 per cent. in places, and the Mines Department of the Union states that the ores contain an appreciable quantity of platinum. Platinum and allied metals are also found in the black sands derived from the conglomerates in the Klerksdorp area, a district which is at present very inaccessible, but the occurrence is stated to be well worth attention.—(*Official.*)

Sulphur in South Africa.—The imports of sulphur into the Union of South Africa during 1913 and 1917 were as follows:—

	1913.	1917.
Sulphur (long tons) ...	2672 ...	899
Pyrites („) ...	22,903 ...	18,465
Sulphuric acid (lb.) ...	291,976 ...	37,435

Five factories in the country produce sulphuric acid for their own use, and for trade when supplies of pyrites and railway facilities are available. The present demand for pyrites amounts to 1650 tons per month; shortly it may be 3500 tons. Deposits of native sulphur are known to occur in the Union, but none of these, so far as is known, could be profitably worked. Railway facilities are needed for the development of the massive pyrites deposits occurring in the Areachap Copper Mine, 10 miles from the station. Disseminated pyrites is plentiful in the gold-bearing rocks and in the coal mines. It is estimated that during next year coking plants in the Union will supply about 450 tons of pyrites per month. Pyritic auriferous concentrates, derived from the Sandstone Reef, afforded a monthly supply of 400 tons of pyrites in 1919, and it is thought that supplies from this source can be increased to 1000 tons. The remaining requirements of the Union may possibly be met by the utilisation of pyrites derived from concentrates produced in the Barberton district; the presence of arsenic, to the extent of about 1 per cent., has hitherto hindered their exploitation.—(*S. Afr. J. Ind., Nov.*, 1920.)

AUSTRALIA.

Yacca Gum in South Australia.—The collection and export of yacca gum was an important industry in Kangaroo Island, South Australia, prior to 1914, but operations were suspended during the early years of the war as the chief market, Germany, was closed. A revival, however, took place in 1916, and in 1919 over 10,000 tons was collected, most of which was exported to Great Britain and the United States. The gum is soluble in alcohol and caustic alkalis, but insoluble in turpentine, linseed oil, benzine, and hydrocarbon solvents generally; it is stated to be serviceable in the manufacture of photographic chemicals, dyestuffs, and linoleum (*cf.* J., 1918, 392 R).—(*U.S. Com. Rep., Nov.* 19, 1920.)

NEW ZEALAND.

Mining and Minerals in 1919.—The Mines Statement for 1919, by the New Zealand Minister of Mines records that legislation will shortly be introduced to revive the bonus provisions of the Iron and Steel Industries Act, 1914, and that arrangements are being made to have 20 tons of iron sand from Taranaki and 20 tons of iron ore from Parapara tested in England by a new process in order to determine if it is possible to produce iron on a commercial scale in New Zealand. Since September, 1919, the Government has been negotiating with the British Admiralty with a view to making an arrangement with the British Government for boring and developing mineral oil and other products in New Zealand, but no agreement has yet been made. Unfortunately, petroleum has yet not been found in payable quantity in New Zealand, but the Government is now taking steps to settle definitely whether the oil resources are of commercial value.

During the year 1919 gold to the value of £573,662 was obtained from quartz mines, 286,073 tons of ore being treated; the value from alluvial and dredge mining was £128,111. There was practically no demand for tungsten ore (scheelite) for the English market; the price fell from 68s. to 30s. per unit, and consequently the production was very small—131 tons, compared with 169·5 t. in 1918. The mining of cinnabar and production of mercury were carried out by one company, and 11,175 lb. of metal was produced. The Mines Department is assisting the company to test the lode on its property, and improved returns are looked for in the near future. The quantity of phosphate rock quarried was 4000 t., as against 5000 t. in 1918. The coal output was 1,847,848 t., compared with 2,034,250 t. in 1918, the decrease being due to organised restriction of work by the miners on several fields. The production of kauri gum rose from 2419 t., valued at £157,313, in 1918, to 4128 t., worth £255,812, in 1919. A company with a capital of £200,000 has been formed to produce oil and gum from kauri peat, of which it possesses some

6¼ million cb. yds. on its properties. As the yield is estimated to be £1's worth of fine gum per cb. yd. of peat, a large production is anticipated.

UNITED STATES.

Coloured Plasters.—The production of coloured plasters has been made possible by simply mixing dyed wood fibres with gypsum. A series of samples has been made and tested by the U.S. Bureau of Standards.

Charcoal from Walnut Shells.—Experiments made in California appear to have overcome the difficulty attending the retorting or charring of dusty cellulosic materials such as walnut shells. The ground shells are passed through the hot zone of a flame which completely burns off the dust, baffles and lifters ensure adequate mixing, tar is recovered from the exit gases, and the resulting charcoal is quenched as it is discharged from the kiln. The walnut-shell charcoal is used instead of willow charcoal for poultry.

Use of Cyanamide and Superphosphate Mixtures as Fertiliser.—The toxic effects on plant life due to the application of cyanamide mixed with superphosphate are now reported to be caused by the rapid formation of dicyanodiamide. Conversion of cyanamide into dicyanodiamide by moisture is much accelerated in the presence of superphosphate; calcined and basic phosphates exert no action. The use of a dry mixture is of little avail as the soil moisture may bring about the change under certain conditions.

Lime in 1918.—The total quantity of hydrated lime produced in 1918 was 620,216 short tons, valued at $5,342,513, and the total quantity of lime sold amounted to 3,206,016 short tons valued at $26,808,909, an average price of $8·36 per ton. The building trade consumed 28·5 per cent., chemical works absorbed 17·7, and agriculture used 12·2 per cent. of the total production. Imports amounted to 6650 t. and exports to 7191 t.

At least five companies used lignite as fuel, one producer reporting that it compared favourably with other fuels, both in regard to cost and the quality of lime produced. A lignite containing a large percentage of moisture produces a soft-burned lime similar to lime burned with wood. It usually requires about half a ton of lignite to burn a ton of lime. To be used efficiently the kiln should have a fire-box with large grate area and a high arch or combustion chamber; it should also have a taller shaft than usual since the gases in lignite distil off very rapidly and would otherwise burn off on the top of the kiln. After storing lignite a week or two, it will produce only about half the quantity of lime it does when fresh.—(*U.S. Geol. Surv., June* 7, 1920.)

JAPAN.

Opium Production.—The production of opium in Japan has made very great strides during the past few years, as the following official statistics show:—1913, 2196 cwt.; 1914, 2877 cwt.; 1915, 7516 cwt.; 1916, 22,774 cwt.; 1917, 28,792 cwt.; 1918, 10,123 cwt.; 1919, 33,731·5 cwt. During 1919 the poppy was cultivated in thirty Prefectures of which Osaka, Wakamaya, Hojogo, Yamayachi, and Seitana were the chief. The average morphine content of the 1919 crop was 12·68 per cent., which was 3 per cent. lower than that of the crop in 1918.—(*Chem. Ind., Dec.* 15, 1920.)

The Cement Industry.—The Japanese cement industry is in a flourishing condition; the formation of several new companies is announced, and most of the existing companies have extended their activities. The combined paid-up capital of twelve old-established firms increased from £3,200,000 in 1914 to £4,460,000 in 1919, and the price of cement rose from 6s. 1½d. per 400 lb. to more than four times that amount during the same period; similarly, the production increased from 3,625,000 to 6,500,000 barrels, and the exports from 258,000 to 997,000 barrels.—(*Bull. Dept. Tr. and Com.*, Nov. 22, 1920.)

"Koka Seki" Pumice.—"Koka seki" is a variety of pumice stone found only in the Niijima Islands, about 90 miles south of Tokyo. It has long been used as a building material, and on account of its durability, high tensile strength, and resistance to heat (1300° C.), it can be used in boilers and furnaces as well as for lining safes and refrigerators. Its most important use is in the construction of reinforced concrete barges. The concrete is stated to be about 60 per cent. lighter than the ordinary kind, and to be absolutely resistant to seepage, erosion, etc. "Koka seki" has recently been selling in Japan at about 2s. per cb. ft. for blocks and 8d. per cb. ft. for flakes and sand.—(*U. S. Com. Rep., Oct.* 26, 1920.)

FRANCE.

Industrial Notes.—*Coal.*—The high costs of coal and labour, together with shortened hours of work, are responsible for the continuance of the industrial crisis. The economic situation has been seriously affected by the excess of supply over demand, imports having exceeded exports and Allied war stocks having been released. The high cost of coal in particular is a serious handicap, for the price is in France very much higher than in any of the neighbouring countries, and manufacturers are therefore unable to cope with foreign competition. The remedy suggested is not a high tariff wall, but compensatory duties to equalise the production costs to competitors. The decontrol of the coal industry is being considered by the Minister of Public Works and the Coal Commission has been instructed to prepare a scheme to ensure supplies until decontrol is complete. The output of coal in October was 2,250,880 tons, and of lignite 85,585 t., whilst 846,629 t. was produced in the Saar basin. Germany exported 1,814,864 t. during November, of which 1,242,974 t. went to France. Imports of American coal continue to increase; in January, 1920, 20,000 t. was imported at $30–32 per ton, and in November, 1920, 700,000 t. at $15–16 per ton.

Chemical Industry.—The formation of large chemical trusts in the United States, in Great Britain, and, to some extent, in France, is being criticised on the ground that such combinations tend to develop bureaucratic methods and thus lead to inefficiency. The critics would prefer a system of agreements between producers under which each would specialise in certain products and supply prescribed areas. Such a system, they say, leaves to each partner his own responsibilities and interests, but allows him to reap the advantages accruing from concerted action.

Great progress is being made by the Société des Matières Colorantes et Produits Chimiques de St. Denis, which extended its works in 1919 with a view to producing all the raw materials and intermediates required in dyestuff manufacture. In June, 1920, it was producing coal-tar intermediates and dyes at the rate of 135 and 150 tons a month, respectively, and as soon as certain extensions are completed, these figures will be more than trebled, thus allowing an ample margin for export.

The Société de la Grande Paroisse intends to erect at Montereau a synthetic nitrogen plant (Claude process) with a daily capacity of five tons of liquid ammonia, and the Société Norvègienne de l'Azole is to extend its nitrogen works at Soulom.

Metallurgy.—The demand for metallurgical products is very small in view of the expected decline in prices. It is unlikely, however, that prices will fall to any extent until the large stocks

of foreign coal bought at high prices have been liquidated. The reported agreement between French, Belgian, and Luxembourg producers of cast iron with a view to stabilising prices has not been ratified.

GENERAL.

Chaulmoogra Oil.—In a recent number of the *Journal of Tropical Medicine and Hygiene*, Dr. T. A. Henry, Director of the Wellcome Chemical Research Laboratories, describes some recent developments in the use of chaulmoogra oil in the treatment of leprosy. It appears that Dr. J. McDonald and Professor Dean, working in Hawaii, have obtained promising results by the treatment of this disease with the ethyl esters of the fatty acids peculiar to chaulmoogra oil. These acids were thoroughly investigated by Dr. F. B. Power and his collaborators some years ago and shown to differ from ordinary fatty acids in constitution and in being optically active.

Sir L. Rogers and others working in India have improved on the old method of administering chaulmoogra oil itself by using the sodium salts of fractions of the fatty acids for injection and also for oral administration, and the method in use in Hawaii appears to be a further development of this, by the use of fractionated ethyl esters in place of the sodium salts. Mechanically, at all events, the esters are better than the salts for injection. Rogers and his collaborators have recently found that they can get equally good results with the sodium salts of fatty acids from other oils than chaulmoogra, *e.g.*, gynocardia oil, and it therefore becomes a question whether the efficacy of certain oils as remedies for leprosy, and possibly also for tuberculosis, is not common to many oils and due, as has already been suggested, to their solvent power on the waxy external coating of acid-fast bacilli. Against this view is the evidence brought forward by Walker and Sweeney in California that the action of the chaulmoogra-oil fatty acids is specific against the leprosy bacillus *in vitro*.

Agricultural Industries in Jamaica.—According to a recent report of the Department of Agriculture, Jamaica, the period June, 1919, to June, 1920, marked the greatest industrial revival which the island has experienced during the past century. The recorded exports for 1919 increased by over 100 per cent. in value over those of the previous year, and there appears to be every prospect of stable markets for all the chief products of the various industries. Although Jamaica now produces many goods that were formerly imported, much still remains to be done, and it has been suggested that the following industries, *inter alia*, could be profitably initiated:—Condensed milk, cement, glass bottles, rope and string, and leather.

Marked progress was made in the sugar industry, exports being 38,000 tons, valued at £1,333,000, and £225,000 inclusive of rum. This record is expected to be much exceeded in 1920. The banana industry made a welcome recovery in the absence of hurricanes, and there were exported 10 million bunches of bananas and 20,000 boxes of evaporated bananas. The coconut crop showed a progressive recovery from the effects of the cyclone in 1917, with an export of over 24 million nuts and nearly 700 tons of copra. At no period of its history has Jamaica been so free from coconut diseases as at the present time, and the high value of the products is an incentive to increased cultivation. Logwood and its extracts have, contrary to expectation, enjoyed a revival of prosperity under post-war conditions, and an improvement of £60,000 over last year's values was recorded. Logwood is in strong demand at high prices, and all the local factories are working at full capacity. Orange oil realised good prices, and crop values are nearly double those of the previous year. Cacao had a good year, with an output value 90 per cent. greater than in 1919. Cotton cultivation has received some attention, and a small planting of Sea Island cotton resulted in a handsome profit to the grower. Pimento was in good demand abroad, the exports being valued at £184,000. Experiments on the production of pimento oil and its commercial conversion into vanillin are now being carried out at the Government Laboratory; if these are successful, Jamaica should command the world's markets for vanillin.

The production of sisal fibre is becoming an important new industry. The Government has already embarked on a large sisal enterprise at Lititz, where it has been shown that a minimum output of 1000 lb. of fibre per acre in the first cutting can be relied upon. This fibre has been thoroughly investigated in London, and offers have been received to buy all that can be produced at a very remunerative price. It is estimated that fibre to the value of £400,000 could be produced annually on land which has hitherto been comparatively unproductive. Hides were in good demand. When the tick question has been solved by the compulsory dipping regulations which will shortly come into force, a decided appreciation in the value of the hides produced in Jamacia should result.

Pimento-leaf Oil in Jamaica.—Investigations at the Government Laboratory of Jamaica have shown that the pimento leaf yields about 1·8 per cent. of eugenol, from which iso-eugenol and vanillin can be obtained. Iso-eugenol can also be obtained by the appropriate fermentation of pimento leaves. Eugenol could be used in the manufacture of vanillin and, as it is a strong antiseptic, it would be a suitable constituent of dental and toilet preparations. Jamaica could produce 100,000 lb. of pimento-leaf oil per annum from waste materials were a market available.—(*U.S. Com. Rep., Nov.* 1, 1920.)

Borates (1913—1919). (*Imperial Mineral Resources Bureau. Pp.* 24. *Price* 9*d.*).—The natural borates of industrial value include, in the order of importance, (1) ulexite (hydrated borate of sodium and calcium), (2) colemanite (hydrated calcium borate), (3) boracite or Turkish pandermite (borate and chloride of magnesium), (4) sassolite (native boric acid occurring chiefly in solution), and (5) borax (hydrated sodium borate).

As is well known, borax is used for many purposes, *e.g.*, as a flux in brazing and brass manufacture, as a constituent of pottery glazes and enamels, and as a glaze for paper and linen. It is employed in the tanning, glue, glass, and soap industries, and the borates of manganese and lead are used as drying agents in the paint trade. The perborates of calcium and sodium find application as a source of pure hydrogen peroxide, and hence also in the production of some modern bleaching powders.

Boron in the form of a suboxide is used to remove oxygen from copper just before casting, the conductivity and density of the metal being thereby greatly improved. It is also used in the manufacture of strong aluminium bronzes, in hardening and strengthening aluminium castings, and in the manufacture of nickel castings. Experiments conducted in France during the war indicated that remarkably strong and tough steels can be produced with the aid of ferro-boron. Another use of boron is as a voltage regulator in incandescent lamps, arc lamps, and other devices on series circuits.

The United States is now the great producer of crude borates, the production during the last three years amounting to over 80,000 metric tons per year. No analysis of the crude material is given, so that it is impossible to gain any idea as to the relative importance of the producing countries in terms of refined borax. The deposits are situated

throughout the Great Basin region, and in particular in the counties of Inyo, Kern, and San Bernardino in California and in the adjacent part of south-west Nevada. The borates are found in marshes and dried-up lakes, and are of a secondary character, being derived from beds of colemanite in the Tertiary lake sediments of the surrounding hills. Chile, Peru, and Bolivia rank next in order of importance as producers of borates. The western range of the Andes of South America contains many lofty volcanoes recently extinct, and around the base of these mountains there exist borax lakes sufficiently numerous to supply the world for many centuries to come, although but few of them have yet been developed. All of these deposits are owned and worked by a British company, Borax Consolidated, Ltd. No part of the British Empire produces borates at the present time. Our imports of calcium borate, borax, and boracite during 1919 amounted to 325,826 cwt., valued at £387,169, of which 13,416 cwt., worth £25,845, was exported.

The report contains detailed statistics concerning the foreign trade in borax and boric acid of the various portions of the British Empire, and interesting notes on the character of the world's deposits. It is to be regretted, however, that no statistics are given showing the production of refined borax in the chief producing countries.

The Petroleum Industry of Mexico.—Although the United States contributes about two-thirds of the oil supply of the world, 40 per cent. of the producing fields have become exhausted, and it is estimated that the oil reserves will be depleted within the next twenty-five years. The United States is at present an importer of oil, and this condition is bound to continue and to become more and more apparent. Mexico, ranking second as an oil producer, offers scope and encouragement not only to the American oil interests, but also to the Eastern hemisphere. Mexican production has increased threefold in the last seven years, as the following table shows:—

Year.	*Mexico.*	*U.S.*	*World.*
1913	25,902,439	248,446,230	384,667,550
1914	21,188,427	265,762,535	399,667,168
1915	32,910,508	281,104,104	426,370,894
1916	39,817,402	300,767,158	459,433,319
1917	55,292,770	335,315,303	505,362,367
1918	63,828,327	355,927,716	514,729,354
1919	87,359,533	377,719,000	

(The production is given in barrels of 42 galls. capacity)

Potential and Actual Production.—The potential production, *i.e.*, the amount that could be produced were each well allowed to flow without restraint, of Mexico during 1918 was 547 million barrels. Only about 12 per cent. of the potential capacity of the wells is being actually produced at the moment. This is partly due to lack of transport both for oil and materials, partly to lack of storage facilities, and partly to the political situation; moreover, new legislation has tended to check development.

Comparison of Mexican and American Wells.—The oldest wells in America are in the Appalachian field, and number about 100,000. The average production is ⅜ barrel per well per day; in the Californian field the average is 30 brls. daily per well, whilst there are 25 wells in Mexico which could produce freely 24,000 brls. per day per well.

New Mexican Fields.—The zone of potential production in the Gulf Coast States is estimated at 80 million acres, in the Pacific Coast at 50 million, and in Lower California at 18 million acres, a total, in all, of 230,000 square miles—of which only 6¼ million acres have been investigated. The actual producing fields cover 800 sq. miles. Geologists predict that a paraffin base oil may be looked for, or, at any rate, an oil of lower asphalt content than that produced at present.

The Salt Water Menace.—The Terpetate, Huasteca and Casiano fields have been seriously invaded by salt water. In November, 1919, the Casiano 7, producing 25,000 barrels per day, turned to salt water. This phenomenon will probably stimulate the exploration of the southern fields.

Pipe Lines and Transport.—Production is greatly restricted by insufficient transport. Pipe lines of total carrying capacity of 300,000 barrels per day are under construction and projected. Some of the very heavy and viscous oils cannot be moved in lines, tank cars are necessary, and even then heating facilities must be provided. The Tampico Panuco railroad is the most important common carrier in the oil region.

Storage and Refineries.—A great surplus of crude petroleum is stored in earthen reservoirs, awaiting improvement in transport facilities. In January, 1919, the tankage was 49 million brls., mainly steel, but to a limited extent concrete. There is a great need for refineries, and the Mexican Government proposes to encourage their establishment by the grant of concessions and franchise. There are four plants at Tampico, one each in Tuxpam, Vera Cruz and Minatitlam, with a total capacity of 100,000 brls. per day. About 20 per cent. of the oil exported is refined. New refineries are being contemplated and erected at Panuco, Tecomate, Tampico, and Mexico City.

Statistics for 1920.—For the first six months of the current year the oil exports from Mexico reached 60 million brls., a 72 per cent. increase over the corresponding period of 1919; the United States took 71 per cent. of the total production, South America 8 per cent. and Great Britain 4 per cent. The consumption of oil in Mexico itself amounted to 4 per cent. of the production.—(*Report of the Bureau of Foreign and Domestic Commerce, U.S.A.*

Sesame Seed in Mexico.—The production of sesame seed in Mexico is capable of great expansion, as the climate of the chief producing states, Michoacan, Guerrero, Marelos, and Vera Cruz, is admirably suited to the crop, and large areas of untilled land are available. The white and brown varieties of sesame grown in the country have an oil content officially estimated at 50 per cent., but although the former is stated to be richer in oil the latter grows more rapidly and produces more crops in a given period of time. The methods employed for separating the oil are said to be more modern than those used for olive oil in Spain and Italy. The first-grade oil is almost odourless and is used as a substitute for olive oil as well as in the manufacture of oleomargarine and in the adulteration of other edible oils. The inferior grades, which are usually rancid, are used for soapmaking, as a combustible, and as a basis for perfumes. The cake remaining after extraction is similar to cottonseed cake in value and is used as a cattle food. The leaves of the plant have medicinal properties.—(*U.S. Com. Rep., Oct.* 30, 1920.)

The Asbestos Industry in Russia.—The Russian asbestos industry suffered greatly during the war, and the production fell from about 24,500 long tons in 1913 to 4000 t. in 1919. The industry is situated in the Urals, and prior to the war 70 per cent. of the production was taken by Great Britain, Germany and Austria. Great difficulty is being encountered in the work, especially with labour, owing chiefly to the seasonal character of the operations. The labour costs for 1920 are estimated at over 52 million roubles, a much higher sum than in previous years and more than double the total capital invested in the industry.—(*Gummi-Zeitung, Oct.* 29, 1920.)

The Belgian Iron and Steel Industry.—The present position of the Belgian iron and steel industry, as compared with that in 1913, is shown by the following statistics:—On October 1, 1913, 50 out of 58 blast furnaces were alight and the daily production of all pig iron was 7272 tons; on the same date in 1920, 21 out of 51 blast furnaces were alight, 30 being under reconstruction or not in use, and the daily production of pig iron was 3354 tons. Since July 1, 1920, the average daily production of pig iron for steel manufacture has increased by 22 per cent., that of pig iron for castings has increased by 100 per cent., and four more blast furnaces have been blown in.—(*Bd. of Trade J.*, Dec. 2, 1920.)

Lectures on Glass.—The British Lampblown Scientific Glassware Manufacturers' Association has arranged a series of lectures in connexion with the Lampblown Glass Industry, to be held at the Northampton Polytechnic Institute, Clerkenwell, E.C. 1, on Wednesdays at 7.30 p.m. from January 5 to March 23, inclusive. Prof. W. E. S. Turner will lecture on Glass Tubing (Jan. 26); Mr. English on Glass Manipulation at the Bench (Jan. 19), Mechanical Devices (Feb. 2), Graduation of Apparatus (Feb. 9); Mr. Higgins on Thermometry and Thermometers (Feb. 16, 23, Mar. 2); Mr. Stott on Volumetric Glassware (Mar. 9, 16), and Mr. Davis on Chemical Glassware (Mar. 23). The fee for non-members of the Association is 10s. 6d. for the course, or 2s. 6d. per lecture. Further information may be obtained from the Secretary of the Association, Mr. H. W. Ashfield, at 2/3, Duke Street, St. James, S.W. 1.

PERSONALIA.

The honour of knighthood has been conferred upon Prof. James Walker, professor of chemistry in the University of Edinburgh.

Dr. Harriette Chick has been awarded the Mickle Fellowship of the University of London for her work on diseases due to defective nutrition.

Mr. A. W. Ambrose has succeeded Mr. J. O. Lewis as chief petroleum technologist to the United States Bureau of Mines.

Dr. C. J. Witt, assistant professor of analytical chemistry in the University of Pittsburgh, has become chief research chemist to the Portland Cement Association, U.S.A.

Dr. C. O. Johns, head of the colour laboratory of the Bureau of Chemistry, U.S. Department of Agriculture, has been appointed director of a new department of general research of the Standard Oil Company, New Jersey.

Dr. W. H. Walker has resigned from the directorship of the Division of Industrial Co-operation and Research of the Massachusetts Institute of Technology, and Mr. C. L. Norton, professor of industrial physics at the Institute, has been appointed in his stead.

Prof. Fr. Dolezalek, founder and director of the Physical and Electrochemical Institute in the Technical "Hochschule" of Berlin, died on December 10, aged forty-eight.

We regret to announce the death on December 1 last of Mr. Robert Tervet, of Leyton, Essex, an original member of this Society, who contributed papers on destructive distillation and on the production of ammonia from coke, showing the possibility of obtaining a yield of ammonia equivalent to 57 lb. of sulphate of ammonia per ton of coal by passing hydrogen over the incandescent coke remaining after carbonisation, the hydrogen combining with the residual nitrogen of the coke.

PARLIAMENTARY NEWS.

HOUSE OF LORDS.

In the House of Lords on December 23, Lord Cawley gave notice of his intention to move next session for a Committee of Inquiry into the circumstances attending the formation of British Dyestuffs Corporation, Ltd., and into its connexion with the Government.

HOUSE OF COMMONS.

Exports of Cement.

Replying to Lieut.-Col. Croft, Sir R. Horne said that there was now a shortage of cement in this country, but the output was improving. The exports for the first eleven months of 1920 represented about 23 per cent. of the output, which was, roughly, the pre-war proportion, and consisted of 246,184 tons (£1,338,000) sent to foreign countries and 318,939 t. (£2,022,000) sent to British Possessions.—(Dec. 20.)

Substitutes for Salvarsan and Neo-Salvarsan.

In answer to Mr. Waterson, Dr. Addison said that the following substitutes for salvarsan and neo-salvarsan had been approved:—Kharsivan, neo-kharsivan, arsenobillon, novarsenobillon, diarsenol, neo-diarsenol, galyl, and salvarsan (manufactured by an English firm). These drugs were all officially tested for toxicity before being placed on sale, and there was good reason to believe that, with the exception of galyl, they all corresponded in general chemical constitution to the analogous German preparations.—(Dec. 20.)

Metalliferous Mines (Legislation).

Mr. Bridgeman, answering Mr. Cape, said that a Metalliferous Mines Bill was being prepared, but it was improbable that it could be introduced next session.—(Dec. 21).

Coal Output.

In a written answer to Mr. Purchase, Mr. Bridgeman stated that the coal output during the week ended November 20 (the first full week since the coal strike) and during the three following weeks was 5,210,700, 5,176,500, 5,176,200, and 5,205,400 tons respectively. Weekly figures for the corresponding pre-war period were not available. Until the figures for the last week of the test period were obtained it was impossible to state how the wages scale would be affected. The present position of the industry did not warrant any hopes of cheaper home coal.—(Dec. 21).

Wet Carbonising, Ltd.

Mr. Bonar Law, in a written answer to Mr. Bottomley, stated that Wet Carbonising, Ltd., guaranteed a contract by its subsidiary, Lochar Ltd., for the purchase of the Ironhurst Peat Fuel Factory, near Dumfries, from the Government for £370,000. These companies had been unable to raise the necessary capital, and Wet Carbonising, Ltd., would be responsible to the Government for any deficit that might ensue if the factory were sold elsewhere for less than the guaranteed price.—(Dec. 22.)

The Royal Assent has been signified to the British Empire Exhibition (Guarantee) Act, 1920, to the Women and Young Persons (Employment in Lead Processes) Act, 1920, and to the Employment of Women, Young Persons and Children Act, 1920. The Electricity (Supply) (No. 2) Bill was withdrawn on December 20.

Parliament has been prorogued to February 15, 1921.

GOVERNMENT ORDERS AND NOTICES.

Import and Export Restrictions, etc.—The importation of hops is prohibited, save under licence or for transhipment, as from December 28, 1920.

All licences for the export of whisky granted prior to January 1, 1921, will be revoked as from February 1 next.

The following articles have been removed from Lists A and B of prohibited exports, as from December 30, 1920:—Potash, muriate and sulphate, crude manurial potash salts, and mixtures containing any of these substances; potassium permanganate; sugar, beet and cane.

The Commissioners of Custom and Excise have issued alterations in the Import and Export List, and the revised List will be published shortly. The *Board of Trade Journal* for January 6 contains a revised list of the foreign countries and British Possessions for use in the Monthly and Annual Trade Returns.

Importation of Dyes under the Dyestuffs (Import Regulation) Act, 1920.—The Board of Trade announces that applications for import licences required for any goods covered by the Act should be addressed to the Secretary, Dyestuffs Advisory Licensing Committee, Danlee Buildings, 53, Spring Gardens, Manchester. Applicants must supply full information concerning the wares they wish to import.

Appointments under the Gas Regulation Act, 1920.—The Board of Trade has appointed Sir R. T. Glazebrook to be Chief Gas Examiner, and Messrs. O. V. Boys, J. S. Haldane, and W. J. A. Butterfield to be Gas Referees. Mr. H. C. Honey is appointed Director of Gas Administration in the Power Transport and Economic Department, Board of Trade Offices, Great George Street, S.W. 1. A committee consisting of Sir W. Pearce (chairman), Dr. T. Carnwath, Mr. W. D. Gibb, and Dr. T. Gray, has been set up to inquire into the necessity or desirability of prescribing a limit to the carbon-monoxide content of gas used for domestic purposes; and also a committee, consisting of Mr. J. H. Gray (chairman), Mr. W. J. Butterfield, and Dr. C. H. Lander, with similar terms of reference, but relating to incombustible constituents.

Proposed New Regulations for Chemical Works.—The Home Secretary has issued a draft of the new regulations he proposes to make to supersede those made in 1908 for the manufacture of nitro and amido derivatives of benzene and those made in 1913 for the manufacture of chromate and bichromate of sodium and potassium. The new regulations are divided into those which are applicable to all chemical works, as defined in the schedule, and those relating to works in which there are special dangers. The manufactures of certain lead compounds, already dealt with in special codes, are excluded, and also processes of bleaching, dyeing, mercerising, tanning, brewing, alcohol distillation, and all experimental processes. Copies of the draft regulations may be obtained from the Factory Department, Home Office, S.W. 1, and objections must be lodged within 30 days of December 24.

Orders Cancelled.—The Oil and Fat Compound (Licensing of Manufacturers and Requisition) Order, 1918, the Seeds, Oils and Fats Order, 1919, and the Cattle Cakes and Meals (Licensing) Order, 1919, have been revoked, as from December 23.

Increased Wages in the Chemical Industry.—The Industrial Court has awarded to plain time-workers increases in wages which amount to, in general, 39s. 6d. a week plus 12½ per cent. on total earnings over the pre-war rates, and equivalent advances to pieceworkers.

OFFICIAL TRADE INTELLIGENCE.

(From the Board of Trade Journal for December 23 and 30, and January 6.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number:—

Locality of Firm or Agent.	Materials.	Reference Number.
Australia	Chemicals, oils, grease	891
"	Crockery, glassware	3
Canada	Copper and brass rods, tubes and sheets, tinplate	858
"	Tiles, fire-brick, glass, marble, slate	*
"	Soda ash	†
Hong Kong ..	Chemicals	865
New Zealand ..	Chemicals, dyes, paper	7
South Africa ..	Solid-drawn hard copper tubing..	860
" ..	Antifriction grease, paint, glass, wrapping paper	861
Belgium	Glue, glass-paper, varnish ..	869
"	Bichromate and permanganate of potash, sodium bicarbonate, paraffin wax, petroleum jelly ..	870
"	Chemical and pharmaceutical products, materials for the manufacture of chocolate and perfumery..	11
Bulgaria	Articles in demand include oils, grease, emery, iron, cement, mineral oils, copper sulphate, paper, window glass, dyes, colours, chemicals, lead, copper, tinplate, and wire	
France	Chemicals, cattle foods, fertilisers	875
Greece	Glass and china ware, leather, dyes, and photographic goods..	13a
Italy	Chemical and pharmaceutical products	879
"	Tinplate, steel and iron tubes ..	14
Latvia	Copper tubing	15
Switzerland & Italy	Heavy and pharmaceutical chemicals, oils, fats	883
Morocco	China and glass ware	22a
China	Scientific supplies	898
Japan	Magnesium, aluminium, lead, tin, tinplate, steel sheets, caustic soda, soda ash, carbolic acid, fertilisers..	899
Brazil	Tinplate, tin, metals, chemical and pharmaceutical products, cement, paper	28
Chile	Glassware, pottery, explosives, paper	30
Mexico	Drugs, perfumes, leather (catalogues of)	887
Peru, Bolivia, Ecuador	Chocolate	888
United States ..	Antimony	885
" ..	Metals	25
" ..	Glassware	27

* The Canadian Government Trade Commissioner, 73, Basinghall Street, London, E.C. 2.

† The High Commissioner for Canada, 19, Victoria Street, London, S.W. 1.

Market Sought.—A firm in Japan wishes to get into touch with U.K. importers of camphor, menthol, vegetable and fish oils, starch, ground nuts, and isinglass. [899]

TARIFF. CUSTOMS. EXCISE.

Australia.—The embargo on the export of goods to Germany, Austria, Hungary, Turkey and Bulgaria has been removed.

Austria.—Customs duties when paid in bank notes have to be paid at 40 times the rates prescribed by the Tariff as from December 1.

Belgium.—Export licences are no longer required for steel ingots, etc., fire-bricks, chemical manures

(with certain exceptions), certain oil-seeds, bone and bone powder, newsprint paper, and natural phosphate.

British Guiana.—The prohibition of the import of dyes and dyestuffs not manufactured within the British Empire has been temporarily withdrawn.

British Honduras.—The new customs tariff came into force on October 12, 1920.

Among the articles exempted from duty are coco-nuts, cohune nuts, certain drugs, charcoal, raw rubber, balata, chicle, raw hides and skins, horns, bones, fertilisers, fungicides, insecticides, copra, quinine, sand, slate, scientific apparatus, certain tanning and dying materials, tonca beans, serums, and radium.

The articles admitted duty free under the British Preferential Tariff include explosives (except sporting), tiles, bricks, cement, barbed wire, un-skimmed condensed milk, fuel and lubricating oils, newsprint paper, and rock salt.

Canada.—Drawback of 99 per cent. of the duties paid is now allowed on the materials used in the manufacture of margarine.

The customs duty on condensed milk has been increased; and the "luxury" taxes, with certain exceptions, have been repealed.

Colombia.—The export of gold is now permitted.

Costa Rica.—The text of the revised consular regulations of Costa Rica may be seen at the Department, 18, Queen Anne's Gate, S.W. 1.

Denmark.—Export prohibitions have been removed from, *inter alia*, cement, gypsum, prepared hides and skins, leather, old cast iron, fertilisers (except potash compounds), starch, soda, and tar.

Egypt.—The issue for January 6 contains a list of the revised tariff valuations for use in assessing the duties on imported non-ferrous metals.

Germany.—The detailed list of "controlled" imports may be seen at the Department, 18, Queen Anne's Gate, S.W. 1.

The import of waste paper, paper clippings, and paper, pasteboard and pasteboard wares suitable only for re-pulping is allowed without licence.

Among the articles for which no import licence is required are raw cocoa, rubber, gutta-percha, balata, certain feeding stuffs, asbestos, and some glass wares.

No export licence is required for ambergris, night tapers of waxed thread, natural spring salts, raw silk, wax cloth, emery cloth, carbons for arc lamps, certain wares of talc, asphalt and glass, spun silver and aluminium, and threads of common metals.

Italy.—The surcharge on customs duties when paid in paper money is fixed at 200 per cent. as from December 15, 1920.

Export licences are no longer required for, *inter alia*, bichromates of soda and potash, dinitrotoluol, milk sugar, certain medicines, tin, aluminium and zinc ash. Export licences are now required for linseed and maize cakes, pyrites, etc.

Lithuania.—The export duty on linseed has been increased from 25 to 30 marks per poud.

Luxemburg.—The export is now permitted of tin, pottery, earthenware, ceramic wares, india-rubber and india-rubber wares. An import licence is still required for cement, and the import of saccharin is prohibited.

Mexico.—Recent modifications of the customs tariff are set out in the issue for January 6.

The export duty on copper has been removed.

New Zealand (*Samoa*).—The customs tariff is set out in the issue for January 6.

Northern Rhodesia.—The customs and excise duties on spirits have been amended as from October 16, 1920.

The importation of certain dyes and dyestuffs not manufactured within the British Empire is prohibited.

St. Vincent.—The prohibition of the export of hides and skins has been revoked, and that on the import of certain dyes has been temporarily suspended.

Serb-Croat-Slovene State.—The period during which goods may remain in customs warehouses has been reduced to five days, and outside the warehouse to ten days, after which the goods will be sold.

Sweden.—Among the articles still subject to export licence are crude phosphate (except apatite), asbestos, asphalt, colours, lard, tallow, margarine, starch, cattle foods, milk powder, yeast, sugar, syrup, glucose, colouring matter, certain hides and leathers, vegetable fibres, certain metals and alloys, mineral oils, vegetable oils (with some exceptions), varnish, putty, caustic potash, potash salts, tin salts, indigo, Chilean nitrate, and animal waste.

Switzerland.—Special export licences are still required for, *inter alia*, cocoa, chocolate, sugar, preserved milk, oil cake, hides, skins, sole leather, charcoal, fibrous materials for the manufacture of paper, rubber, gutta-percha, porcelain insulators, certain kinds of glass, certain ores, metals and metal scraps, alkaloids, saccharin, certain chemicals, pitch, sulphur, turpentine, tar, caustic potash and soda, dyes, colours, colour varnish, and mineral oils.

Tripolitania and Cyrenaica.—The import duty on spirits has been increased.

Tunis.—A special tax of 2 fr. per metric ton is payable on exports of phosphates, in addition to the duty of 50 cts. per metric ton.

TRADE NOTES.

BRITISH.

Cyprus in 1919–20.—Cyprus is essentially an agricultural country, the chief products being fruit, cotton, sumac, and castor oil. Good results have been obtained in the cultivation of beetroot, but experimental plots of sugar-cane were a failure. Wine-making is, however, very prosperous. The forests constitute very valuable resources, and experiments on the distillation of forest produce for the production of pyroligneous acid have been continued. Difficulties in obtaining supplies have hindered mining operations, but these have been overcome and preparations for working on a large scale have begun. The Cyprus Mines Corporation has extracted 820 tons of cupriferous iron pyrites. A local syndicate, which acquired the property of the Cyprian Mining Co., was actively engaged in mining asbestos at Amiandos. Gypsum and umber were also produced.

The imports were valued at £1,525,427 (£1,013,582 in 1918), and were chiefly of British origin (81·2 per cent.). Exports amounting to £1,371,580 (510,235 increase) were directed mainly to British possessions (£664,424) and the United Kingdom (£313,455). The export of raw umber increased from 53 tons to 2785 tons, and the trade is rapidly increasing; the United States took 1254 t. of umber, Italy 986 t., and the United Kingdom 335 t.—(*Col. Rep.-Ann., No.* 1046, *Nov.*, 1920.)

FOREIGN.

Soda Prices in Germany.—The Soda Syndicate has reduced the prices of soda products by 5 to 10 per cent.—(*Chem. Ind., Dec.* 8, 1920.)

Japanese Trade in Caustic Potash.—The annual pre-war requirement of Japan in caustic potash was about 11,160 long tons, half of which was supplied by home producers, and the rest mainly by England and the United States. The cessation of all imports during the war led to a great development of the home industry, and at the present time the annual production is about 13,400 t., though 22,000 t. might be produced by effecting improve-

ments in manufacture. In consequence of speculative buying the home market is flooded with supplies, and manufacturers are asking for a protective duty; but it is unlikely that this would lead to improvement so long as the raw material used remains so poor.—(*Chem. Ind., Dec.* 8, 1920.)

Peruvian Exports of Cochineal.—Ayacucho and Huanuco are the chief cochineal-producing districts of Peru. The production, which before the war was bought by German houses, is now practically all being sold to the United States. The total export in 1917 was 22,193 kg., of which the United States took 5385 kg., and Great Britain 6672 kg.; in 1918 the former country took 33,165 kg. Cochineal is exported to the United States and to Europe through the port of Callao.—(*Rev. Prod. Chim., Nov.* 15, 1920.)

REPORT.

Report of the Lubricants and Lubrication Inquiry Committee. *Department of Scientific and Industrial Research Advisory Council. Pp.* 126. *London: H.M. Stationery Office.* 1920. *Price 2s. 6d.*

Before the war the annual expenditure on lubricants in this country was six million pounds, and it was estimated that a saving of one to two million pounds could be effected if a systematic investigation on the subject was instituted and the results were made freely accessible to the public. The Advisory Council thereupon decided to set up a Lubricants Committee with the following reference:—"To prepare a memorandum on the field for research containing an analysis of the problems involved, together with a suggested scheme of research which would be likely to lead to valuable results." The committee was presided over by Mr. S. B. Donkin, and contained such well-known authorities as Archbutt, Boys, Deeley, Donnan, Sir C. Parsons, and Lord Rayleigh. A special sub-committee has compiled an exhaustive bibliography of the chemical, physical, and engineering aspects of lubrication which will be published shortly. A considerable amount of research is detailed in the report under notice, notably on the quality of "oiliness," which has been attributed to lubricating oils by so many workers. The National Physical Laboratory has, in particular, been active in the prosecution of these inquiries, which, however, have not yet been brought to a conclusion. Certain material and special aspects of lubrication were brought to the notice of the committee and have necessitated individual investigations and reports which in two cases (Cutting Lubricants and Solid Lubricants) have been issued to the public.

Of the research work carried out at Teddington may be mentioned (*a*) Tests with the Lanchester worm gear, including a variety of mineral, animal, and vegetable oils with and without the addition of graphite and "oildag"; (*b*) the effect of pressure on viscosity; (*c*) determination of the physical constants of oily and non-oily liquids; (*d*) special methods for the determination of viscosity of oils under pressure in bearings (Boys and Parsons); (*e*) Deeley's oil-testing apparatus; and (*f*) the cup and ball viscosimeter. A series of recommendations for future research is tabulated from chemical, physical, and engineering points of view.

Among the appendices may be noted Faust's paper on viscosity at high pressure, a series of researches by Hyde on the Lanchester gear with a variety of lubricants, papers by Parsons and Boys, Deeley and Thomson on viscosity determination, and notes on "oildag."

REVIEWS.

THE ART OF TECHNICAL WRITING.

Technical Writing. *By* T. A. Rickard. *Pp. iv.*+178. *(New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.* 1920.) *Price 8s. net.*

The number of books on English composition is legion; among the latest and best is the "Art of Writing," by Sir Arthur Quiller-Couch. But there is still room for a book on the art of writing the literature of science, and particularly the art of putting together communications intended for the pages of scientific and technical journals. It may be alleged that this is literature of no very high order. Elia would possibly have classed books on technology as among books that were no books. But Lamb lived in an unscientific age. Other times, other views. We live in an age of science, and science needs the proper expression of its message as much as any other branch of intellectual activity. "Science and literature," said Huxley, "are not two things, but two sides of the same thing." But, of course, the literature we class as belles-lettres—the literature of rhetoric, poetry, fiction, philology—is characterised by other attributes than those which distinguish the literature of science. There should be no occasion for passion or the play of emotion in a purely scientific disquisition. Thoughts that breathe are to be welcomed, but words that burn are not, and purple patches are out of place. But the fundamental principles of the art of literary expression are common to every branch of literature, and that of science, whether pure or applied, needs them no less than any other.

Men of science, as a class, are not infrequently reproached by humanists for their apparent disregard in their written work of all literary form. "The man of science," said Sir James Barrie, "appears to be the only man who has something to say, just now—and the only man who does not know how to say it." The generalisation is, of course, too sweeping, but every editor of a scientific journal will be ready to admit that there is substantial ground for its partial truth. The author of the book before us, at least, has no doubt of the fact as regards the technologist, and especially the engineer, who, he finds, "does bungle language deplorably. He makes a fetish of efficiency, yet he shows no regard for the effective use of one of his most important tools—the pen; he believes devoutly in accuracy, yet he employs a weapon of precision as carelessly as a small boy handles a gun." But it is not only the engineer who is thus at fault. Technical students as a class are equally to blame. This, to judge from the authorities the author cites, is widely recognised in America. Its cause, in the opinion of the Senate of the University of California, whch appears to have gravely considered the matter, is mainly due "to the unedifying influence of myriad examples of poor English" in the local press. The newspapers the student reads tend to spoil his taste for good English. In addition, he is affected by "a certain public prejudice against correctness of expression," presumably fostered by the local press, which in later life, when he is in "daily contact with illiterate men, inclines him to careless speech and slovenly writing." "The uneducated are inclined to resent any speech more polished than their own."

It is not for us to criticise a finding thus deliberately reached. American journalism, no doubt, has much to answer for. As a rule, its literary quality is not high, although all editors would not concur with the Denver journalist, quoted by our author, who maintained that literary form is "a mere frill," and that the main business is "to get there"—no matter how clumsily.

Examples of solecisms in the American press are quoted that would disgrace a schoolboy. "Our grandfathers used to read the Bible daily; we read the daily newspaper." "The time given to the piffle of the press is lamentable."

But why behold we the mote that is in our brother's eye, but consider not the beam that is in our own eye? This book, although based upon lectures delivered to American students, and primarily addressed to an American public, contains truths which we on this side of the Atlantic may well lay to heart. Journalese is not confined to the United States. We, too, have newspapers which as regards their literary quality not only follow but even seek to better the example of the Denver editor. It may be that their influence on the character of technical writing is inconsiderable, but the daily reading of "piffle" blunts our appreciation of good English and insensibly lowers our standard of excellence. Style can only be absorbed subconsciously by continued contact with the best authors.

Mr. Rickard's criticism, like all useful criticism, is constructive. If he points out a fault he shows how it should be amended. He enunciates rules and illustrates their application. It is remarkable how much he manages to pack into his 178 small octavo pages. He recognises that instruction by precept is long; by example, short and effectual. Considerations of space preclude any detailed attempt to deal even with the general principles he inculcates, but it may be of use to give a short summary of his teaching. Much of it, at first sight, seems almost axiomatic and so obvious that it hardly needs to be stated. But so are the Ten Commandments, yet it is found desirable to repeat them at least once a week. Trite as are the rules of good writing, many of them are more constantly honoured in the breach than in the observance.

Mr. Rickard's golden rule is: *Remember the reader*. Our first aim should be to be understood. Technical writing is the precise expression of special knowledge. We are enjoined to be natural; it is the key-note of good writing, as of good manners. The skilful use of the pen, *pace* Dogberry, is not a gift of nature. To write naturally you must exercise the faculty of writing until it becomes flexible and strong. Good writing depends not so much upon a large vocabulary as upon the choice of words. The dominant fault of the incapable writer is the employment of too many words. Verbosity is a sign of carelessness or of lack of time for proper time. A conscientious author has been known to apologise for the length of his book, like Pliny for the length of his letter, because he had not time to make it shorter. Don't be tempted into the use of high-sounding terms that may serve to cover ignorance. "I have often observed," said Macaulay, "that a fine Greek compound is an excellent substitute for a reason." Greek terms, like razors, are not to be flourished recklessly. Do not use words of classical origin unless you know their meaning and have some knowledge of their etymology. Clearness of statement necessitates precision. The technical term is a word of precision, but let precision be proportioned to accuracy. Do not try to be precise in matters that do not admit of accuracy. The technical writer must be sincere; sincerity is the first essential of all good work. Suit the style to the purpose; fitness is the essence of good taste. Discard the trivial words that are constantly at your elbow; brush aside a host of vapid superlatives. "The superlative," said Metternich, "is the mark of fools." For example, the little word "very" can be deleted nine times out of ten: it is an impediment to terse and perspicuous writing. "Very" makes a strong adjective but a weak adverb; if you employ "very" infrequently, you will find it very useful on occasion. The secret of a vigorous style is the rejection of the superfluous word, but do not hesitate to repeat a word in order to make yourself clear. Perspicuity is the better part of elegance. A doubtful meaning is worse than a grammatical error. Good writing calls for care—persistent care; it calls for a literary conscience that refuses to be satisfied with unfinished work. As the Latin tag has it: *Sœpe stylum vertas.*

These aphorisms, culled from various sections of this book, and largely in the author's own words, will serve to show the character of his work. It deserves to be read, marked, and learned by all who write for the technical press. We may not always agree with his judgments. There are no final or absolute standards in the art of writing, and even the greatest masters of prose may sometimes, like Homer, be thought to nod. But Mr. Rickard has at least the courage of his convictions, and his sincerity and candour merit our appreciation.

T. E. Thorpe.

Handbook of Patent Law of all Countries. *By* W. A. Thompson. *Eighteenth edition. Pp. vi.+157. (London: Stevens and Sons, Ltd.* 1920.) *Price 6s. net.*

This is a new edition, considerably revised in view of the extensive modifications which the patent law of the world has undergone during the years of war, of a well-known book. It is intended for the assistance of the public, and of inventors in particular, and is compiled from that point of view. The summary given of patent law is terse and popular in form. In substance it covers the points most likely to present themselves to an intending patentee. It is written in a breezy and readable style. Although the title refers only to patent law, the subject matter combines the cognate subjects of Trade Marks, Designs and Copyright registration, these subordinate subjects, however, being dealt with less systematically than the main theme.

In writing on such a subject as English patent law, it is almost impossible to deal satisfactorily with the historical aspects of the subjects, themselves extremely well worth study, in a few words. Thus a sentence such as the following:—"As a rule it is undesirable to make a body corporate one of the applicants, as it is not quite certain whether in such case every member of the said body has not an independent right to use the invention"—is probably misleading. The practice of making limited companies parties to patent applications is a very common one, and the suggestion that every member of such a company has an independent right to use the invention would certainly be received with considerable astonishment by any modern court. There are, no doubt, old dicta, applied primarily to franchises differing in kind from those conferred by a patent grant, which might be quoted in this connexion, but there is no real doubt that they would be promptly swept aside. So again the remark that:—"In old times it was held unconstitutional for the King to grant a monopoly to a foreigner resident abroad"—is a proposition which stands much in need of verification if it is to convey any just impression of the course of development of English law. Here condensation is hardly compatible with the usefully clear statement of the point intended to be made. On the other hand, a very slight amendment would set right the sentence which runs thus:—"The word" (invention) "is derived primarily, as is well known, from the latin *in venire* to come *in*."

These, however, are small matters; they do not affect the value of Mr. Thompson's book, which exhibits in a very compendious form the outlines of patent law in Great Britain, the British colonies

and dependencies and all foreign countries that grant patents. Of special interest to its readers will be the accessory information, such as the dates of the various patent laws digested and the populations concerned, which are systematically given. We miss from this what was very useful information in the earlier editions of the book, that is to say, notes of the patent office fees in the various countries.

There is one point of very general interest in respect of which Mr. Thompson has made himself the mouthpiece of a curiously mistaken notion about the British Patent Office. On page 19, speaking of the renewal fees payable under British patents, he says:—"The Board of Trade has power to reduce these taxes, which are much too high and bring large profit to the Treasury." The fact is that the Patent Office, although at present safely paying its way, can hardly be regarded as a revenue producing department at all. The Comptroller General's report for the year 1919 shows a total income from all sources, including profit on the sales of specifications, etc., of £404,474, whilst the expenses of running the establishment were £350,150, showing a profit income of £54,324, which is no more than would be expected to be realised on a commercial venture of corresponding magnitude. No doubt there are risks attending ordinary commercial enterprises from which the business of conducting the Patent Office is free, and the 12 per cent. profit balance may be looked upon as a tax charged upon patentees; but it certainly is a very moderate tax and, having regard to the fact that no patentee pays it unless it is worth his while to do so, the complaint in these days of inevitably high taxation is a little unworthy.

J. W. Gordon.

The Volatile Oils. *By* E. Gildemeister *and* Fr. Hoffmann. *Second Edition by* E. Gildemeister. *Authorised translation by* Edward Kremers. *Second Volume. Pp. xx.*+686. (*London: Longmans, Green and Co.*, 1920.) *Price* 32*s. net.*

Gildemeister and Hoffmann's work on "Essential Oils" is so well known as to need no recommendation from reviewers. The present volume, however, comes into existence under very unfortunate circumstances. Written mainly in 1912 in German, it was published in Germany in 1913. It appears to have been translated between 1913 and 1916 by Dr. Kremers, printed in 1916, and published in 1920. The translator has allowed himself to translate Dr. Gildemeister's preface, dated "Miltitz, near Leipzig, June, 1913," as "Miltitz, near Leipzig, June, 1916," which we think should not have been done, as no attempt has been made either by author or translator to bring the work beyond the original date of 1913.

The present volume follows the plan of Volume I., the essential oils being enumerated in the order of Engler's "Syllabus der Pflanzen-familien," and the oils dealt with are those up to and including those of the *Zygophyllaceæ* and some of those of the *Rutaceæ*.

If this work were being reviewed in 1913, the reviewer's task would be an easy one, and nothing but praise and commendation could be accorded to it. Unfortunately it is 1920, and the book is so considerably out of date that we think it a pity that it should not have at least been brought up to the latest date possible by the translator. The reason for this serious shortcoming is obvious, but none the less, although every chemist interested in essential oils will welcome the book, the work done between 1913 and 1920 in this field is so great that the book loses very much of its utility.

To illustrate this, attention may be called to a few only of the more important omissions as types of those occurring throughout the volume.

Under the various cedar-wood oils no account is to be found of the work of Roberts on the oil of *Cedrus deodara* (1916), and the interesting researches of Schimmel and Co. on the ketone contained therein (1917). The latest work on cryptomeria oil dealt with is that of Kimura (*cf.* Berichte, 1909, p. 372); but in 1916 So Uchida discovered a crystalline diterpene in the oil, and published interesting details of the odorous alcohol present in the oil. The latest work on the chamæcyparis oils is dated 1910, so that Schorger's work (1914) and Uchida's (1916) are not mentioned. Still, keeping to the *Pinaceæ*, we find no references to Parry's work on "Russian Oil of Turpentine," which was published in 1912, nor, of course, to the exhaustive reports on the various turpentine and wood-turpentine oils of the different pines in the United States made by Schorger and Adams in 1915.

Turning to the oils of the *Gramineæ*, we are pleased to notice that at last we have a definite agreement that "the quality of citronella oil is best ascertained by the quantitative determination of the acetylisable constituents." Those who have perused Messrs. Schimmel's reports for the past ten years will remember how strenuously certain British analysts insisted upon this for years, and how vigorously Messrs. Schimmel and Co. opposed it. It is, however, regrettable that the acetylation is directed to be carried out with equal volumes of the oil and acetic anhydride. This will always give too low results, especially with oils of the Java type, and 10 c.c. of the oil should be treated with 15 c.c. of acetic anhydride. The data concerning ginger oil are, from the cause indicated above, quite out of date, as Brooks in 1916 identified in it the following substances:—methylheptenone, nonyl aldehyde, linalol, and zingiberol.

A few words only are devoted to the important oils of False Cubebs. This subject was exhaustively dealt with by Oranje in 1914, and any account must necessarily be quite incomplete without reference to this work. Equally true is it that Rabak's interesting work on "Oil of Hops" (1914) is unnoticed; the oil of *Cinnamomum Oliveri* is dealt with on the basis of Baker's work of 1897, which has been superseded and partially contradicted by that of Hargreaves in 1916; oil of massoy bark is stated to contain safrol, Messrs. Schimmel and Co. being the authority; whereas in 1917 the same authority stated that safrol could not be detected. The above are merely a few examples of the inevitable result of publishing in 1920 a work written in 1913 on a rapidly moving branch of chemistry. Due allowance having been made for this circumstance, and judging the book as in 1913, one may accurately describe it as being particularly free from errors of any kind.

THE CONDITION AND PROSPECTS OF THE BRITISH CERAMIC INDUSTRY.

J. A. AUDLEY.

Less than a year ago an Australian buyer entered the office of a well-known North Staffordshire earthenware manufactory, laid down a cheque for £10,000, and said in effect, "There you are! What can you do for us?" It can readily be understood that the manufacturers' representative keenly regretted the necessity of having to explain that it was impossible to do anything at all for at least twelve months. Within the last two or three years incidents of the same kind, though varying as regards the money value concerned, have been by no means infrequent in the ceramic industry. This state of affairs could not, in the nature of things, last indefinitely, and as regards some classes of ceramic products new conditions have already arisen.

It will be remembered that one outstanding consequence of the great war was an enormous dislocation of international trade and commerce. Many things formerly obtained mostly from abroad, and which were included in the category of necessaries, had to be provided somehow in ır own country. The manufacture of articles by ɔople with limited experience—workers and ıpervisors alike—and often under conditions of rgency requiring the promptest possible delivery : the goods, did not tend to the production of the ighest quality. The same was largely true also : ordinary commodities, because the ready sale at ɔmunerative prices for home consumption of ractically all classes of goods left no incentive › the manufacturers to seek improvements in ɔsign, shape, decoration, or general quality, unss such happened to be intimately associated with ıcreased output. Ceramic products were no exɔption to the general rule, and buyers have been ı an unusual degree at the mercy of the manuıcturers. The long period of delay in effecting world settlement has greatly helped to prevent ·ade from resuming or even approaching its ormal course, and the well-meant attempts to ɔtablish in this country a state of preparedness ɪr possible future wars—having regard to all the xisting circumstances it might not inaptly be xpressed as for probable future wars—has miliıted against any substantial reduction in prices. hese considerations, though general in their pplication, carry greater force in some directions ıan in others.

The china doll trade affords an instructive example. When few or no dolls were obtainable ·om abroad, home products supplied the market, ıt it is well understood that, with rare excepons, they were decidedly inferior to similar rticles formerly imported, besides being more exensive. Instead of seizing the opportunity to ɔtablish good models and to produce superior ware ·om them, the manufacturers were content to pile p profits on easily-made but inartistic goods. The ıevitable result is that when dolls from abroad re available, they are found to be not only ıeaper, but also much better than those made in ıis country. So too with fancy ware, which sold ell while there were no competitors and money as fairly plentiful, but failed lamentably when ıced with serious competition. This likewise was ue to the fact that no effort was made to adapt ıe ware to modern requirements as regards rtistic and other qualities, and the sale accordıgly fell away. There is still a demand for fancy oods, but not for inferior yet expensive ware which may be ranged in that class. As the world shortage of supplies gradually becomes satisfied, and as international trade relations with Russia, Germany, and other countries get restored, the vegetable and mineral exports from these places will have a powerful effect on the prices of similar commodities in America, and this in turn will affect the prices of pottery, etc., purchased in America from this country and elsewhere. It would therefore be wise for manufacturers to look forward and prepare for the coming fall in prices, to concentrate their efforts on lines that are likely to be in continued demand, avoiding particularly articles which will not be able to compete successfully with cheaper similar goods from other countries. This is not an absolute necessity in the economic situation at the moment, but the rapid changes and tendencies of that situation should be carefully studied, and suitable action taken from time to time in order to be prepared for developments. In this way the probable ill effects of the threatened fall in prices—or, at any rate, the worst of them—would be averted.

The supply of fuel has under present conditions been very far from satisfactory, especially as regards quality, and the restlessness among the coal miners has introduced an additional adverse factor, but the latter difficulty is now causing less anxiety, and improvements in other directions are also hoped for shortly.

The modern tendency to co-operation, which has already proved beneficial to the manufacturers in many industries, has within the last two or three years made such progress among pottery manufacturers that a British Pottery Manufacturers' Federation has been formed, and has already amply justified its existence, though serious difficulties still lie ahead. It includes most of the manufacturing firms, but not all. Before the war, wages in the pottery industry were notoriously low. The very abnormal conditions which resulted during and after the war provided a good opportunity for a great improvement to be made in this respect without causing any serious inconvenience. The poor pre-war wages scale was by some attributed to foreign competition, more especially on the part of Germany and Austria. This view was apparently negatived by the fact that by means of mass production of a few specialities, using modern appliances and methods, several British firms had actually competed successfully against German firms in Germany itself, in spite of tariffs and other obstacles. A much more probable explanation is that given by the representative of a prominent manufacturing firm, who candidly expressed his belief that it resulted from bad organisation.

There is less difficulty about a general rise in prices than in a fall. The inevitable fall in prices which will sooner or later follow a continuous decline in trade—the invariable sequence after the rise in prices which accompanies great wars, as far back as the wars of Napoleon at least, though the prices have never gone down to the pre-war level—will provide a troublesome problem for the industry, because the smaller manufacturers are much weaker economically than the larger firms, and any weakening on the part of the smaller firms will to some extent weaken the stronger position of the larger manufacturers. This difficulty might be met by the adoption on the part of the Manufacturers' Federation of appropriate schemes of selling; co-operative selling would be advantageous, especially for the smaller firms. This, however, can hardly be accomplished effectually unless standardised goods are produced under a system of scientific costing. Present prices were arrived at by merely adding percentages to pre-war prices,

but the latter differed from factory to factory according to the more or less economical production of the several articles, or to the varying amounts of the profits reserved by the different manufacturers.

British ceramic products, so far at least as the better class articles are concerned, are distinguished by the good potting of the body composition, and by the excellence of the glaze and colouring. So long as these features are maintained, the ware will always be in demand abroad, but the extent of that demand will depend largely on other considerations, notably on the selling price.

Chemical porcelain was entirely imported into Great Britain before the war; it was one of the few ceramic lines not produced in this country. When the supplies were no longer available, it became necessary to provide a substitute. A number of firms carried out experimental work, and most of them obtained encouraging results; of these firms the Royal Worcester Porcelain Co., Ltd., and Messrs. Doulton and Co., Ltd., persevered so far as to supply in quantity various articles for laboratory use, and continue to do so. Some of these British products were favourably reported on by the National Physical Laboratory. With reasonable care they may be used for most of the purposes of laboratory porcelain ware, but they can scarcely be regarded as more than serviceable substitutes, and it would not be correct to state that they are equal to the Berlin porcelain, for example, which stands very severe heating tests. The British ware has not the same composition, nor are the firing conditions the same as for the continental hard porcelain, and the continuance of a demand for it must presumably depend on the maintenance of a high quality, coupled with the ability to compete successfully as regards price with the foreign hard porcelain.

At the research establishment connected with the Stoke-on-Trent Pottery School, investigations have been carried on for about three years under the direction of Dr. J. W. Mellor and Mr. Bernard Moore, with a view to the production of hard porcelain. A type of hard porcelain suitable for domestic ware, and made from British materials by essentially British methods, constitutes one gratifying result of this work. Pieces have been produced exhibiting a wide range of colour decoration, and some manufacturers have undertaken to produce this ware on a commercial scale, but the prevalent abnormal trade conditions have for the time being hindered developments. True hard porcelain has also been made on a small scale at the same institution, but in this direction also no further development has yet taken place.

Brief mention may here be made of the "Vitreon" ware placed on the market by Messrs. Shanks and Co., Ltd. This is a fine white stoneware of great strength and impermeability, which is largely used for various articles needed in chemical manufacturing processes, and seems likely to compete successfully with the best German stoneware.

Royal Sanitary Institute.—The Henry Saxton Snell Prize of fifty guineas and the medal of the Institute are offered for an essay on "Suggestions for a System of Central Hot-Water Supply and Heating, adapted to Modern Housing Schemes, and to existing Groups of Houses." The essays, which should deal with the central installation, the distribution and conservation of the heat, the provision of continued supply during repair, the cost and combination with other services, must be sent before August 31, 1921, to the Secretary of the Institute, 90, Buckingham Palace Road, London, S.W., from whom all particulars can be obtained.

CHEMISTRY OF CLARIFICATION IN PLANTATION WHITE SUGAR MANUFACTURE.

J. P. OGILVIE.

In the Board of Trade returns relating to the importation of goods into the United Kingdom, all white sugars are collected for the sake of convenience under the heading of "refined." It is to be noted, however, that a good proportion of the white sugars bought by us since 1914 has been of the grade known as "plantation white," that is, a product made in the factory directly from the cane juice without being submitted to the refining process (which comprises re-solution, decolorising by passing through animal charcoal, and recrystallising). Such a tropical white sugar, though generally lacking the beautiful appearance of the best refined, has a ready sale, not only for use in the home, but largely in the confectionery, jam, biscuit, and condensed milk industries.

Undoubtedly, the clarification of the juice is the most important operation in making plantation white sugar. It is, therefore, of interest to notice briefly the essential differences between the procedure followed and that used in manufacturing the lower grade product requiring to be refined before it can be consumed.[1]

Cane juice as it comes from the mills is a light-grey to dark-green turbid and frothy fluid, which, in addition to sucrose and reducing sugars, contains in solution free organic acids (as aconitic, glycollic, oxalic, malic, etc.), organic and inorganic salts, gums and pectins, proteins, such colouring matters as anthocyanin, saccharetin, and the ferric-polyphenol compounds recently investigated by Zerban.[2] It also holds in suspension very fine particles of the crushed cane (so-called "cush-cush," or *bagacillo*), chlorophyll, wax, and lastly a little sand and clay, all of which solid impurities have escaped retention by the strainers of very fine mesh through which the liquid coming from the mills is preliminarily passed. Owing to its content in gums and pectins, it is unfortunately impracticable to filter the raw juice, either through cloth, sand, bagasse, or other medium.

In making ordinary raw sugar, the process of clarification adopted consists briefly in adding milk of lime to slight alkalinity or to neutrality (to litmus), heating to about 90° C., and allowing to subside in suitable settling tanks, the juice decanted from the scums and "mud" being sent to the multiple-effect evaporators for concentration to a syrup, from which the sugar is subsequently crystallised in the vacuum pan. This treatment is far from efficient in eliminating the soluble and insoluble impurities. It results in the free acids being neutralised, the proteins and nucleins being coagulated, and most of the floating "cush-cush," wax and clay being enveloped in the precipitate. Pectins and gums, it should be noted, are only partly eliminated by the small quantity of lime used. Regarding the colouring matters, the chlorophyll present in suspension is removed with the other floating substances, but the anthocyanin pigments coming from the bark of the cane remain to a large extent in the juice, adding very materially to its colour, especially if the variety of the cane being crushed is a very dark one. Saccharetin, which is a soluble pigment, and possesses the character of an indicator, being intensely yellow in alkaline solution, and colourless in an

---

[1] A very good account of tropical white sugar manufacture is given by Harloff and Schmidt in their "Handleiding voor Tropisch Witsuikerfabricatie," which has just reached its 4th edition. An English translation of this work (from the 2nd edition) appeared in 1913.

[2] This J., 1918, 778A; 1919, 192A.

acid medium, likewise remains, as do also the ferric-polyphenol compounds, which similarly contribute largely to the colour of the juice.

This method of treating with a small amount of lime, generally known as the "defecation process," by no means exerts the maximum clarifying effect. It gives a juice containing a certain amount of solid impurities in suspension, which accumulate in a rather dark syrup, and later during graining in the vacuum pan become incorporated between the *lamellæ* of the crystals, imparting to them a dirty colour incapable of removal by washing in the centrifugal machines with syrup, water, or steam. Not the least of the several defects of the defecation process, however, is that it may actually permit the formation of colouring matter. This is largely due (though apparently not entirely)[3] to the rather ready decomposition of dextrose and lævulose (comprising the so-called "glucose") at temperatures above 55° C., especially in an alkaline medium, viscous, dark-brown calcium salts of glucinic and saccharinic acids being produced. These decomposition products of "glucose" are probably the most inimical substances with which one has to deal in white sugar manufacture. They are only partly and temporarily bleached by sulphur dioxide, or by sodium hydrosulphite, and being very soluble persist through the several stages of manufacture, finally imparting a faint tinge of colour to the finished white sugar. Their formation must consequently be avoided as far as possible.

In white sugar manufacture, on the other hand, the method of clarification chosen is much more thorough, especially in regard to the elimination of the pectins and gums. Processes have been adopted which produce such a clarifying effect that these troublesome constituents are eliminated to a sufficient extent to enable the juice to be passed through cloth; which avoid largely the formation of decomposition products of "glucose" during evaporation; which permit crystallisation to take place in a syrup light in colour and free (or almost so) from insoluble matter; and lastly, which enable the molasses or mother-liquor adhering to the mass of crystals (the *massecuite*) dropped from the vacuum pan to be cleanly and easily removed by washing in the centrifugals. When these conditions are fulfilled, a sugar may be obtained of excellent colour, although as a rule one must admit that it is never so faultlessly white as the best crystals refined by the use of animal charcoal.

This improved clarifying effect is produced by the addition of an excess of lime, which is afterwards removed by means either of carbon dioxide (carbonatation), or of sulphur dioxide (sulphitation), a large amount of finely divided precipitate being thus formed in the juice. In this short note, it is impossible to present details of these processes and their several modifications, and space can only be found to describe the chemical effects resulting, so far as these are known.

In regard to the action of carbonatation and sulphitation on the constituents of the juice, it may be pointed out that proteins, nucleins, gums and pectins are partly removed from solution on the addition of the lime, and provided that sufficient of this reagent has been used all the anthocyanin is eliminated also. Altogether a considerably greater precipitation of impurities occurs than that resulting from the small amount of lime used in the defecation process. It is, however, the subsequent formation of the voluminous precipitate of calcium carbonate or calcium sulphite that completes the maximum clarifying effect obtainable; and there seems little doubt that adsorption of the colloidal impurities then occurs. That this is so appears to be supported by the fact that the order of addition of the alkali and acid may be reversed with no apparent difference in the result; as, for example, when the juice is first sulphited and afterwards limed (which, as a matter of fact, is the usual procedure in some countries).

[3] This J., 1920, 667A.

In a certain important modification of the carbonatation process that is now being used in factories in Java, instead of adding all the lime at once, liming and gassing are carried on almost simultaneously, conditions being so adjusted that only a slightly alkaline reaction is maintained throughout. This variation of de Haan[4] has proved very advantageous in practice for the reasons that the danger of colour formation by the action of an excess of lime on the "glucose" is avoided; that the utilisation of the gas is improved; that the operation is more rapid; that frothing (one of the inconveniences of ordinary carbonatation) does not occur; and, lastly, that less lime is required. But what is of interest to note is that it has been proved that this modification gives the same result in regard to the elimination of impurities as does ordinary carbonatation, in which a large excess of lime is allowed preliminarily to act upon the juice. Since during the de Haan treatment the amount of lime acting upon the impurities is probably little in excess of that used in the defecation process, it is difficult to believe that the elimination of the impurities effected is mainly due to its action. It seems much more reasonable to regard these observations as further evidence that the clarification of cane juice by such processes is largely an adsorption phenomenon rather than a purely chemical process.

In fact several workers, as Deerr, Norris, and Peck[5] have recently emphasised the importance of regarding clarification from the standpoint of colloid chemistry; whilst Geerligs in one of his latest works[6] points out that "the clarification of cane juice by chemicals does not eliminate from the juice any great amount of impurities but it is more the improvement of the physical properties which is effected, as, for example, the removal of the small amount of colloidal matter which hinders the juice from being filtered and keeps afloat the suspended ingredients. . . ."

Furthermore, Zerban,[7] in a publication which has just come to hand, shows by both laboratory and factory experiments that an efficient clarification can be brought about without the use of any chemicals at all; but simply by the use of efficient adsorbents. Kieselguhr and decolorising carbon were the materials used,[8] the procedure being to boil the juice coming from the mills with 0·5 per cent. of the infusorial earth, pass through cloth, heat with about 1 per cent. of high-power decolorising carbon, and again filter. Juice that was brilliant and almost colourless, and that gave an excellent quality and high yield of white sugar, was thus obtained.

This is certainly a result of much importance, which, it may be added, has been confirmed by tests carried out independently in certain factories in Louisiana. Its adoption in practice would depend mainly upon the availability of cheap and efficient adsorbents. There are on the market at the present time several decolorising carbons that are very satisfactory from the point of view of high adsorbing power; but the general opinion of sugar manufacturers and refiners appears to be that these are too costly for extended application. It would certainly be a matter of great interest to discover a means of producing at a low figure a carbon having a high power of adsorption towards the colloidal impurities, *e.g.*, the gums and pectins and colouring matters, present in sugar juices and syrups

whether this were obtained directly by a simple process of manufacture, or indirectly as a by-product.

Such a carbon, as these experiments of Zerban indicate, or some other cheap adsorbent, would doubtless find a wide application in the sugar industry. It would probably enable most tropical factories now turning out low-grade "raws" to produce white sugar which would surpass in quality that now obtainable by the carbonatation and sulphitation processes. It might ultimately be the means of realising the possibility, which some conceive, of producing directly from cane juice on the plantation a grade of sugar rivalling that now made only in the refinery.

THE ELECTRIC FURNACE IN THE AMERICAN METAL INDUSTRIES.

In the issue of *Chemical and Metallurgical Engineering* for November 17, 1920, appeared an article by R. M. Keeney on the technology and future possibilities of the electric furnace as applied to the manufacture of iron and steel, ferro-alloys, heat treatment, brass melting, and the smelting of non-ferrous ores. This paper, of which a short abstract is given below, forms a useful complement to the paper on recent developments of the electric furnace in Great Britain, which was read by D. F. Campbell at the annual meeting of this Society in July last (*cf.* J., 1920, 224 T).

During the last decade great progress has been made both in America and Canada in the application of electric furnaces to the iron and steel industries. Although this expansion was chiefly due to the exigencies of war, it is probable that the electric process will definitely supersede other processes for the production of steel castings and be widely used for the treatment of molten Bessemer and open-hearth steel.

Pig Iron.—The production of pig iron from electric smelting furnaces was for the first time proved a commercial proposition by D. A. Lyon at Heroult, California, in 1908. This process has been abandoned, and pig iron is now produced by electric melting of scrap. In Sweden and other countries, however, the development of the ore-smelting process has been steady, and both shaft and open-pit type furnaces have been used. The former resembles Lyon's shaft furnace, which was especially adapted for the production of low carbon and low-silicon iron, whereas with the latter, foundry iron can be produced and coke can be largely substituted for charcoal as a reducing agent. The future development of ore smelting in the United States is doubtful, but there is a possible future for the direct conversion of scrap iron and steel into pig-iron or castings. This synthetic process was largely developed in France, where 220,000 tons of iron was produced during 1916, 1917, and 1918. The electric furnace has also been used for desulphurising cupola metal and for the production of malleable castings.

Steel.—The number of furnaces in the United States and Canada has increased since 1907 from 7 to 363, whilst the output of electric steel in the United States for 1918 amounted to 511,364 gross tons. The electric process has found successful application in the manufacture of various alloy and high-speed steels, but when making carbon steel approaching best crucible quality only the purest raw material must be used.

Considerable development in the direction of refining molten metal may be looked for in the future, and already the Illinois Steel Co. has installed ten 30-ton furnaces for a triplex Bessemer open-hearth electric process.

Electric-steel Castings.—Electric-steel castings can now be made more cheaply than converter and open-hearth castings, even by firms purchasing their power from outside sources. The rapidity of melting ensures small but frequent supplies of liquid steel, which is very advantageous in foundries. As most foundries operate on a 10-hour day, a load factor of 18 to 30 per cent. only is possible, but where continuous operation is practised the load factor can be raised from 40 to 55 per cent.

Recent Modifications of Furnace Designs.—The design of recent types has generally followed the principle of the three-phase Heroult furnace. At the same time there has been a growing tendency towards the use of three-phase current and automatic control, the reduction of the reactance in primary circuits and the elimination of hearth conductors carrying all the current load. The best central station load is obtainable with furnaces operating at a power factor of 0·80 to 0·85.

Electrical Heat-treatment.—Considerable progress has been made with electric furnaces for the heat treatment of steel. The heating element consists of granular carbon confined in carborundum fire-sand troughs. The load is easily controlled by using a multi-tap furnace transformer. Single-phase furnaces of 900 k.w. capacity have already been installed, and this system of heating is certain to be greatly developed in spite of its higher cost. In another type of resistance furnace the heating element consists of a nickel-chromium alloy ribbon wound on a suitable framework; such furnaces have been built of 400 k.w. capacity.

Ferro-alloys.—In the last ten years the power capacity of ferro-alloy plants in the United States has increased from 20,000 to 200,000 k.v.a., but at the present time probably 75 per cent. of these plants is not operating. Further knowledge of the value of molybdenum as an addition to binary and ternary alloy steels has resulted in very marked increase in production of the ferro-alloy, whereas market conditions during the war were alone responsible for the increased output of ferro-manganese and ferro-chrome. These alloys are best made in three-phase furnaces, whilst the small single-phase furnace of Siemens type is preferred for smelting tungsten, molybdenum, uranium, and vanadium ores.

Brass.—The use of electric furnaces for melting non-ferrous metal and alloys has grown remarkably during the past five years. In March, 1920, there were 261 units installed with an estimated total load capacity of 23,000 k.v.a. One-third of this load is taken by resister furnaces, one half by arc furnaces, and the remainder by induction furnaces of small capacity. For brass-melting the power consumption varies from 250 to 400 k.w.-hrs. per ton. Single-phase furnaces are almost exclusively used.

Zinc.—Zinc is not being smelted commercially in the United States, although considerable experimental work has been done and the condenser problem apparently solved. In Sweden 15,000 k.v.a. is being utilised at two plants for ore and dross smelting.

Future Development.—The limitation of the electric furnace is primarily defined by the cost of power. For melting steel and non-ferrous metals a price of 1 cwt. per k.w. hour is reasonable, but this would prove altogether prohibitive for the production of ferro-alloys.

Future progress may be expected in the following processes:—(1) Iron castings from scrap or a duplex process of cupola melting with electric furnace refining; (2) steel castings and alloy steels; (3) ferro-alloys; (4) aluminium; (5) brass melting; and (6) electric smelting of non-ferrous ores.

SOCIETY OF CHEMICAL INDUSTRY.

JOINT MEETING OF THE SOCIETY WITH THE INSTITUTION OF MECHANICAL ENGINEERS.

A joint meeting of this Society and the Institution of Mechanical Engineers has been arranged, at which Monsieur Paul Kestner, President of the Société de Chimie Industrielle, will read a paper on "The De-gassing and Purification of Boiler Feed Water." All members of the Society will be cordially welcome to the meeting, which will be held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1, on Friday, March 4, at 6 p.m.

JANUARY MEETING OF COUNCIL.

The monthly meeting of the Council was held on January 14, Sir William J. Pope presiding. Among other matters dealt with the following may be mentioned:—

Arrangements were agreed upon for taking over the Society's share of the estate of the late Dr. Rudolph Messel, and it was resolved to comply with the testator's wish that the fund should be kept separate from the other funds of the Society. As, under the Society's by-laws, the trustees of the fund must not be members of Council, it was agreed to ask Dr. C. C. Carpenter, Mr. E. Grant Hooper, and Prof. G. G. Henderson to act in this capacity.

It was decided to proceed with the printing and publication of the fifth volume of the Society's Annual Reports of the Progress of Applied Chemistry, and that it should be sold to members at the price of 7s. 6d., and to non-members at 15s., plus 9d. postage, in each case. It was further resolved to offer to purchasers of Volume V. a set of the remaining copies of Volumes II., III., and IV. (Volume I. being out of print) at a reduction of 25 per cent. of the total price.

Seventy-nine new members were elected (as compared with 72 in January, 1920), of whom 64 are home members, 8 colonial, and 7 foreign.

The representatives appointed at the request of the National Physical Laboratory to consider its note on "Tests of Graduated Glassware" submitted a report on the subject, which was adopted by the Council, and ordered to be sent to the Director of the Laboratory.

On the nomination of the Committee of the Chemical Engineering Group, Messrs. C. S. Garland, C. L. Goodwin, J. W. Hinchley, W. R. Ormandy, and J. A. Reavell were elected the Society's representatives on the Chemical Engineering Committee of the British Engineering Standards Association.

The Council had before it a report received from the committee of the Nottingham Section on the subject of "The Recent Policy of the Publications Committee." The chairman and hon. secretary of the Section were present and amplified the views set forth in the report. A discussion followed, and the thanks of the meeting were given to the committee and its representatives for having brought forward the matter.

It was resolved that the Society as a whole should participate in the joint meeting to be held with the Institution of Mechanical Engineers on March 4 (*cf. s.*).

NEWS FROM THE SECTIONS.

MANCHESTER.

The fourth meeting of the session was held on January 7 at the Textile Institute, Mr. J. Allan presiding over an attendance of about eighty.

Dr. A. W. Crossley read a paper on "An Industrial Research Association," in which he discussed its objects, its relation to other research institutions, especially universities, and co-operative laboratories. Dr. Crossley contended that underlying theory was the fundamental object of research work and, applying this contention to the research laboratory established at Didsbury by the Cotton Research Association, said that it had been decided that the work there should not be based on previous industrial experience, but that investigation of the single fibre should be the fundamental object. Dr. Crossley also urged that the publication of all results is of the utmost importance. Among the points brought out in the discussion were the undesirability of reserving accommodation for research at universities to particular firms; that "investigation" was not necessarily "research"; and that much so-called rule-of-thumb work was essentially of a research character.

BRISTOL AND SOUTH WALES.

At the meeting held in Bristol on January 6, Mr. E. Walls presiding, Mr. C. E. Boucher read a paper on "Some Aspects of Chemical Work in Pharmacy."

Following a historical introduction, the lecturer discussed the difficulties connected with preparation, standardisation, and preservation, selecting opium as an example. He then outlined the trend of modern pharmacy, and laid particular stress upon the need for duty-free alcohol. The chairman also pressed the latter point, and spoke of the debt that the chemist owes to the pharmacist.

The first meeting of the Section in Swansea was held at the Royal Institution on January 7. Prof. C. M. Thompson, of Cardiff, presided, and members of the South Wales Section of the Institute of Chemistry were present by invitation.

In a paper on "Coal," Mr. C. A. Seyler outlined the development of its classification from the earlier attempts of Regnault, in 1837, to the more scientific methods now adopted, which are based on the relative amounts of carbon and hydrogen in the pure coal substance, and showed how well the results of these agreed with the data derived from the study of the geological and geographical distribution of the South Wales coalfield. He traced by means of charts and maps the gradual changes from the centres of anthracitisation outwards, showing how the physical, chemical, and palæobotanical characters change concurrently with the changes in carbon and hydrogen contents. The speaker showed slides of present and fossil forms of Lycopods and Sigillarias, compared these with a number of photomicrographs in natural colours, and pointed out the fossil structures therein.

The chairman announced that it was proposed to hold two meetings in Swansea next session, provided papers could be obtained from local members.

YORKSHIRE.

The second meeting of the session was held in Leeds on January 17, with Dr. L. L. Lloyd in the chair.

Mr. H. J. Hodsman described and exhibited a new form of apparatus for sodium peroxide fusions, which consists of an elongated steel crucible about 4 in. long by 1 in. in diameter and closed by a well-fitting lid. The crucible is encased in an outer steel tube the cover of which slips on with a bayonet joint. In this apparatus the fusion of organic substances, especially fuels, can be carried out safely and conveniently by simply heating the outer tube in a bunsen flame.

A short paper by Messrs. B. A. Burrell and G. W. Douglas, entitled "The Presence of Nitrates in the Leaves of Trees Growing near a Picric Acid Works," was read by the latter. Damaged and undamaged leaves were examined by extracting with cold water and estimating the nitrate content of

the extract by the colorimetric method, using brucine and oxalic acid. The damaged leaves all showed the presence of nitrate, the amount of which varied from 0·05 to 0·38 per cent. (expressed as nitric acid), whilst the undamaged leaves from the vicinity of the works and also from other districts of Yorkshire showed no trace. It was observed that beech trees were most susceptible to the fumes.

At the conclusion of the meeting a burette-holder, designed by Mr. F. Firth, was exhibited. The burette is held in a clip attached to a jointed arm similar to an ordinary gas bracket, so that it can be pulled forward when required and pushed back against the wall to leave the bench clear when not in use.

LIVERPOOL.

On December 17, Mr. P. G. Jackson read a paper on "Boiler Feed Water—from the chemist's point of view," in which he discussed the formation of scale in boilers, corrosion of the iron or steel of which they are constructed, of the brass or gun-metal fittings, overheating, and priming or foaming of the water. The various theories of corrosion, the author believes, are almost all correct, but the electrolytic theory is the only one which, in many cases, can explain why corrosion occurs at a particular point. Oxygen is difficult to remove, and usually must be allowed to remain, although in some cases a small quantity of tannic extract may be added; but as tannic acid is itself corrosive, it should be neutralised with soda, and then used only in small amount as the salt is readily dissociated. Undue aeration of a feed water should be carefully avoided. Corrosion due to oxygen and carbon dioxide may usually be recognised by the presence of gas bubbles on rough surfaces lying more or less horizontally, and where the water circulation is defective; in the latter case the pittings are nearly circular in shape, sharply-defined, and isolated. Much experience is necessary to infer from an analysis whether the magnesium salts present in a water are likely to cause corrosion. Magnesium chloride and nitrate, if present in more than very small quantities, are almost certain to cause it, unless sufficient calcium carbonate is present to neutralise their action. Nitrates, when in concentrated solution, cause trouble in boilers working at, say, 150 lb. per sq. in. pressure; the maximum permissible concentration should not exceed 100 grns. per gall. Iron and ammonium salts are especially deleterious, but, in the author's opinion, sodium carbonate is not corrosive.

After discussing the control of feed-water supplies with and without softening plant, Mr. Jackson described boiler troubles due to "priming," which he classified into "foaming" and "bumping." Foaming occurs readily when either soapy matter or certain colloidal organic substances are present in the water, and is probably due to the presence of large numbers of minute suspended particles acting as nuclei for the formation of steam bubbles and causing too rapid ebullition. Bumping may be prevented or minimised by providing ample steam space, excluding soapy water or saponifiable oils, avoiding excessive concentration of saline constituents, and by excluding finely-divided organic or mineral matter, and oil or other substances which may form a scum on the surface of the water. Overheating of certain parts of the boiler frequently occurs when the metal has become distorted or bulged, and is nearly always due to the presence of oil in the scale; and it is therefore very important to exclude grease from the boilers. Oil should be eliminated by chemical means; ordinary softening treatment will remove it from a hard water (with the precipitate), but for a soft water alumino-ferric should be used.

MEETINGS OF OTHER SOCIETIES.

THE CHEMICAL SOCIETY.

In a lecture delivered to the Chemical Society in December last, Sir Robert Robertson, Director of Explosives Research, Research Department, Woolwich, described some recent work carried out there on the "Properties of Explosives."

The lecture embodied an attempt to correlate the explosive properties of simple explosives with their chemical composition and constitution. It was shown that the percentage of oxygen which was required to oxidise the combustible elements in the explosive was intimately related to its properties, and also that constitutional changes, such as the arrangement of nitro-groups in isomeric compounds, were responsible for differences in the effects produced. The properties considered were heat of formation, heat of explosion and gases evolved, chemical stability, sensitiveness to shock, rate of detonation and pressure developed; and in each case the description was prefaced by an account of the most recent methods employed by the Research Department, Woolwich, for determining the values. In many cases quantitative results were obtained which make it possible to measure the properties of explosives in terms of definite physical units, instead of by personal estimates of effect, as hitherto.

The influence of the heat of formation as well as of the completeness of the oxygen balance was illustrated by a comparison of the thermal data given by nitroglycerin, trinitrotoluene and trinitrophenol, reference being made to a new set of values for heat of formation of the most important nitro-derivatives of benzene, toluene, phenol, and methylaniline. Values for the heat of explosion, obtained under conditions of standard density of loading of the explosive in its containing envelope, were quoted, and the similarity of trinitrotoluene and trinitrophenol in this respect was traced to the higher heat of formation caused by hydroxylation, as compared with methylation, of benzene.

The factors influencing rate of decomposition were discussed, and examples given of temperature coefficients. Variations in chemical stability were illustrated by a table in which the rate of gas-evolution from a number of explosives was compared at a common temperature, and the influence traced of such factors as the introduction of nitro-groups, of methyl groups, and of the hydroxyl group into the ring, the arrangement of the nitro-groups in the compound, and the physical condition of the explosive undergoing decomposition. The resistance to decomposition by heat was in many cases shown to run parallel with the ease with which the explosive compounds can be hydrolysed. Values for insensitiveness to shock were quoted for a number of explosives, and some effects noted of constitutional arrangements, such as want of symmetry in the disposition of nitro-groups, conducing to greater sensitiveness. The rates of detonation under conditions of high density of loading were given for a few explosives.

The important principle, enunciated by the late Prof. B. Hopkinson, concerning the measurement of the pressure of a blow was illustrated by a description of the work done on this quantitative method as applied to explosives. It consists essentially in the separation of the momentum of the blow into pressure and time, of which the latter is known. Attention was called to the necessity for maintaining constant the density of loading of the explosive and the thickness of its containing envelope. Values illustrating these points, as well as the effect of certain constitutional arrangements on the violence of the detonation were given, as were also indications of the applicability of the method to many problems in explosive research in

which the violence of the blow delivered has to be investigated.

In the second part of the lecture the explosive properties of the Amatols (mixtures of ammonium nitrate and trinitrotoluene) were described. These mixtures were put forward early in 1915 by the Research Department, Woolwich, to meet the shortage of trinitrotoluene, and ultimately were used in enormous quantities for filling shells, bombs, and other warlike appliances.

As Amatol 80:20 has its constituents nearly adjusted for complete combustion, its heat of detonation can be calculated, since the heats of formation of the constituents and final products are known. The values actually obtained for heat of explosion and for gases evolved in the high-explosive calorimetric bomb were shown to be in very fair agreement with the calculated quantities. The chemical stability of these mixtures and the influence on them of certain impurities were discussed, and the values obtained for sensitiveness and rate of detonation were given. The application of the pressure bar to the investigation of these mixtures clearly showed that the ammonium nitrate is not to be looked on as a diluent of the high explosive; it is more than a convenient source of oxygen, being itself an explosive.

The lecture, which contains many numerical values for which the original must be consulted (Chem. Soc. Trans., **119** (1921), p. 1), concluded with a tribute to the enthusiasm of the scientific staff of the Research Department, Woolwich.

At the meeting of the Society held on January 20, Sir J. J. Dobbie announced the deaths of Sir Lazarus Fletcher, head of the mineral department of the British Museum since 1878, of Mr. Charles Simmonds (*cf.* p. 29 R of this issue), and of Mr. S. A. Vasey, who directed the *Lancet* laboratory for twenty-eight years. The vacancies on the Council, to be filled at the annual meeting in March, were also announced.

The list of papers to be communicated contained twenty items, of which the following were read in abstract:—The formation of derivatives of tetrahydronaphthalene from γ-phenyl fatty acids: G. A. R. Kon and A. Stephenson. Quantitative reduction by hydriodic acid of halogenated malonyl derivatives. Pt. I.: The amides of sym. dialkyl and aryl substituted amides of mono- and di-bromomalonic acid: J. V. Backes, R. W. West, and M. A. Whiteley. Dihydroxynaphthaldehydes: G. T. Morgan and D. C. Vining. Researches on residual affinity and co-ordination. Pt. III.: Reactions of selenium and tellurium acetylacetones: G. T. Morgan and H. D. K. Drew. Ortho-chlorodinitrotoluenes. Pt. II.: G. T. Morgan. The constitution of catechin. Pt. III.: Synthesis of *acacatechin*: M. Nierenstein. Chlorine overvoltages: E. Newbery. The influence of mercury, sulphur, arsenic, and zinc on the catalytic activity of platinum: E. B. Maxted. The conditions underlying the formation of unsaturated and of cyclic compounds from halogenated open-chain derivatives. Pt. I.: Products derived from α-halogenated glutaric acids: C. K. Ingold.

There will be an informal meeting of the Society on February 3, following an ordinary scientific meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting held on January 11, arranged by the Scientific and Technical Group, the president announced that the Society's progress medal had been awarded to Mr. F. F. Renwick for researches in the chemistry and physics of photography.

Mr. J. Rheinberg, in discussing "Some New Directions for Photographic Research," dealt chiefly with the variation of the physical properties of colloids which can be induced by such factors as change of solvent, light action in presence of certain salts, etc. In his own work the most important property which he had controlled in this way was the permeability of colloidal membranes to certain solvents; for example, films of gum arabic or fish glue, sensitised with a ferric salt, became more permeable, on exposure to light, to slightly acidified alcohol, thus allowing the extraction of dye from an underlying collodion film. This property was utilised in the manufacture of a mosaic colour screen and also in preliminary experiments for the production of graticules, not carried to completion because of the discovery of the "grainless photography" method. He referred also to the advantage of using methyl alcohol as a solvent for pyroxylin, thus avoiding the objection to mixed ether and alcohol which by reason of their very different rates of evaporation lead to irregular films on drying.

In the paper on "White Light Development," Mr. B. V. Storr gave a short account of the work of Lüppo-Cramer on the reduction of light-sensitiveness of photographic emulsions produced by certain substances. The desensitising action possessed by developing solutions was found to vary considerably with different developers and to be greatest with amidol in the absence of sulphite; further experiments showed that the active desensitiser is the oxidation product of the developer, and this led to a search among dyes of similar composition to the oxidation products. The most active dyes discovered are those of the safranin class, a reduction of sensitiveness of as much as 600—700 times being obtained with phenosafranin. This property is the basis of the process of white light development, which was later demonstrated by Mr. Storr and Mr. H. Flower by developing Special Rapid and Panchromatic plates in white light, after a preliminary bathing in a 1/5000 dye solution. The dye used, of which samples were distributed amongst the members of the Society, was not phenosafranin, but a closely allied substance with some advantages in lesser staining and no tendency to produce veil. Messrs. Ilford, Ltd., hope to place this dye on the market very shortly, thus rendering the process available for general use in this country.

INSTITUTION OF PETROLEUM TECHNOLOGISTS.

At the meeting of the above Institution held on January 18, a paper on "The Carbonisation of Lubricating Oils in Internal Combustion Engines," by Mr. F. H. Garner, of the Mellon Institute, Pittsburgh, U.S.A., was read in the author's absence by Dr. W. R. Ormandy.

In this paper the author dealt with the cause of carbonisation of lubricating oils in the cylinders of high-speed internal combustion engines, and showed that the suction stroke of the engine is the most important of the whole cycle from the lubricating standpoint, the leakage of oil from the crank chamber during this stroke being the origin of the carbon deposits formed. The question of tests to determine the tendency of an oil to carbonise under such conditions was fully discussed, and a series of tests was given for carrying out these determinations. The carbonisation is influenced by the amount of asphaltic resins present in the oils. The method of determination of asphaltic resins given by the author was one based on that of Rakusin (J. Rus. Phy. Chim. Soc., 1916, 48, 720) in which the oil is mixed with animal charcoal. The asphaltic resins are adsorbed, and the free or loosely combined oil is then extracted by petroleum spirit, in which the adsorbed resins are insoluble; the latter are then estimated by extraction with

chloroform. Experimental work was carried out on a series of lubricating oils from Texas and Pennsylvania crude petroleum, and it was found that:—(a) Oils of similar distillation range have similar evaporation losses at the same temperature, irrespective of their origin; (b) there is a direct connexion between the evaporation loss and the fire test of an oil; (c) carbonisation, that is percentage of asphaltenes formed, increases on heating much more rapidly than the evaporation loss; (d) in similar oils the resin content influences the extent of carbonisation at high temperatures and also the coke value as determined by Conradson's method. The author stated that Conradson's method is a better criterion of the behaviour of the oil in the engine, as regards the formation of carbon deposits, than the carbonisation tests.

In the ensuing discussion, Mr. L. Archbutt stated that in carrying out carbonisation tests he used a large quantity of oil, heated it for 48 hrs., and then did comparative tests on viscosity and acidity; there was a direct relationship between the results of these tests and the behaviour of the oil in practice. Mr. E. A. Evans expressed the opinion that the question of carbonisation had hitherto been approached from a wrong standpoint, viz., that carbonisation was due to the decomposition of unsaturated hydrocarbons; this assumption was open to question. He was at present investigating the tendency of pure hydrocarbons to carbonise and was obtaining very interesting results. Mr. H. Barringer suggested that the carbonisation might be due to extraneous hydrocarbons present in the oil as now sold; and Mr. G. Pitt that oils should be sold on their carbonisation values. Dr. R. Lessing drew attention to the similarity of the asphaltic bodies to those present in coal tar. Dr. M. B. Blackler stated that he had had considerable experience during the past few years in the treatment of lubricating oils in order to obtain fully saturated medicinal oils, and suggested that the proportion of unsaturated hydrocarbons to saturated hydrocarbons in the oil played a great part in determining the carbonisation values.

Dr. W. R. Ormandy, in reply, mentioned that the Diesel Engine Users' Association had investigated the carbonisation of fuel oils in Diesel engines. In his opinion only coking tests gave reliable indications of the production of carbon in internal combustion engines. The so-called carbon in internal combustion engines was really not carbon, but a highly polymerised hydrocarbon or asphalt.

SOCIETY OF GLASS TECHNOLOGY.

The fortieth meeting of the Society of Glass Technology was held at the University, Sheffield, on January 19, Dr. M. W. Travers presiding.

The first paper, which was read by Prof. W. E. S. Turner, was by John Currie on "The Rate of Change of Glass Composition in a Tank Furnace following a Change in the Batch Composition." The tank furnace in question had a deadweight capacity of 106 tons, and was charged every 2 hours during six working days by the addition of 30 cwt. of batch and 4 cwt. of cullet. As it was desired to produce a bottle glass of lower melting point and slower rate of setting, the batch was altered so as to reduce the content of lime and alkali; and it was found that nearly three months elapsed before the composition of the glass produced was nearly identical with that calculated from the new batch.

The following two papers were then presented together by Prof. Turner:—(a) "Problems arising in Tank Furnace Practice through Shortage of Salt Cake": W. E. S. Turner; and (b) "The Relative Advantages and Disadvantages of Limestone, Burnt Lime, and Slaked Lime as Batch Materials": F. W. Hodkin and W. E. S. Turner. (a) Various substitutes for salt cake had been tried with success; in some cases one-half to two-thirds had been replaced by soda ash. Mr. Gelstharp, chemist to the Pittsburgh Plate Glass Co., had reported that a good clear glass, having more than a certain lime content, could not be made from a batch in which all the salt cake was replaced by soda ash. Among the advantages claimed for soda ash were:—(1) It was usually purer than salt cake; (2) a considerably greater proportion of its weight remained in the glass; (3) a soda-ash batch melts more readily than a salt-cake batch; (4) soda ash was usually transported more carefully by the railways; and (5) it had been stated that salt cake acted more corrosively on the refractory materials of the furnace. The relative prices of these two materials had, of course, to be considered. (b) The effects of limestone, burnt lime, and slaked lime had been tried in both salt-cake and soda-ash batches and in a batch containing a mixture of these. The form of the lime used had a considerable influence; but other factors were also operative. The higher cost of burnt lime was to some extent offset by the elimination of organic matter, which acted as a reducer in the tank and gave rise to glass of poor colour; *per contra*, it was difficult to handle, and it readily absorbed moisture and carbon dioxide. The use of limestone made the batch more expensive, but the gas it evolved helped to agitate the glass and thus produce greater homogeneity.

CORRESPONDENCE.

THE PROPOSED NEW REGULATIONS FOR CHEMICAL WORKS.

SIR,—The projected new regulations for chemical works issued by the Home Office (*cf.* J., 1920, 16 R) are, as a whole, reasonable and progressive. They are designed to protect the workman whilst following his employment from poisonous and other deleterious substances which advancing science has shown to be inimical to his health, and at the same time to compel employers to maintain such a reasonable standard of "welfare" work and good hygienic conditions of employment as the spirit of the times now regards as essential. Many of the details however, will require adjustment or slight rewording. The regulations regarding rescue appliance, working in offensive places, change of clothing, mess rooms and washing facilities, first-aid and ambulance room, drinking-water supply, are all to the good, and their provision will necessitate little or no expense to modern works, since they are already installed in most of them; and any provisions against poisoning by arseniuretted hydrogen are undoubtedly welcome.

The provision of bath accommodation (Regulation No. 15) has always been a disappointment to the progressive employer, as where installed, it has not been used to any extent by the worker. The provision for flooding and drenching with cold water persons splashed with dangerous corrosive liquids (No. 16. (a) 1.) is new, but would appear to be already covered by the provision of fire water-buckets throughout the works. Facilities for sitting down (No. 21) will, no doubt, meet with considerable opposition, as such provision can be so readily abused.

Regulation No. 29 prescribes that chlorate shall be crystallised, ground, and packed in a room or place set apart for the purpose, the floor of which must be smooth, made of impervious and incombustible material, such as cement, and be washed or sprinkled with water and swept daily. No. 31 (b) provides that all persons employed in such a room or space shall wear boots or overshoes

having no metal in them, and woollen clothing, which shall not be removed from the works for any purpose, and which shall be washed daily after use and thoroughly dried before being worn again. These regulations are very severe and go further than experience has demonstrated to be necessary. The washing or sprinkling with water of the floor is really an additional source of danger —daily sweeping is the greatest safeguard. Regulation No. 5, dealing with precautions to be taken against fires, should be amended so as to enable employers to summon workpeople before magistrates for infringing the regulations.—I am, Sir, etc.,

T. T. Best.

Manchester, January 11, 1921.

ORIGIN OF THE SOCIETY OF CHEMICAL INDUSTRY.

Sir,—As from time to time erroneous statements are made concerning the locality and the circumstances in which the Society of Chemical Industry was founded, and as a little knowledge of the Society's origin may prove interesting and useful, particularly to the younger generation of chemists, I have pleasure in sending you the following few recollections of those early days.

The Society of Chemical Industry, with its "nearly 6000 members" and the best Chemical Journal in the world, grew indirectly out of the Faraday Club, the members of which were chiefly works chemists in St. Helens. The Faraday Club held its meetings usually at Mrs. Boothby's, in Lime Street, Liverpool, occasionally in Widnes and Warrington, and later on in the North-Western Hotel, Liverpool. The Widnes men apparently grew somewhat jealous of the success of the Faraday Club, and determined to have a bigger society of their own. Mr. John Hargreaves (a younger brother of James Hargreaves of "saltcake" fame, and of the Hargreaves-Bird electrolytic soda process) accordingly sent out invitations to a meeting to be presided over by Mr. James Muspratt (a brother of E. K. Muspratt, the fifth President of the Society), at the Officers' Room, Drill Hall, Widnes. The Faraday Club members were invited to this meeting; they attended in force and managed to get the secretary (the late Mr. George E. Davis) and treasurer (myself) and another member appointed on the committee to draft the rules for the new society. Mr. G. E. Davis suggested that the Society should comprise the chemists of Widnes, St. Helens, Runcorn, Cheshire, and S.W. Lancashire. Somebody else—probably Mr. James Muspratt—proposed that the next meeting should be held in Manchester, and that Dr. (the late Sir Henry) Roscoe be invited to preside.

At the Manchester meeting a good deal of discussion took place about the name of the Society, many being in favour of making the engineering side more prominent. Mr. G. E. Davis proposed that the meetings be held alternately in London and the provinces, and I suggested that the Society should be co-extensive with the English-speaking world, with branches or "sections" in the chief chemical centres of England and America. This was carried, and the name finally adopted was "The Society of Chemical Industry." The first general meeting was held in London in 1881, in rooms kindly lent by the Institution of Civil Engineers, and was presided over by Dr. Roscoe.

If I were asked to name those who worked hardest to found the Society, I should certainly say Mr. G. E. Davis, who at the time of the formation of the Faraday Club, in 1875, was chemist at Messrs. Gamble, Gerard's Bridge Alkali Works (afterwards one of H.M. Inspectors of Alkali Works and subsequently editor and proprietor of the *Chemical Trade Journal*). He was the Hon. General Secretary of the Society and a vice-president. I used to chaff him about being like the Irishman, who was "never happy unless he was fighting"; and he certainly "built better than he knew." After him I should name the late Mr. Thomas Tyrer, whom I suggested would make a good Metropolitan Secretary (*cf.* his speech at Leeds, J., 1905, p. 722); and Dr. Roscoe, who became the first President.—I am, Sir, etc.,

Douglas de L. Herman.

Manchester, January 11, 1921.

PERSONALIA.

Sir James A. Walker has been nominated by the Council of the Chemical Society to succeed Sir James J. Dobbie as president.

Dr. J. N. Pring, reader in physical chemistry at Manchester University, has been appointed head of the physical chemistry branch of the research department at Woolwich Arsenal.

The Perkin Medal for 1921 has been awarded by the American Section of the Society of Chemical Industry to Dr. W. R. Whitney, director of the research laboratories of the General Electric Co.

The following appointments have been made by the Secretary for Mines:—Chief Inspector of Mines, Mr. T. H. Mottram; Deputy Chief Inspector, Mr. H. Walker; Divisional Inspector of Mines, Mr. J. Masterton; Senior Inspector, Mr E. H. Fraser.

The following have been elected officers of the Council of the American Chemical Society for 1921: President, Prof. Edgar F. Smith; Directors, Messrs. G. D. Rosengarten and H. P. Talbot; Councillors, Messrs. H. E. Howe, C. L. Alsberg, Allen Rogers, and Lauder W. Jones.

Dr. F. G. Cottrell has resigned the directorship of the Bureau of Mines and has become chairman of the Division of Chemistry and Chemical Technology of the International Research Council. His post at the Bureau of Mines has been filled by the appointment of Mr. H. Foster Bain, mining engineer, and formerly assistant director of the Bureau.

The John Fritz gold medal has been awarded to Sir Robert Hadfield for his invention of manganese steel. The medal was first given in 1902, in honour of Mr. John Fritz, ironmaster, of Bethlehem, Pennsylvania, and the award is made by a committee representing the leading American societies of civil, mechanical, metallurgical, and electrical engineers.

Dr. Henry Peile, late chairman of the Newcastle Section of this Society and chairman of the Newcastle Alloy Co., Ltd., has been appointed a Commander of the Order of the British Empire (C.B.E.) for services rendered in connexion with the war. The same honour has been conferred upon Major Sir Douglas Mawson, Head of the Explosives and Chemical Section, Foreign Trade Department.

We regret to record the death, on January 15, from sudden heart seizure, of Mr. Charles Simmonds, who had served for many years in the Government Laboratory, where he was recently promoted to the grade of Superintending Analyst. Mr. Simmonds was a chemist of wide experience; after serving in the Crown Contracts branch of the Laboratory, he was specially engaged first on steel (in connexion with the old Steel Rails Committee) and then on pottery glazes. More recently he had been working on the industrial uses of alcohol, and his work on this subject was published about a year ago, and reviewed in these columns (*cf.* J., 1920, 46 R).

NEWS AND NOTES.

FRANCE.

Industrial Notes.—*Chemical Industry.*—Owing to German competition and a general lull in demand, the situation in the chemical market remains unsatisfactory, and prices in general are falling slowly. Heavy chemicals are not materially affected by the present slump, but there are very few inquiries for special products used in dyeing and bleaching, and for textiles, soap, rubber, and plastic materials. Whereas France formerly obtained heavy chemicals from Germany, she is now sending them to that country and buying finished products instead. French buyers are obtaining indispensable chemicals from Germany rather than England, and the Government has been criticised on this account. The production of calcium carbide is still insufficient, but is to be increased by the erection of a new factory near Ugines, where 32,000 h.-p. is available from the waterfalls of the Doron; the electric steelworks "Paul Girod" is undertaking its establishment.

Minerals and Fertilisers.—The exportation of bauxite, hitherto prohibited, is now allowed to a limited extent to England and America, on payment of a duty of 25 per cent. *ad valorem*, the object being to improve the rate of exchange.

Florida phosphate has reappeared on the French market, doubtless owing to the fall in freights. In some quarters it is held very strongly that such foreign material ought not to be imported, and that France should derive supplies from her own North African colonies; yet some superphosphate works have had to close down from shortage of raw material. The tardy development of the phosphate beds in Algeria and Tunisia is variously ascribed to shortage of freight, of labour, and lack of railway material, but the true cause is probably lack of organisation at the mines. An agreement has been made to supply Italy with 500,000 tons of phosphate yearly in return for 8000 t. of pyrites and a certain amount of labour.

Opinion in Alsace is against the Government scheme for working the potash deposits, by which exploitation would be carried out by four companies; it is held that the State should do the work, that all the employees engaged in the industry should have a share in the profits, and that farmers should be granted priority in regard to supply and favoured terms as regards prices. Such concentration, it is thought, would be the best means of fighting German competition, which is expected to become very severe.

It is reported that petroleum fields have been discovered close to the French frontier in Spanish Morocco.

Metallurgy.—The general situation in 1920 was little better than that during the last six months of 1919; the same factors—shortage and high price of coal, transport difficulties, and high railway rates—continued to impede production, and hence the rolling mills were unable to quote definite prices or dates of delivery. The steelworks outside the invaded area have attained 70 per cent. of their pre-war monthly output, but the restored Lorraine works only 41·1 per cent. The total production of steel during the first six months of 1920 was 1,204,701 tons, and that of pig-iron 1,358,856 t., including 1,325,937 t. made in the blast furnace and 32,919 t. in the electric furnace.

The Comité des Forges de France, on the occasion of its fiftieth anniversary, has published an interesting work on "La Sidérurgie Française," in which, among other points, the prospects of the French iron and steel industry are discussed. It is estimated that when the devastated works of northern and eastern France are in full working order the French production, including that of the Saar district, will be 11 million tons of pig-iron and 10·4 million tons of steel, or, in the event of the Saar district being restored to Germany in fifteen years' time, 9·4 million tons of pig-iron and 8·1 million tons of steel. In 1913 production and consumption were approximately equal, viz., 5·2 million tons of pig-iron and 4·8 million tons of steel. As Lorraine and the Saar do not absorb their own production, it follows that after pre-war conditions have been established and the wants of the devastated areas fully met, there will be a good surplus available for exportation.

At the moment German competition in the metallurgical market is very active, and quotations from Germany are frequently 50—70 per cent. below the French. The reduction in the price of metallurgical coke from 175 to 135 francs per ton will enable French producers to bring their prices more into line with those of their competitors, although the latter have a decided advantage as regards price of coal and labour.

BRITISH INDIA.

Fermentation Industries.—In India, as in other countries, attention is being directed to the possibility of producing alcohol for power purposes, and the Bombay Government proposes to erect an experimental distillery. As it is, of course, undesirable to use foodstuffs for this purpose, the choice of raw materials is considerably restricted. Alcohol for burning and for industrial purposes has been manufactured on a considerable scale from the *mahua* (or *mowa*) flower, which contains a large proportion of lævulose, but the supply of this material is not very great, and the cost of collection would become serious if the scale were enlarged. The possibility is being considered of obtaining alcohol from the rice straw and husk which are available in large quantities in Burma, and especially at Rangoon, where the principal rice mills are situated.

At Nasik, in Western India, a Government factory of considerable size has been erected for the manufacture of butyl alcohol and acetone by the Weizmann process. Nasik was selected as the locality because it is a good centre for *mahua* in spite of the fact that mahua had never been used for this process. It has now been found that the most advantageous raw material is low-grade rice, unfit for human consumption, from the Rangoon rice mills. This is now being utilised with technical success, but it is doubtful whether a commercial success can be achieved because the cost of the factory was very high.

CANADA.

Glass Production.—The Canadian Libby Owens Sheet Glass Co., Ltd., is about to erect a plant at Hamilton, Ontario, with a capacity equivalent to 65 per cent. of the total Canadian importations of sheet glass. All the raw materials will be of Canadian origin, *e.g.*, soda ash from Amherstburg, salt cake from Hamilton, and silica from Cayuga, etc. It is proposed to erect another plant to supply the Western Provinces.—(*Ch. of Comm. J.*, *Dec.* 31, 1920.)

Maple Sugar.—The maple sugar industry has expanded considerably during recent years, particularly in Quebec, where the production in 1920 was about 13,393 long tons, as against 4911 t. in 1911. Similarly, the output in Ontario was 3125 t., compared with an average for previous years of 2232 t.; in Nova Scotia and New Brunswick, the only other provinces producing maple sugar, the production was, roughly, 223 t. The exports of maple sugar also show an increase, the total in 1919-20 being 1788 t., which compares with 653 t. in 1914-15.—(*Official.*)

Discovery of Silver.—It is reported that extensive deposits of silver have been discovered near Keno Hill, in the Yukon territory, and it is hoped that their exploitation will compensate for the declining production of gold.—(*Official.*)

UNITED STATES.

The Dye Industry and the Longworth Bill.—Dye manufacturers in the United States have had to face a similar crisis to that which recently threatened British manufacturers, and they are looking forward to the speedy enactment of the Longworth Bill, which passed the House of Representatives in September, 1919, but has since been held up by the Senate. The Bill provides that only such dyes shall be imported as are not made in the country "in adequate quantity, of good quality, and at reasonable prices." It was primarily intended that the Act should be administered through a joint committee of producers and consumers, but it was subsequently decided to entrust this work to the Tariff Commission. After conferences between this Commission and the Senate Committee on Finance, it was agreed to publish a list of dyes which might be imported in order to avoid inconvenience to the consumer. The Senate Committee reduced the higher tariff rates proposed in the Bill, thus making the embargo less rigorous, and in this amended form it recommended the Senate to adopt the measure. However, when the Bill came before the Senate last spring it was "talked out" by its opponents.

The American Chemical Society has issued a bulletin urging strongly that the Bill be considered and passed without delay. Among the arguments advanced are, (1) a self-contained and independent dye industry is a strong weapon for national defence; (2) large quantities of German dyes are now coming on the American markets; (3) the development of the home industry is being crippled by the uncertainty of legislation; projected extensions of plant have been postponed, research staffs reduced, and much of the capital invested in laboratory plants and apparatus ($100,000,000) remains unremunerative. Further procrastination is condemned not only by the large dye firms, but also by the small manufacturers, on behalf of whom it was declared in the Senate that they would be the first to go under in the price war which would ensue if adequate legislation were not enacted. The home dye industry is now able to meet 85 per cent. of the needs of the country; the remaining 15 per cent. includes the special dyes which only a fully developed industry can be expected to produce.

The Dye Industry in 1919–20.—According to a report issued by the Bureau of Foreign and Domestic Commerce, the United States now possesses a dye industry capable of meeting all home demands. The tendency to consolidate American dye enterprises has not only increased consumption but also developed foreign trade. The value of the aniline dyes exported during the year ended June 30, 1920, viz., $17,130,397, represented an increase of 68 per cent. over that of the previous year. Imports of alizarin and alizarin dyes amounted to 115·1 tons ($103,266), compared with 5·3 t., valued at $13,286, in 1918–19, practically all of which was derived from the United Kingdom; it is reported, however, that one of the largest American makers can now supply certain alizarin colours. Imports of other finished coal-tar dyes rose from 863·4 t. ($2,753,116) to 1224·1 t. ($3,775,216), or an increase of 44 per cent. Switzerland has replaced Germany as the chief source of imported coal-tar colours; the United Kingdom supplied 275·3 t., worth $609,238, in 1919, and 249·1 t., worth $567,258, in 1920. Imports of natural indigo declined from 444·6 t. ($1,242,855) in 1919 to 56·5 t. ($165,332) in 1920, but that of synthetic indigo increased from 265·2 t. ($308,582) to 452·7 t. ($530,285); it is considered unlikely that natural indigo will be able to compete with the synthetic product. Owing to the need of statistical data concerning the foreign trade in coal-tar colours, a new import classification has been drawn up which takes effect as from January 1, 1921.—(*Bd. of Trade J., Dec.* 9. 1920.)

Sodium Compounds in 1919.—The total production of manufactured sodium compounds was 9,393,749 short tons, valued at $121,204,219 in 1919, compared with 10,199,493 t., worth $142,788,535, in 1918. Of sodium salts derived from natural sources 7,093,138 t. was produced in 1919, against 7,262,797 t. in the previous year. Imported sodium salts showed a very great decrease, viz., 522,356 tons, compared with 2,111,725 t. in 1918, but imports of sodium cyanide, ferrocyanide, and sulphide notably increased. The exports, valued at $18,545,420, consisted chiefly of common salt (119,416 t.), caustic soda (82,118 t.), soda ash (50,481 t.), washing soda (5,563 t.), and sodium silicate (12,150 t.); those of soda ash decreased greatly, but that of caustic soda increased. The substitution of sodium compounds for potassium compounds, initiated during the war, continued during 1919.

Production of sodium and sodium compounds in the United States in 1919.*

	Quantity Short tons
Sodium acetate	2426
Sodium benzoate	126
Sodium bicarbonate	134,962
Sodium bichromate	26,526
Sodium bisulphite and sulphite	11,846
Sodium bromide	499
Sodium carbonate—	
Soda ash	961,054
Monohydrate and sesquicarbonate	30,796
Sal soda	80,090
Sodium chlorate and sodium perborate	1210
Sodium chloride—	
Salt in brine	2,809,000
Rock salt	1,637,300
Evaporated salt	2,618,200
Sodium citrate, tartrate, bitartrate	33
Sodium cyanide, peroxide, iodate	9148
Sodium ferrocyanide	3437
Sodium fluoride, acid sodium fluoride, sodium fluosilicate	811
Sodium hydroxide (caustic soda)	355 466
Sodium iodide	12
Sodium nitrate (refined)	8040
Sodium nitrite	676
Sodium phosphate (including all sodium phosphates)	14,760
Sodium silicate	300,138
Sodium sulphate—	
Salt cake	134,685
Glauber's salt	42,087
Nitre cake	83,402
Sodium sulphide	45,448
Sodium tetraborate (borax)	28,518
Sodium thiosulphate (hyposulphite)	32,212
Miscellaneous sodium compounds	841
Total	9,393.749

* For production in 1917 and 1918 *cf.* J., 1920, 8R.

In the above returns the production of sodium cyanide is combined with that of peroxide and iodate in order not to reveal the production of individual firms. Sodium cyanide is now being supplanted by a product, presumably calcium cyanide, made by heating calcium cyanamide with salt to a high temperature and quickly cooling the melt. The reaction is conducted continuously in electric furnaces with conducting hearth and a single suspended electrode; it is used directly in the extraction of gold and silver and for making sodium ferrocyanide and hydrocyanic acid.

The production of caustic soda given in the table does not include that made in soap works. Many pulp and paper mills also make caustic soda for their own use.—(*U.S. Geol. Surv., Nov.* 16, 1920.)

Foodstuff Preservation with Condiments.—The Glass Container Association of America has published a monograph by K. G. Bitting on the "Effect of Certain Agents on the Development of Some Moulds," in which the observations of some fifteen

years are recorded. The work has special reference to the use of spices or other condiments as preservatives for foodstuffs, and in addition to containing numerous tables, it is profusely illustrated with photomicrographs showing the effect of many materials upon typical moulds.

New Use for Mercury.—The utilisation of mercury vapour for the production of power is being investigated in the United States, the object being to increase the range of temperature through which the heat from the fuel may be converted into power. The mercury is vaporised in a special boiler at about 10 lb. gauge pressure and used to drive a turbine. The exhaust from this turbine is condensed in a form of surface condenser, which produces steam from the cooling water, and the steam is utilised to drive another turbine, the condensed steam in this case being used as cooling water for the mercury condenser. It is claimed that the use of this device in a modern power station would increase the capacity by about 60 per cent., while increasing the fuel consumption by only 15 per cent., and trials with over a 1000 k.w. on the mercury turbine are stated to have fully realised the economies predicted.—(*Power, Oct.* 27, 1920.)

SOUTH AFRICA.

Mineral Output in 1919.—The Annual Report of the Secretary for Mines and Industries, 1919, gives the mineral production for that year and for 1918 as follows:—

	1919.	1918.
	Tons.	Tons.
Coal	10,266,135	9,877,325
Copper	4,885,319	6,874,859
Tin	1,630,168	2,206,042
Antimony	32,000	99,055
Arsenic	8,120	17,785
Lead	756,000	161,600
Manganese	155,000	544,250
Tungsten	*4,469	18,880
Asbestos	3,932,077	3,674,053
Corundum	178,587	3,875,526
Graphite	85,511	78,974
Iron pyrites	5,532,234	4,630,000
Magnesite	1,024,000	832,500
Mica	2,951	5,089
Mineral paints	239,809	735,556
Soda	52,050	764,340
Talc	756,750	670,250
	Fine oz.	Fine oz.
Gold	8,331,651·142	8,418,379·029
Silver	891,303·635	877,522·147
	Carats.	Carats.
Diamonds	2,588,017·06	2,537,360·16

*Mostly contained in other ores.

The low-grade gold mines on the Rand are stated to be in a serious position, and labour troubles are reducing the output of the more productive properties. Attention is now being concentrated on base metals and minerals, such as iron ores, asbestos, corundum, mica, and, to a lesser extent, salt, lime, gypsum, soda, magnesite, and graphite. —(*Bd. of Trade J., Jan.* 6, 1921.)

JAPAN.

The Dye Industry.—The U.S. Bureau of Foreign and Domestic Commerce has received information from Tokyo to the effect that the Japanese dye industry cannot compete with German or American manufacturers, even with the help of the new import duty of 35 per cent., owing to lack of technical skill in their production and of a home supply of intermediates.—(*U.S. Com. Rep., Nov.* 23, 1920.)

Imports of Dyestuffs in 1920.—Since the end of the war the new Japanese dyestuffs industry has suffered to such an extent from the revival of European competition, that in March, 1920, 72 works, or 65 per cent. of the whole industry, had to close down. Concurrently the importation of dyes rose from 130 tons in January to 262 t. in May, and fell during the industrial crisis in June to 165 t., the total for the six months ended June, 1920, being 1025 t., as against 226 t. in the same period of 1916. The imports of European and American dyestuffs have steadily increased since 1916, although there was a large decrease in 1917. The average price of dyestuffs in Japan in 1920 was 4·75 yen per kin (9s. 8¼d. per 1·32 lb. at par value).—(*Z. angew. Chem., Dec.* 24, 1920.)

AUSTRALIA.

The Iron-Ore Deposits at Yampi Sound, Western Australia.—The Queensland Minister for Mines announces that his Government has decided to exercise the option of purchase which it holds over the vast iron-ore deposits in Cockatoo Island, Yampi Sound (*cf.* J., 1920, 218 R), with a view to establishing State iron and steel works in Queensland. The Minister stated that the opinion of the manager of Messrs. Armstrong, Whitworth and Co. (Mr. Cooper) was that the manufacture of steel from ore as rich as that at Yampi would be extremely easy.—(*Official.*)

Gold Mining, etc., in Western Australia.—The Imperial Mineral Resources Bureau reports a noteworthy development on the abandoned Golden Dream lease, about one mile north of Hannan's Reward mine, Western Australia. An auriferous lode has been struck and driven on for 60 ft. over an average width of 2 ft. 6 in., and a trial crushing gave 95 oz. of gold from 88 tons of rock, with 5 dwt. per ton in the sands.

The production of gold at State Batteries since the date of inception to August 31, 1920, has now reached a total value of £5,230,839, made up as follows:—Tons of ore milled, 1,266,431·69; production by amalgamation £4,379,655·52; by sands treatment £634,354·64; by slimes treatment £207,475·47; and by residues £9353·37. In addition, the State tin-treatment plants have produced by black tin £92,120·93, and by residues treatment £572·32, making a total mineral value from all sources of £5,323,532·25.

GENERAL.

Research in the Brewing Industry.—An editorial in the current issue of the *Journal of the Institute of Brewing* expresses regret that the activity in brewing research which marked the halcyon days of O'Sullivan, Horace and Adrian Brown, Heron, and Morris, has not been sustained in recent years, and ascribes the lack of progress mainly to the restrictive influence of State supervision. The fact that the brewing and distilling industries are valuable sources of revenue to the State hampers initiative, stereotypes processes, and fosters empiricism at the expense of scientific advance. The Amylo process of alcohol production, for example, is not permitted in this country because of a statutory regulation which prescribes that the strength of distillers' worts before fermentation must be ascertained by the saccharometer, a method which is not practicable in the process named.

In order to promote and develop organised research, the Institute of Brewing has drawn up a comprehensive scheme, and has succeeded in raising a capital sum which will allow of £5000 per annum being devoted to this purpose. Investigations on the breeding and cultivation of hops have been undertaken at the South-Eastern Agricultural College at Wye and at the Malling Fruit Research Station, whilst experiments on the drying of hops and on the effect of manurial treatment on their growth have been made possible by the generosity of private donors. Concomitantly with these researches Prof. F. L. Pyman, at the Manchester College of Technology, is to investigate those constituents of the hop which determine its preservative and antiseptic properties; and work on barley is also to be taken in hand. Arrangements have been made for the investigation of the suitability of various species of oak for cask-making (suppli

from Memel being no longer available) at the Imperial College, South Kensington, where Prof. F. B. Schryver and Prof. P. Groom will attack the problem from the chemical and botanical sides respectively. The Institute has also made due provision for the encouragement of research by individual private workers.

The Science of Nutrition.—The Huxley Lecture delivered by Prof. Gowland Hopkins at Charing Cross Hospital Medical School on November 24, 1920, was devoted to a review of the striking modifications which the theories of animal nutrition have undergone during the last twenty years.

At the close of last century the problems of human nutrition were being more and more regarded from the standpoint of energetics, and dietaries were usually considered solely on the basis of nitrogen content and calorific value. Although it is true that many of the foundations of the science of nutrition were laid by investigators who regarded the problems they attacked in this manner, there was a tendency on the part of many to carry this conception too far and to neglect the influence of other factors. Rubner, to whom we owe so much of our knowledge of the energy requirements of the animal body, was led away in this manner, and gradually developed a theory which disregarded, in one sense, the significance of the chemical composition of the diet and the material changes which occur in the body, and gave sole prominence to the calorific values of the constituent foodstuffs. The law of Isodynamic Equivalence, propounded by Rubner, states that he living tissues demand energy alone, and from is works one infers that considerations of energy xchange are alone adequate to explain such henomena as growth, body size, and length of ife. It does not require a very deep examination f his views to show how misleading they may be, nd, indeed, have been. If fat and carbohydrate re interchangeable as sources of energy for the nimal tissues, as follows from Rubner's law, it hould be possible to derive the whole energy supply rom a dietary of fat. Such an extreme case is one of he many examples where the theory fails, for it is ell known that such a diet causes a definite breakown in the internal metabolism of the body with he production of the abnormal condition known s ketosis.

Closely following the theories of Rubner we have he system of nutrition introduced by Prof. von irquet, of Vienna, who evaluates dietaries in erms of a unit called the "Nem," which is the nergy supplied by the combustion of the conituents of 1 c.c. of milk. Here we have a ractical system in which the chemical details f the diet are disregarded, and yet one which being employed on a large scale to-day in entral Europe in the organisation of the relief eding of nearly a quarter of a million children in ienna on behalf of the Red Cross organisation. uch systems as these are now being vigorously ttacked by investigators, mainly of the Englisheaking races, who hold that the chemical composion of the diet is as important as the calorific take. It is now established that the character of e protein supply is all important to the animal dy, and that the biological value of the proteins ay show wide variations, which can be traced to eir content of certain indispensable amino-acids. rther, the discovery of the vitamins and recent rk in this wonderfully interesting field of rearch have demonstrated that nutrition and health ay fail even when an animal is consuming a etary adequate as regards protein, calories, and lts unless ample supplies of these unidentified cessory factors are present. Rubner and hi llowers would regard energy supply as the one ential limiting factor in nutrition, but it must now be recognised that there are many factors which may act in this manner. In this country and America there remain few who do not acknowledge this to be true, but in Central Europe the older theories still hold their ground. They are, however, being attacked in a manner that promises to demonstrate their inaccuracy. Dr. Harriette Chick and Dr. Elsie Dalyell, under the auspices of the Lister Institute and the Medical Research Council, are now in Vienna, where in two adjacent wards of the hospital of von Pirquet the new theories are being tested against the "Nem" system under rigidly controlled parallel conditions. As Prof. Hopkins remarked, "the enterprise is unique in its occasion, in its international character and in the high qualifications of those who are conducting it." One cannot help foreseeing that this experiment will show how important to practical medicine are recent advances in the science of nutrition.

The Sweetness of Saccharin.—The sweetening powers of saccharin and of its hydrated sodium salt are conventionally accepted at the fixed values of 550 and 420, respectively, compared with that of refined beet sugar, but recent investigations by Prof. Th. Paul have shown that the sweetness is dependent upon the concentration of the saccharin solution tested; it increases at a slower rate than the concentration. Thus the sweetness of the sodium salt (in concentrations corresponding to 2—10 per cent. sugar solution) was found to vary between 200—700 times that of sugar, and not to be 420 times, as generally accepted. It was also found that the sweetness of an aqueous solution containing saccharin and other artificial sweetening agents was approximately equal to the sum of the sweetening powers of the constituents. These results should assist those concerned in estimating the amount of sweetening agent required for any particular foodstuff.—(*Schweiz. Chem.-Z., Nov.* 30, 1920.)

Proposed Drug Monopoly in Sweden.—There are grounds for believing that the Swedish Government intends to create a monopoly in the manufacture of pharmaceutical preparations, and possibly also to nationalise the whole industry. According to the present law, the manufacture of medicinal preparations by druggists is restricted to that of certain articles, but in recent years almost all descriptions have been manufactured in a large number of private laboratories, and effective control has been completely lacking. It is provisionally planned that a new central institution shall take over all existing privately-owned works, but that individual pharmacists shall be free to manufacture for themselves or to purchase from the institution. Owing, however, to the superior economy of large-scale production, it is considered certain that in nearly every case druggists will be driven to adopt the latter course. The institution mentioned will be established by a new subsidiary company of the Wine and Spirit Central Organisation in Stockholm, which will have a capital of 5 million kronor (£281,250 at par), and every Swedish pharmacist will be summoned to take shares, the Central Organisation retaining a majority. The works of the A.B. Astras Fäbriker in Söderfälje will then be acquired and manufacture proceeded with. Finally, an opportunity will be given to the State to acquire a controlling interest in the undertaking.—(*Chem. Ind., Nov.* 17, 1920.)

The Porcelain Industry in Norway.—All porcelain used in Norway for technical purposes formerly came from Germany, but war conditions gave the spur to the development of a home industry. The Norsk Teknisk Porzelänsfabrik, Frederikstad, is now in a position to supply technical porcelain ware in great variety, more particularly electrical insulating ware, and to hold its own against foreign competition. The company was formed during the

war, began to produce regularly in November, 1919, and now commands a capital of 1·1 million kronor (about £62,000 at par). Norwegian felspar and quartz, and German kaolin are the raw materials employed, and as the factory has ready access to the harbour, transport arrangements are very favourable. It is candidly admitted in Norway that the installation and manufacture would have been impossible but for the help of German technologists and workpeople, who have been employed since the beginning. German labour is used for all difficult work, and the technical director is a German who for a long time held a prominent position in a leading German factory.—(*Z. angew. Chem., Dec.* 10, 1920.)

Cost of a German Degree Course in Chemistry.—The present cost of a four-year course (eight semesters) in chemistry is estimated to be about 6000 marks (about £300 at par, now £22—27), exclusive of the cost of materials required for the "Doktorarbeit," and of the fees payable upon graduation (500 mk.). The cost is distributed as follows:—First semester, lectures 250 mk., books 200 mk.; second semester, lectures 250 mk., books 100 mk.; third semester, qualitative analysis, practical physics, etc., 400 mk., materials 450 mk.; fourth semester, qualitative and quantitative analysis, practical physics, etc., 400 mk., books 100 mk., materials 400 mk.; fifth semester, quantitative analysis, special and general lectures, organic preparations, 350 mk., books 150 mk., materials 700 mk.; sixth semester, organic chemistry 350 mk, books 100 mk., materials 700 mk.; seventh semester, "Doktorarbeit," roughly 300 mk.; eighth semester, 300 mk. Thus the cost of University fees is about 2600 mk., books 650 mk., and chemicals, apparatus, etc., 2250 mk.—(*Chem.-Z., Nov.* 13, 1920.)

Chromium Ore in Russia.—The chief deposits of chromium ore in Russia are on the eastern slopes of the Ural mountains, and although little is known about them, their large number and their proximity to metallurgical centres should lead to development when conditions permit. There are no data available concerning production, but it is known that ore has been obtained from 20 or 30 small mines by means of primitive methods. Chromium ore is stated to occur in abundance on the north-east shores of Lake Koktcha, Government of Erivan, Transcaucasia, and also along the Gazimur River, near the Kultuminsk silver-lead mines in Transbaikalia.—(*U.S. Com. Rep., Sept.* 20, 1920.)

Possible Sources of Wood-Pulp in Chile.—The utilisation of the timber resources of Chile should receive increased attention as the more accessible wood-pulp material ceases to be available. Analysis of certain woods and reeds by the soda process has given the following results:—*Olivillo* gave 38 per cent. of a dark pulp, difficult to bleach, but quite suitable in its unbleached state for the manufacture of wrappings. The average length of the fibre was 2·15 mm., and a sheet 0·0044 in. thick showed a bursting strength of 23 lb. per sq. in. *Coigue* yielded 42 per cent. of a pulp readily bleached; the fibres were short (0·86 mm.), but in conjunction with sulphite pulp it could be used for the production of printings. *Lingue* closely resembles Coigue, but gives slightly longer fibres (1·11 mm.). *Quilla.*—This reed occurs abundantly and can be harvested annually; it gave a pinkish-coloured pulp with an average length of fibre of 2·22 mm., and could be used unbleached for newsprint. The bleached pulp could be used without the addition of sulphite pulp for the production of light printings. There are other woods said to be equally well or better suited for pulp-making, such as the Araucanian pine, which grows abundantly and rapidly and gives a dark-coloured pulp, with an average fibre length of 2·36 mm.—(*U.S. Com. Rep., Oct.* 22, 1920.)

REPORT.

Report on the Trade, Industry and Finance of Morocco. *Department of Overseas Trade. London: H.M. Stationery Office.* 1920. [Cmd. 975. 1*s*.]

The French Protectorate of Morocco has numerous natural resources, many of which are either unutilised or are being developed on an experimental scale. Industry is now developing freely under conditions closely resembling those which existed before the war, and, with the exception of certain agricultural produce, the export trade is unfettered by restrictions. The mineral resources are still undeveloped, but important oil-fields and phosphate beds will probably be exploited in the near future. Industrial development, hitherto very backward, has made rapid strides since 1914; factories have been erected for the manufacture or preparation of cement, lime, palmetto-palm fibre, meat and other foods, as well as flax-spinning and olive-oil mills, electrical power stations, and a large modern slaughter-house with by-products factory. Progress is reported in the cultivation of flax, and prospects of producing spun flax and hemp are considered very hopeful; however, with the exception of wool and the palmetto palm, raw materials are not abundant. There has been a great shortage of fuel, and skilled labour is scarce. Exports in 1919 included:—Linseed, 15,680 tons (£840,952), and hides and skins, 3246 t. (£782,783). Imports consisted chiefly of building materials (*e.g.*, cement 3794 t.), cotton textiles, sugar (43,884 t.), candles (3579 t.), soap, kerosene, and gasoline; there is a large demand for cement, glassware, gasoline, kerosene, and coal.

The resources of the Tangiers Zone are confined to agricultural products. There are no railways in the area, but work has been started on a line between Tangiers and Fez. Exports in 1919 were valued at £289,669, including beeswax (£4310), and skins and hides (£192,117); imports were valued at £1,563,650. Great Britain has retained its prewar predominance in the import trade of many articles, *e.g.*, candles and soap, and has taken the place of France as the chief source of supply of paints, but has lost practically the whole of the trade in vegetable oil to Spain. Good openings are available for British exporters of building materials and window glass, cement, fertilisers, glass and china.

The agricultural prospects of the Spanish Zone of Morocco are good; the palmetto palm is very abundant, and its fibre and leaves are used by the natives for making baskets, mats, etc.; extensive cork oak forests exist in the unpacified areas, and a great future is anticipated for the cultivation of olives. The occurrence of ores of iron, copper, zinc, lead, silver, and other minerals is known with certainty, but adequate surveys of their nature and extent have hitherto been impossible owing to the unsettled state of the country. Three iron-ore and one lead-and-zinc mine are being worked in the Melilla district, the most important of which is the iron-ore mine of the Espanola Minas del Riff company, which has a monthly output of 15,000 to 20,000 tons assaying Fe 63%, SiO_2 5%, and a low phosphorus content. An output of 50,000 tons a month is considered possible. From the Navarette mine of the Setolazar company, 61,000 t. of ore was shipped to the United Kingdom in 1918, and the annual output is expected to reach 150,000 to 200,000 t.; the ore averages 57·5 per cent. of iron, but is rather high in phosphorus. The Alicanta company has produced about 800,000 t. of manganiferous iron ore since 1915; its deposit is superficial, but is estimated to contain up to one million tons of ore with about 55 per cent. of iron. The Afra lead

and zinc mine is worked by the Norte Africano company, which has produced a maximum yearly output of 1500 t. of galena. This mineral is of high grade, but non-argentiferous; the zinc ore is calamine with about 32 per cent. of zinc. A new washing and concentrating plant of large capacity has been installed at the mine by a German firm, but has not yet been used. Numerous deposits of iron ore are said to occur in the unpacified zone, and other reported occurrences are lead, copper, antimony, and petroleum. Both the export and the import trade are almost entirely in Spanish hands; in the former England is badly handicapped by absence of direct shipping communications. The exports from Tetuan in 1918 included hides and skins, tanned hides, tamarisk gall, fullers' earth, linseed, virgin wax; and among the imports of British origin in 1918 were ultramarines, perfumery, soap, candles, linoleum; and in 1917 refined sugar, linseed oil, sarsaparilla, varnishes, ochres and ultramarines, perfumery, soap, candles, glass, and matches.

The report contains a large sketch map of the country, appendices giving statistics of trade, revenue, prices, etc., and reports on minerals submitted by the Imperial Institute to the Department of Overseas Trade (*cf.* J., 1920, 382 R).

OFFICIAL TRADE INTELLIGENCE.

(From the Board of Trade Journal for January 13 and 20.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent the U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number:—

Locality of Firm or Agent.	Materials.	Reference number.
ustralia ..	Perfumery	80
" ..	Paint (oxide of iron)	*412/20/7/392
ritish India ..	Glass, crockery, porcelain, soap, perfumery	83
		83
anada	Galalith wares	85
"	Paper mill materials	91
"	Soap, toilet preparations	42
"	Heavy chemicals, dyes	43
"	Asbestos card	†

* The Official Secretary, Commercial Information Bureau, Australia House, Strand, London, W.C. 2.

† The Canadian Government Trade Commissioner, 73, Basinghall Street, London, E.C. 2.

MARKETS SOUGHT.—A Canadian firm wishes to dispose of 10,000 tons of fertilisers (ammonia and phosphoric acid compound).

A Canadian company invites applications for quantities of "Stellite" (high-speed steel).

[Inquiries to the Canadian Government Trade Commissioner.]

TARIFF, CUSTOMS, EXCISE.

Australia.—The import of calcium carbide is prohibited except under licence as from Dec. 2, 1920.

The prohibition of the export of pig-iron and manufactures of metals has been revoked.

Egypt.—Among the articles that may be exported without export licence (under certain conditions) are coconuts, sweetened condensed milk, dyes, gold leaf, nuts (except arachis), starch, edible fats, and margarine.

Fiji.—The export of copra is now permitted without licence.

France and Algeria.—The "coefficients of increase" on certain articles have been increased. Articles affected include glucose, chicory, vinegar, aluminium powder, iron shavings, bronze powder, soap, yeast, syrup, certain kinds of leather, and many chemicals and drugs.

Germany.—Among the articles hitherto temporarily admitted duty free which must now pay the prescribed rates of customs duty as from January 1 are vegetable wax, beeswax, spermaceti, copper sulphate, zinc oxide, ammonium nitrate, lead nitrate, casein, certain kinds of leather, dissolved rubber, and soft rubber paste.

Italy.—Certain building materials, including cement, may be imported duty free until June 30, 1922.

Latvia.—Among the articles that may be imported free of restrictions are medicaments, cast iron, steel, copper, white metals, naphtha, engine oil, fertilisers, tanning materials, sole leather, window glass, and industrial chemicals.

Articles the import of which is prohibited include, *inter alia*, beer, gold, silver, bronze, glass and porcelain (with some exceptions), perfumery, toilet soap, yeast, syrup, certain kinds of leather, and certain pharmaceutical preparations.

The import of all other goods is allowed under special licence.

Netherlands.—Export prohibitions have been removed from acetone, bone meal, Chinese wood oil, coal-tar dyes, gypsum, lime, limestone, dyeing woods and extracts, medicines, petroleum, pyrites, rosin, asphalt, shellac, train oil, wood tar, pitch.

Recent customs decisions affect solid fats, diphenylmethane, rubber yarns, bromoform, beta-naphtholmethyl ether, beta-naphtholethyl ether.

Norway.—The prohibition of the export of salt has been withdrawn.

Poland.—Among the articles that may be imported without permits are cocoa, alcohol, albumin, fertilisers, glue, animal fats and oils, wax, skins, certain kinds of leather, cork, certain oil seeds, certain building materials and ceramic wares, tar, pitch, anthracene, benzene, phenol, rosin, asphalt, gums, rubber, many chemicals, ores, metals and metal wares, cellulose, and certain kinds of paper. [The list is very long and is given in full in the issue for January 20.]

South Africa.—Opium and preparations thereof may only be imported under certain specified conditions with the permission of the Secretary for Public Health.

Trinidad.—All goods entitled to preference under the British Preferential Tariff must be accompanied by a certificate of origin. [January 13.]

Tunis.—The import of binder twine and sulphur is now permitted.

Turkey.—The export is prohibited of, *inter alia*, sugar, certain building materials, charcoal, quinine, neosalvarsan, aspirin, gold, silver, and nickel.

TRADE NOTES.

BRITISH.

St. Helena in 1919.—Agriculture generally has been much neglected in favour of flax-growing, which is making good progress. There was, however, a short supply of fibre, as small and immature leaves had been harvested to take advantage of the high prices. The output from the Government mill was 40½ t. of fibre and 27 t. of tow, and two private mills produced 410 t. of fibre and 115 t. of tow. Imports and exports were valued at £44,084 and £30,878, respectively, the latter including 603 t. of fibre and tow worth £27,108. The increased area devoted to flax has led to a shortage of foodstuffs, which has had serious consequences. (*Col. Rep.—Ann., No.* 1039, *Aug.*, 1920.)

Turks and Caicos Islands in 1919.—The trade of the Turks and Caicos Islands improved in 1919, the imports being worth £38,343 and the exports £33,554, as compared with £39,276 and £25,594, respectively, in 1918. Exports of salt, valued at £24,117, showed a decline owing to competition from accumulated stocks of salt in the Mediterranean, and lack of freight. Large stocks of salt —over 2 million bushels—were on hand at the end of the year. The cotton exported amounted to 15 bales of lint and 94 bags of seed, worth £580. The development of the production of cotton, said to be of high quality, is promising, as an estate of 8000 acres in the Middle Caicos has been leased to an American company for cotton-growing.—(*Col. Rep.-Ann., No.* 1042, *Oct.*, 1920.)

FOREIGN.

Chemical Trade and Industry in Argentina.—Several chemical factories which were started during the war have had to close down on account of inability to face foreign competition, and, generally speaking, the production of chemicals is small and inefficient.

Three firms manufacture sulphuric acid (53°—66° Bé), using sulphur from Italy (by preference), Chile, and the United States; chemically pure sulphuric and hydrochloric acids are produced, but only commercial nitric acid. In spite of the difficulty of transporting sulphuric acid over long distances through the tropics, local manufacurers do not find it easy to compete with foreign exporters. Acetic acid and vinegar are made in the country, but glacial acetic acid is imported. Two firms are producing, near Cordoba, acetate of lime, lead acetate, acetic acid and acetone by the distillation of wood of the algarrobo tree, but these products have to be marketed at prices higher than those imported owing to the high cost of working on a small scale. Practically no tartaric acid is made in the country, but the possibilities are well worth investigating. There is a demand for both tartaric and citric acids, preferably in the form of crystals. Importations of carbolic, boric, carbonic, hydrofluoric, and tannic acids are small. Imports of alum have declined from an average of 6300 tons in 1913–16 to 490 tons, and are now derived mainly from the United States. Liquefied ammonia is in demand for refrigerating plants, about 540 t. being imported annually, of which 90 per cent. is supplied by the United States. The yearly demand for industrial arsenic is about 250 t., although in 1919 more than double this amount was imported, again mainly from the United States. The demand for calcium carbide has decreased from 9000 metric tons in 1913 to 3000 t. in 1919. Glucose is in great demand, the imports averaging 2100 t. per annum. There is a small but insufficient production of electrolytic bleaching powder, and the annual importation averages 680 t. The imports of other chemicals in 1918 were:—Aluminium sulphate, 1155 t.; alums, 490 t.; anhydrous ammonia, 540 t.; arsenic compounds, 250 t.; boric acid, 55 t.; barium sulphate, 2024 metric tons; copper sulphate, 1740 t.; iron sulphate, 10 t.; magnesium sulphate, 676 t.; glycerin, 110 t.; paraffin wax, 1811 t.; and rosin, 14,100 t. Most of these chemicals are obtained from the United States, but the requirements in sheep and cattle dips, some 7500 t. per annum, are derived almost entirely from Great Britain; stearine, tallow and similar products are obtainable locally. There is a large demand for disinfectants, veterinary remedies, tar oil, carbolic acid, serums, and drugs in general.

The first paper-pulp factory established in the country was expected to start operating in September last. The mill, situated near Barranqueras on the Parana river, and under German-Argentine control, utilises a perennial bog grass known as "paja brava," and has a capacity of three tons of strawboard per day. The plant will in time be increased in order to furnish a larger output of a better quality pulp. There is a good field for the wood-pulp industry in northern Argentina, as there is an abundant supply of suitable raw materials and a ready market for the products.

An Argentine company is now producing on a commercial scale goods made from flax-straw waste. The process used is new, and it is claimed that the product is equal or superior in colour, elasticity, length of fibre, and resistance, to fibres retted by the old methods, which required many days' time, as compared with less than half-an-hour by the new method. The estimated quantity of linseed straw available in Argentine is 5·4 million tons annually, and except for the small amount (25 tons per day) used by the company, the whole of it is burned.—(*U.S. Com. Rep., Nov.* 2, 18, 19, 27, 29, *Dec.* 2, 1920.)

Paraguay in 1919.—The republic of Paraguay has a population of over a million, but the buying capacity for foreign goods is limited to not more than a fifth of this number. Cattle raising, meat packing, agriculture, the production of quebracho extract, and some lumbering constitute the chief industries. Cotton of good quality and sugar are also produced but are not exported. The exports in 1919, worth about £2,963,223, included:—Essential orange oil, 38 metric tons; quebracho extract, 32,876 t.; and 256,958 hides. Argentina and Spain took 56 and 10·8 per cent. of the exports respectively. The imports, valued at £3,167,194, included chemicals, drugs, mineral oils, and paints valued at £161,099, and china, earthenware, and glassware worth £25,002. Of the total imports, Argentina supplied 42·8, England 24·7, and the U.S.A. 17 per cent.—(*U.S. Com. Rep., Suppl., No.* 48*a*, 1920.)

Foreign Company News.—*France.*—The capital of the Société Chimiques des Usines du Rhône is to be increased from 3,200,000 to 21,600,000 fr. by the issue of 184,000 new shares of 100 francs each; that of the Cie. des Talcs de Luzenac from 3 to 5 million fr.; and that of L'Azote Français from 1 to 5 million francs. During the year ended June 30, 1920, the Stéarinerie et Savonnerie de Lyon made a net loss of 385,386 fr., owing to the unsettled state of the market; its capital is now 8,000,000 fr. The Caoutchouc de Sumatra Cie. produced 435 metric tons of rubber during the year ended June 30, 1920, and made a net profit of £10,436; the output of the plantations is to be reduced by 25 per cent.—(*Rev. Prod. Chim., Dec.* 31, 1920.)

Sweden.—The adverse effect of high production costs on the Swedish chemical industry (*cf.* J., 1920, 382 R) is further illustrated by the collapse of the A.S. Norsk Kemikalia of Oesterdalen. The company proposed to produce charcoal, tar, turpentine, wood spirit, and pharmaceutical chemicals, but owing to the excessive cost of construction, wages and raw material, it decided to go into liquidation while its share-capital was still intact. —(*Schweiz. Chem.-Z., Nov.* 9, 1920.)

REVIEWS.

'HE DETERMINATION OF HYDROGEN IONS. *By* W. MANSFIELD CLARK. *Pp.* 317. (*Baltimore: Williams and Wilkins Company.* 1920.) *Price, including postage, U.S.A.* $5, *other countries* $5.50 *net.*

A book on the determination of hydrogen ions in he English language should find a welcome among orkers in widely dispersed branches of chemical nquiry and application. It was known to the older hemists that numerous chemical processes comrising particularly those of importance to the iological sciences were dependent upon the 'degree" of acidity or alkalinity of the media in which they took place, and it was also known that his degree was not amenable to estimation by irect titration, but was conditioned by the trength of the acids and bases present. In all hese cases the determination of hydrogen-ion conentration furnishes a quantitative basis of inestigation. Starting from the groundwork of the onic theory, the subject under review, after having een worked out mainly in Ostwald's laboratory, as very greatly developed, especially in its biogical applications, in Sorensen's laboratory in openhagen, and is now being vigorously proseuted in its many ramifications, particularly in merica.

The author of the present work, who is engaged n the research laboratories of the Dairy Division f the U.S. Department of Agriculture, and has imself contributed notably to the advancement of he subject, has here presented a book which furishes a complete guide both to the theoretical and he practical side of hydrogen-ion determination. 'he main contents of the book include:—(1) An ntroduction, comprising a full theoretical disussion of acid and base equilibria, the p_H scale of cidity and alkalinity, buffer action, etc.; (2) a umber of chapters dealing with the colorimetric etermination of hydrogen-ion concentration, the heory and application of indicators, the preparaion and use of buffer solutions, protein and salt rrors, etc.; (3) several chapters dealing with the lectrometric method of hydrogen-ion determinaon, the theory of the hydrogen electrode, potential ifferences at liquid junctions, the apparatus and echnique required for electrometric measureents, the sources of error, the relation of ydrogen electrode potentials to reduction potenals etc.; (4) a chapter on supplementary methods;) a chapter covering an immense range of applicaons; and (6) a bibliography with classified index ntaining about 1100 references.

The book deserves the highest praise throughout r clearness, trustworthiness, comprehensiveness, nd interesting style. One might perhaps have shed to see the applications treated in greater tail, but when the number of references is realised aders will perhaps be inclined to agree with the thor that it may be better to leave the detailed eatment of applications to the several sciences to ich they belong. The author divides applicaons into two classes: (*a*) Those in which the enomenon under investigation or control is iously affected by the p_H of the solution and ich require the most accurate methods available. r these he recommends the use of the electrotric method. Obviously the difficulties to be met d corrections to be made increase greatly with accuracy required, and it would have been inesting to hear to what degree differentiation of ential has been hitherto usefully applied. (*b*) r those applications in which so high a degree of uracy is not required the author recommends the icator methods. The reviewer is inclined to ieve that when the millivoltmeter system of measurement is employed (which in the present book, as in most American publications, is ascribed to Hildebrand, but which was fully described two years before Hildebrand by the reviewer, in conjunction with Wood and Law, in its application to tan-liquors), the electrometric method has many advantages over the indicator method in cases where the total curve of neutralisation by acids and alkalis is important, and in which an accuracy of about one centivolt is sufficient. Thus, in the examination of soils one titration of the soil suspension with an acid and one with an alkali by the electrometric method will show not only the hydrion concentration of an extract of the given soil, but also the hydrion concentration which such an extract would show after known quantities of acid or alkali have been added to or have been formed in the soil.

The reviewer feels confident that, in spite of the large amount of work already done, there still remains a widening field of application for the determination of hydrion concentrations; and also that the present book will contribute materially to the popularisation and extension of this important branch of physico-chemical measurement and inquiry.

HENRY J. S. SAND.

THE PRINCIPLES OF THE PHASE THEORY. *By* DOUGLAS A. CLIBBENS. *Pp.* xx.+383. (*London: Macmillan and Co., Ltd.* 1920.) *Price* 25*s. net.*

There is in many quarters to-day an increasingly clear perception, based to some extent on war experience, of the definite bearing of physical chemistry on many technological problems, and the present volume may be regarded as a product of this view. The particular field with which Dr. Clibbens deals has been cultivated more especially by the Dutch school of physical chemists—Roozeboom, Schreinemakers, and others—and has received all too little attention in Britain. On this ground, as well as on its own merits, the appearance of an authoritative work dealing with the phase rule in the English language is to be heartily welcomed.

The principles of the phase theory make possible a rational survey of the influence of temperature and concentration on the equilibrium condition of a material system, and it is in the resulting unification of treatment that the value of the phase rule mainly consists. A remarkable feature of the development of this subject has been the graphical methods, such as the equilateral-triangle representation and the projections of the space diagrams, devised to facilitate the recording of the complex phenomena involved. In this connexion there is an interesting remark made by Mr. F. A. Freeth, who contributes an introduction and to whom the volume largely owes its inception, viz., that the graphical methods introduced for phase rule purposes have served to emphasise the vital principle that *every point* on a diagram—not merely those on the curves—has a definite meaning.

Within the limits which Dr. Clibbens has set himself the present volume furnishes a detailed and thorough treatment of the subject, compiled by one who is evidently at home in these matters. The argument is on non-mathematical lines, and the development can be followed by a beginner, but at the same time he must be prepared for much patient work if he aims at achieving a real mastery of the subject. The power to interpret a complex phase-rule diagram is not easily acquired, and, in view of the concentrated attention which even a few pages of the present volume demand, it is scarcely suitable for the undergraduate student as an introduction to the phase rule. For the advanced or research student the book can be

heartily recommended, and it is matter for congratulation that such a volume is now available for English readers.

The author purposely limits the scope of the work to the consideration of condensed systems, including only one liquid phase, and that the only phase of variable composition. His view, with which most physical chemists will agree, is that a true comprehension of the phase theory can best be attained by a thorough study of the condensed system. Further, it should be noted that the experimental illustrations of the theory which Dr. Clibbens discusses are taken solely from the field of salts and aqueous solutions, although naturally the theory developed is equally applicable to all condensed systems.

Somewhat less than half the book is devoted to the consideration of condensed binary and ternary systems, while the remainder is concerned mostly with quaternary and quinary systems. Naturally, the graphical representation plays an all-important *rôle*, and the volume is profusely illustrated with some two hundred diagrams. As regards the text, the reviewer has the feeling that there is occasionally too much repetition. On the other hand, mastery of the principles and methods of the phase rule can admittedly be achieved only by the most painstaking attention to details, and a little over-repetition is not a serious fault in this case.

James C. Philip.

The Carbohydrates and Alcohol. *By* Samuel Rideal *and Associates. Pp.* 219. *Industrial Chemistry Series. (London: Ballière, Tindall and Cox.* 1920.) *Price* 12*s.* 6*d. net.*

This volume is one of a series designed to give a comprehensive survey of the chemical industries. The series, of which nine or ten volumes have already been published, has been conceived on somewhat novel lines, one of the aims being to present to the advanced student the reality of the living industry without confusing his mind with details and figures, which may be obtained from more highly specialised text-books. In certain respects this aim is admirably achieved in the present volume, and the sections on cane and beet sugars, which occupy roughly 100 pages, or about half of the book, give a clear, succinct, and eminently readable account of the commercial production of sucrose. A short history of the development of sugar production from the earliest times, and an outline of the physiology of the sugar cane and of the agricultural methods adopted, add greatly to the value of these sections.

Of the rest of the volume the impression gained is that an attempt has been made to cover too much ground. The subject of patent stills is dealt with in 25 lines, and the use of alcohol as a fuel in 20 lines. Beer and brewing occupy 20 pages, and only nine are allotted to wine, including the recovery of tartar. Thirty pages are devoted to grain spirit, potable spirits, industrial alcohol and synthetic alcohol.

Within these limits the subject matter is well and clearly dealt with, and the authors have contrived to get a large amount of information into a small compass, but the value of the book would have been greatly enhanced by a fuller treatment of fermentation and distillation. The authors have no doubt been restricted by limitations of space, but it would perhaps have been more satisfactory if the fermentation industries had been dealt with in a separate volume. It might then have been possible to include a few more diagrams and illustrations of plant, which in the sections on fermentation are conspicuous by their absence.

The production of alcohol by the hydrolysis of wood and subsequent fermentation of the sugars formed is included in the section on synthetic alcohol. This arrangement seems to call for revision, as the term "synthetic" can strictly be applied only to alcohol produced from acetylene or ethylene, or by methods other than fermentation.

The book contains so many excellent features and is written in such a clear and attractive style that it is to be hoped that in future editions the treatment of the subject matter will be more evenly balanced, even if this involves considerable expansion.

G. W. Monier-Williams.

First Report on Colloid Chemistry.—By arrangement with the Department of Scientific and Industrial Research, the First Report of the British Association on Colloid Chemistry and its Industrial Applications is to be reprinted and issued for sale by H.M. Stationery Office. Copies (price 2s. 6d., or by post 2s. 7½d.) may be obtained through any bookseller, or from H.M. Stationery Office in London or its branches in Manchester, Cardiff, and Edinburgh. A small stock is also held for sale at Messrs. Hortons, Harrison Street, Johannesburg, South Africa, and by the Government Printer, Wellington, New Zealand. The Report is no longer to be obtained from the offices of the British Association.

THE DRAFT HOME OFFICE REGULATIONS FOR CHEMICAL WORKS.

(From the Association of British Chemical Manufacturers.)

The provision of hygienic conditions for labour and of protection from danger for workers is now recognised as being absolutely essential in every industry, and especially is this so in the chemical industry where the work involved in certain manufactures is of a dangerous and unhealthy character. The draft Regulations for Chemical Works recently issued by the Home Office have set a very high standard for the conditions of employment to be maintained in chemical factories. This is very desirable, but it is felt by a large section of the industry that some of the proposed demands are of an extravagant and impracticable nature. In the larger and more modern works the provisions made for the health and general welfare of the employees are in most cases excellent, but the enforcement of the proposed regulations will, even in these instances, involve additional expenditure. It is therefore to be regretted that the new regulations are being introduced at a time when the financial position of the industry cannot bear the additional expense which will be incurred in carrying them out. This is particularly true of the smaller chemical works engaged in branches of the industry which are at present in their infancy, such as fine chemicals, intermediates and dyes, and it is generally recognised that at the present time it is not in the interests of the industry at large to place upon those works additional burdens unless they are absolutely essential to the welfare of the worker.

Part I of the Regulations applies to all chemical works and includes provisions for mess and washing accommodation, ambulance and rescue equipment. These provisions would doubtless conduce to the well-being of the worker, but they are framed on too lavish a scale. The demands made for the provision and maintenance of suitable protective clothing (Clauses 11 and 12) are of an extravagant nature unless they are restricted in their application to those persons *constantly* engaged in work involving *continuous* exposure to wet or dust or to substances of a corrosive or poisonous character. With regard to the supply of adequate bath accommodation (Clause 15), the employer has received very little encouragement in this respect in the past owing to the small advantage taken by the worker of the bathing facilities placed at his disposal. It is therefore only natural that the smaller manufacturer should feel reluctant to expend money on the installation of baths when it is probable that little use will be made of them by the employee. As regards Clause 21, which provides sitting accommodation for employees "whose work is done standing," it is generally agreed that such provision is impracticable and open to abuse. It is further considered that greater detail is required in the wording of the regulations in order to enable them to be carried out effectively. In the provision relating to the use of life-belts and rescue apparatus, for example, it is essential that the size of the manhole should be specified, and it is considered that the provision of an efficient exhaust-draught in lime-slaking (Clause 3 (b)) should only hold good when the quantity of material used in the process exceeds a specified limit. Clause 2, which refers to the provision of adequate measures to prevent steam from obscuring platforms, passages, etc., is obviously impracticable, unless it applies only when the surroundings are *continuously* obscured by the evolution of steam.

In Part II of the Regulations the provisions apply particularly to those works in which caustic pots are used and to places where chlorate, bleaching powder, dyes, and intermediates are manufactured. In these cases the regulations relating to washing facilities are naturally more stringent and involve the supply of baths, nail brushes, soap, clean towels, the provision of which, although desirable, is so readily abused in practice. It is, of course, generally recognised that all these precautions are absolutely essential in the manufacture of such irritants as dinitrochlorobenzene and TNT, and it is doubtless the experience gained in this respect during the war which has led to the inclusion of these provisions in the new regulations. It is to be feared, however, that according to the schedule of processes included under Part II, it will be necessary to satisfy these provisions in many cases where they are not absolutely necessary. The provision for the repair and cleaning of gloves (Clause 31 (a)) is regarded as impracticable, and it is considered that the washing facilities provided for in Clause 33 should be supplied only for those workers who are *continuously* engaged in the various processes mentioned.

It is generally felt in the industry that had the collaboration of such a body as the Association of British Chemical Manufacturers been secured in the compilation of the regulations they would have been found more generally acceptable to all sections of the industry.

THE BRITISH GAS MANTLE INDUSTRY.

Among the industries that are seeking State assistance through the projected Government Bill relating to "key" industries are the gas-mantle and subsidiary industries. On behalf of these a statement has been presented to the Board of Trade by the Incandescent Mantle Manufacturers' Association, the main points of which are summarised below:—

The Gas Mantle Industry bases its claim to be regarded as a "key" industry upon the following considerations:—I. Both in time of peace and in time of war incandescent gas lighting is necessary for the adequate illumination of docks, railways, factories, etc. II. It is estimated that 32 million tons more coal would be required yearly to produce the same illumination if flat-flame burners were used instead of gas mantles. III. The "stripping" of coal gas has been found necessary to ensure adequate supplies of benzol, toluol, and other hydrocarbons for the manufacture of dyes, drugs, and explosives; such "stripped" gas can only be used as an illuminant in conjunction with the gas mantle.

The value of the industry from the standpoints of efficient illumination and coal conservation was recognised by Lord Balfour of Burleigh's Committee on Commercial and Industrial Policy, and recent legislation authorising the sale of gas on a calorific, instead of an illuminating, basis has further emphasised the importance of the gas mantle. In Germany the essential nature of this industry, including the raw materials therefor, has been recognised by granting special allocations of coal at the lowest price and supplies of gas which are otherwise restricted.

Before the war the rare-earth chemicals and the gas-mantle industry were mainly under foreign domination. The total output of Indian monazite sand went to Germany, and British mantle-makers had to purchase thorium nitrate abroad at a price

fixed by the Thorium Convention, a combine of German and Austrian manufacturers which was itself controlled by the chief German maker of gas mantles. Further, foreign mantles were sold in this country at prices 2—35 per cent. below English factory costs, and 23—70 per cent. below the selling prices in the countries of origin. In 1913 foreign importations amounted to between 45 and 50 million finished mantles and over 11 million partly finished (about 70 per cent. of our entire consumption), and the latter were marketed in such a way as to evade the payment of British income tax by the English branch of the German combine, the Auer Gesellschaft. In the same year the English production was 22 million mantles, of which 10 million was made by a company associated with the German combine.

In consequence of this foreign domination the home industry became very precarious; nearly all the factories were running at a loss, wages were low, and employment uncertain and unsatisfactory. Hence at the outbreak of war there was insufficient plant to meet the country's requirements, supplies of thorium nitrate were cut off, and there was a shortage of clay rings and other materials required by the industry. To overcome these difficulties the Indian monazite deposits were placed under British control, and five home manufacturers took up the preparation of thorium nitrate, although until the factories were ready the nitrate had to be purchased abroad at arbitrary prices which showed large profits to foreign suppliers. These factories can now produce all the gas mantles the country requires; and during the war they supplied the cerium fluoride and cerium oxalate needed for searchlights and tracer bullets. Prior to the war all the mantle rings required by the home industry were either imported from Germany or supplied by a German-owned company with branch works in this country. These works were purchased by a group of the chief British mantle-makers and so extended that they are now able to meet the country's requirements, although not yet in a position to produce the full range of designs which were offered by the Germans. Ramie yarn, which was also derived from Germany before the war, can now be supplied by British spinning plants in sufficient quantity to meet all requirements.

Owing to the extensions made to buildings and plant (at war prices), and to the establishment of three or four new factories, the output capacity of the home industry is now over 130 million mantles per annum, which is sufficient to leave a considerable surplus for exportation. The following data show the position of the British industry in 1913 and on October 30, 1920:—

	1913.	1919-20.
Output of mantles	32,000,000	82,322,000
Capital employed	£440,670	£1,525,710*
Workers employed	1843	3783

* Exclusive of £350,000 invested in the thorium nitrate and other subsidiary industries.

The present annual consumption of gas mantles is valued at £1,750,000; £400,000 is paid in direct wages, and at least an equal sum as indirect wages to convert the imported raw materials into the products used by the industry, labour and wages entering into the cost of the finished article to a degree unusual in other industries. The raw materials used by the gas-mantle manufacturer include thorium nitrate and other chemicals, cotton, ramie, artificial silk, asbestos yarns, clay rings, and cardboard boxes. At the present time there is grave stagnation in the above trades, which is mainly due to the increasing importation of foreign mantles (over 10 million in 1920), and the prospect of further competition at prices below British manufacturing costs. The low prices of foreign mantles are the result of :—(a) Attempts by foreign makers to recapture their former markets at any cost; (b) the low rate of foreign exchanges; (c) longer working hours in foreign factories (60 hours or more per week compared with 48 in this country) and the lower standard of living of the worker; (d) large pre-war stocks of certain raw materials held by German manufacturers. The British consumer is not obtaining the full benefit of the lower prices, as the intermediate profit is mainly retained by the importers and dealers. The Labour representatives on the Joint Industrial Council for the industry proposed a resolution, which was passed unanimously, deploring the increasing importation of foreign mantles, and urging the Government to take steps to counteract the effects due to foreign rates of exchange. At the present time some of the British factories are closed down, and the rest are working short time; manufacturers are carrying large stocks at a season when demand normally exceeds the rate of production; employment in the industry is declining, and generally the situation is so serious that immediate action is imperative. In conclusion, it is submitted that the manufacture of thorium and rare-earth salts, incandescent mantles, and clay rings be recognised and assisted as "key" industries; that legislation be introduced forthwith to protect the British worker against unemployment resulting from foreign competition; and that the British manufacturers who have responded to appeals to lay the foundations of a self-supporting industry be assured a market free from unfair competition.

THEORY AND PRACTICE IN CHEMICAL INDUSTRY,

With special reference to Physical Chemistry.*

E. B. R. PRIDEAUX.

Although the principal difficulties under which chemical industry is labouring in this country are political and social, and therefore beyond the control of industrial organisers and chemists, there is a minor handicap, the neglect of theory, which can be overcome by the efforts of individual workers. The most successful practical men are, unconsciously, often great theorisers, but in most cases they would increase their efficiency by studying the theories which bear upon their processes—if only to distinguish between practicable and impracticable inventions, between theories which lead nowhere and others which embody useful working hypotheses. In building up a healthy industry able to withstand severe foreign competition, theory and applications must be closely allied. For new points of view and working hypotheses, the industry is dependent, as it always has been, upon the work of private investigators, and especially upon the research work done in universities and technical colleges. In his presidential address to this Society in 1904, Sir W. Ramsay related how a scientific friend once pointed out to him that most of the changes which had been introduced in industries had originated in universities. Why? Because the investigator is unfettered. If a man sets out to improve an existing process he will very likely succeed, but he will not revolutionise a manufacture.

Not the least useful part of the expenditure of the Department of Scientific and Industrial Research has been that applied to maintenance grants in aid of student research workers in pure science. The business community would do well to follow the splendid example of private munificence which has been set in Nottingham and provide donations, to be used more especially for increase of staff and

* Paper read before the Nottingham Section on Dec. 15, 1920.

quipment, in order to give the research students of Nottingham the best possible chances of dis-inguishing themselves, and of becoming versed in, and putting to the test, a wide range of theories. Both in applied and in pure science theories are the "imponderables" which enable us to control ponderable phenomena.

Few will doubt the efficacy and value of the "common stock" chemistry, in which the essential has been so thoroughly sifted from the unessential, and the ways made so plain that a good grasp sufficient for application can be obtained in a three years' course. Much of this was, however, in its inception "physical chemistry," and most strange to the orthodox chemists of the early 19th century. Now a new science, or rather many branches commonly summed up as "physical chemistry," have grown on the "common stock," and the student, sometimes also the teacher, stands bewildered. How much of all this is to be mastered, how much left untouched? It seems probable that in these branches the great advances of the future will lie, as they are applied one after another to the hitherto unsolved, or only empirically solved, problems. It is in these uncharted regions that gold is to be picked up, not necessarily for private profit, but for the advantage of the whole nation and human-ity; and the more uncharted the country, the more necessary is the guidance of theories, even if these are only provisional in character and if each leads only a short part of the way.

Hence any real success in applied science is only gained after a liberal training on the theoretical side. The successful inventor or improver in chemi-cal industry must be able to assimilate the results of research in pure science, and he must be quick to see their bearings and able to work out their applications. The trouble is that it is difficult or impossible to discern the bearing of a theory on technical processes until it has been read and under-stood. The original papers are perhaps written in difficult language, an interpreter is required, and he is usually a teacher who introduces it into a text-book. But long before this the first fruits may have been seized by some industrial chemists who have been adequately trained to master and apply theories.

The tendency in works' laboratories is to tabulate the results of pure science and to work out their applications, and the newly-formed Research Associations are in many cases working along these lines.

This is perhaps a partial answer to the question asked by many entrants into the chemical profes-sion: Of what use is physical chemistry to me, or what opportunity shall I have of practising prin-ciples which will perhaps require an inordinate amount of time and energy? If the young man of good will and energy will enter these studies, he will surely find in them sufficient interest to carry him on, and eventually they will afford him a greater choice of posts in the profession. Although he may consider himself rushed during his univer-sity career, actually he has then more time and available energy than afterwards when he is in full work. Many of the most useful branches of physical chemistry can be applied quite effectively to a first approximation with the aid of sound elementary mathematics. Indeed, it is not so much the mathe-matics involved as the abstract ideas which present the difficulty. For example, those of osmotic pressure, concentration action, solubility product, electrolytic solution pressure, ions, free and total energy, the EMF of chemical reactions, velocity constants, and thermochemistry all require careful consideration from several points of view before they can be assimilated. Some can grasp them at once in the abstract form, but the usual road to, and test of, comprehension is through the working of numerical examples. By whatever means, the essential principles ought certainly to be acquired in student days as so many foundations upon which complete buildings may later be erected.

It will be found that thus an added power and a deeper insight into technical problems are obtained. Even when processes have reached a high degree of perfection and are run according to rule, so that apparently they hardly need the supervision of a professional chemist, it will be safer to employ one who has gained this depth of insight. However stereotyped a process may become, it has to be grasped by each new generation, and a study of the theories is the surest method. Even long-estab-lished processes occasionally break down, and few chemical reactions are as perfectly controlled as a steam engine.

The great generalisations of physical chemistry are required for the solution of most problems as soon as the reactions are carried out on a large scale. For example, the behaviour with regard to changes of pressure, temperature, and concentra-tion of systems consisting of a gas, one or two liquids, one or more solids is described and put on a quantitative basis by the phase rule and other deductions from thermodynamics. There are some works chemists who consider the phase rule as important a tool as the "slide rule." These theories, with the aid of applied physics, dominate the operations of distillation, crystallisation, ex-traction and filtration, just as applied physics dominates those of heat exchange, flow of fluids, grinding and mixing; and the mere chemical side of physical chemistry dominates those operations in which chemical equilibrium, velocity of reaction, and electro-chemical processes are most important. To take one example, the laws relating to the crystallisation of mixed liquids are of the first im-portance in ferrous and non-ferrous metallurgy. A study of the conditions of formation of eutectics, of maximum freezing-point, compounds and solid solu-tions of various types, are equally important in organic chemistry. Thus, in the manufacture of margarine the freezing-point diagrams of the fats stearin, palm oil, etc. have been studied in order to obtain a mixture of from three to six fats which melts at about 25° C.

In the examination of technical products physico-chemical or physical tests have largely replaced chemical analysis. Thus, in ferrous metallurgy cool-ing curves, heat treatment, and microscopic analysis give the most important information. In other branches of industrial analysis it is often a question of determining the amounts of two or more *known* constituents of a mixture. Two physical constants, such as the density and initial boiling-point, may be sufficient to characterise the mixture. Numerous examples may be found of these methods in recent issues of the *Journal*. Sometimes a single constant such as the optical rotation is sufficient. The use of the refractometer, for example, is becoming very prominent. A single drop of liquid suffices to give a number which distinguishes oils from one another or which reveals presence of admixtures. A useful example of the combined use of refractive index and other constants in butter analysis is to be found in the work of Mr. H. D. Richmond, who also informed the author that the refractometer is largely used in the jam industry to determine the degree of evaporation of the syrup.

To illustrate the manifold applications of physical chemistry it is not necessary to go beyond the record of this Section. Reference need only be made to the work of Sand, Wood and Law, who have adapted the hydrogen electrode to determine the acidity of dark-coloured tan liquors; to that of Procter, who has investigated the effect of acids and alkalis upon gelatin and leather material from the physico-chemical point of view; to that of Archbutt on the skin effect in lubricants; and to that of Wilkie on the conditions of reduction of

arsenic compounds at a lead kathode, which are doubtless capable of interpretation in terms of reduction potentials and velocities of successive reactions. The author believes that the industries of the East Midlands are waiting for control chemists able to interpret the wealth of research which has long been available. Can anyone suppose that the last word has been said in the exploitation of gypsum deposits? or that the chemical utilisation of our splendid coal deposits is carried on as largely as it might be in the district? or that great economies in labour and material, as well as improvements in the products, are not possible in our textile industries so soon as these are fully staffed with chemists?

One of the best examples of the value of working hypotheses is afforded by colloid chemistry. The chemical formulæ of soaps are well established, reversible chemical equilibria are present, and a regular gradation is found through acids and salts, such as acetates and propionates, which behave as regular electrolytes, up to oleates which exhibit truly colloidal phenomena. The properties of soap solutions cannot be interpreted in terms of the ions of sodium and of free acid radicle, more or less hydrolysed, giving free alkali and uncombined acid, which is more or less in the colloidal state. The question has now been attacked by the methods of conductivity, osmotic pressure, viscosity, surface tension, microscopy, ultramicroscopy, and ultrafiltration. The results as summarised in the Reports on Colloid Chemistry are of outstanding importance to all makers and users of soap. The work of the founders of colloid chemistry, as well as that done on soap by Harkins, Hillyer, Spring, Pickering, Donnan, McBain, and many others, has now resulted in descriptive theories which will enable anyone trained in the principles to take up technical problems with a fair chance of success. Immediate practical results are numerous, such as the recommendation to use sodium oleate in cold solutions on account of its solubility, and sodium stearate in hot solutions on account of the persistence of its colloidal nature. In order to account for the relatively high electrical conductivity, relatively low alkalinity (low hydrolysis), McBain has postulated the existence of "ionic micelles"—aggregates of fatty acid ions highly charged as compared with usual colloidal matter, and not visible by the ultramicroscope. These particles functioning as protective colloids account for two of the principal uses to which soaps are put. As a small quantity of gelatin or other colloid prevents the coagulation of red gold sols by salts, so the soap colloid prevents the coagulation of dirt particles, or rather assists their passage into the dispersed state in which they are easily washed away.

The production of stable aqueous emulsions by the addition of small quantities of soap is explained in a similar way, but is still more precisely described by Donnan and his co-workers as due to the lowering of the tension at an oil-water interface by the addition of small quantities of soap. Here the entirely theoretical work of Willard Gibbs pointed out the way which has led to such eminently practical results.

* * *

In connexion with the above paper, Mr. H. Droop Richmond communicated the following:—Dairying is one of the oldest industries; it is not usually regarded as a chemical industry, nor as affording much scope for the application of physical chemistry, but when it is considered that the raw material—milk—is an emulsion of fat, in the liquid or solid state, in an amphoteric colloidal solution of the soluble salts of a complex, fairly strong insoluble acid, no further argument is required to show that physico-chemical problems of the highest order occur in dairying. As an old industry, it is apparent that very many of the problems have been worked out by empirical methods, but they are far from having been elucidated completely. We do not know for certain the state of the fat globules in milk, though I think that my work, undertaken in conjunction with my brother, has shown that they are liquid above the melting-point of fat, and solidify very slowly on cooling; and I think that there is little doubt that they are not surrounded by any membrane other than a colloidal layer condensed by surface energy. We have comparatively little information as to the variation of this layer with changes of temperature, especially when the temperature is raised to such a degree that irreversible changes take place in the serum, yet this fact has importance in dairying. The laws of the rate of motion of these globules when submitted to the force of gravity, centrifugal force, and irregular impulses are only partially known, though of the highest importance in cream separation and butter churning. The motion of single globules is comparatively simple, but in milk the globules vary greatly in size and the practical importance of the laws of their motion becomes greater as their complexity increases, owing to close packing and also to variations of temperature; and until their laws are fully elucidated the scientific design of separators and churns is impossible.

The amphoteric nature of milk is due to the presence of salts of polybasic acids, the hydrions of which have widely differing concentrations; that is to say, hydrion concentration in milk does not vary with acidity. Cheese-making, which depends primarily on enzymic action, which in its turn is influenced by the hydrion concentration, has been controlled largely by acidity determinations in the main satisfactorily, but there is no doubt that a more scientific application of physical chemistry would result in an important improvement. In the manufacture of condensed milk, the hydrion concentration is increased and, unless the proportion of buffer salts is increased, it becomes too great to enable the milk to withstand the subsequent operation of sterilisation without the separation of insoluble acid salts; and this raises an interesting physico-chemical problem. The problem of escape of dissolved gases from a colloidal solution, attended by great foaming, has considerable importance. In the manufacture of casein and milk sugar there is on the one hand the problem of the separation and drying of a colloidal precipitate, and on the other the crystallisation of the sugar from a solution containing crystallisable salts.

CULTIVATION OF THE AFRICAN OIL PALM.

With special reference to the East Indies.

An interesting article has appeared under the above title in the *Bulletin of the Imperial Institute* (1920, 18, No. 2, 209—252). Hitherto nearly all the palm oil and palm kernels of commerce has been obtained from wild trees in West Africa. The palm oil is prepared by the natives mainly by primitive methods which frequently result in the production of a low grade of oil, and the kernels are usually extracted by cracking the nuts by hand, thus entailing a great waste of labour. Owing to the great demand for fats of all kinds at the present time, much attention has recently been devoted to the cultivation of the palm in plantations and the preparation of the palm oil and kernels under modern factory conditions. The article under review has therefore been written with the primary object of supplying information which will be of service to planters or companies who may contem-

plate the establishment of oil-palm plantations. It deals fully with the distribution of the oil palm and the present position of its cultivation in various countries, describes the palm and its chief varieties, the climatic and soil conditions best suited to its growth, and the methods of cultivation and harvesting. The question of yields is discussed, and estimates are given of the probable financial returns obtainable from a plantation. The following points may be mentioned as of especial interest.

The importance of the oil-palm industry in West Africa may be gauged by the fact that the total annual exports now amount to about 130,000 tons of palm oil and 400,000 tons of palm kernels. The greatest output is in Nigeria, and in 1919 more than 100,000 tons of palm oil and 216,913 tons of kernels were exported from that country. Palm-kernel oil is not produced for export in any part of West Africa except Nigeria, whence 3356 tons was shipped in 1919.

Comparatively little attention has been given hitherto to the cultivation of the oil palm in plantations in West Africa, but plantations have been made in the Cameroons and at Gazi in the Belgian Congo, whilst in San Thomé the palm is commonly planted as shade for cocoa. The production from the wild trees could be greatly increased by thinning out the trees and clearing the undergrowth round them.

The cultivation of the palm as a regular plantation industry has only been carried on up to the present on the east coast of Sumatra, where in 1919 the area devoted to this crop amounted to 12,800 acres, of which 6900 acres was in bearing. The palm has been planted successfully on a smaller scale in the Malay Peninsula, and several large areas have recently been taken up in the Federated Malay States for its cultivation on a commercial scale. In Sumatra the trees usually begin to fruit at the end of the fifth year, but in some cases they bear a crop in the fourth year.

Little is known with regard to the yield of fruits from the different varieties of oil palm, and therefore it is not easy to recommend any particular variety for cultivation. Assuming that the yield is satisfactory, however, it is desirable that a thin-shelled variety should be selected which gives a high yield of oil from the pulp and a fair yield of kernels. If the nuts are to be shelled by hand, the thickness of the shell is very important, but is of less consequence if nut-cracking machinery is employed.

The oil palms on the east coast of Sumatra are regarded as probably all derived from one variety, but it is not yet decided with which African variety this kind is identical. The advantage of cultivation is shown by the fact that in Sumatra, as also in Malaya, the tree has proved remarkably precocious, yielding large quantities of fruit at a much earlier age than in West Africa.

Detailed information on the yields given by trees of various ages in the Sumatra plantations has been given by Dr. A. A. L. Rutgers in *Mededeeling van der Algemeene Vereeniging van Rubberplanters ter Oostkust van Sumatra* (Algemeen Serie, No. 6, 1919, and No. 8, 1920), and the tabular statements therein have been reproduced in a somewhat modified form in the article under review. These tables give statistics of the gross yield of bunches and of fruits, the percentage of pulp, nuts and kernels in the fruits, and the percentage oil content of the pulp and kernels. From these particulars the following conclusions have been drawn.

The estimated normal annual yield of a plantation in lb. per tree is given below for trees of different ages:—

—	Number of bunches.	Weight per bunch.	Total weight of bunches.	Total weight of fruits.
5th to 10th year ..	12	13.2	158	53
11th to 30th year ..	10	33	330	165
31st to 50th year ..	3	44	132	66

The oil palms now generally grown on the east coast of Sumatra give a high yield of pulp (62 per cent. of the weight of the fruit) and a low yield of kernels (8 per cent.). The fresh pulp of the fruits contains about 55 per cent. of oil and the kernels contain about 50 per cent. These yields are regarded as very satisfactory.

In establishing an oil-palm planting industry on modern lines—that is, with the use of machinery for preparing the palm oil and cracking the nuts—it is estimated that it would be necessary for profitable working to plant an area sufficient to produce 6000 tons of fruit per annum. From the fifth to the tenth year the average annual yield of fruits per tree is 53 lb., and from an acre bearing 64 trees (*i.e.*, planted 26 ft.×26 ft.) the total yield would thus be about 1½ tons; the actual area required to produce 6000 tons of fruit would therefore be about 4000 acres.

The theoretical yields of fruits and oil from an acre of oil palms planted with 64 trees are given as follows:—

	Number of bunches.	Total weight of bunches. Tons.	Total weight of fruits. Tons.	Total weight of pulp. Tons.	Total palm oil. Tons.	Total weight of kernels. Tons.	Total palm kernel oil. Tons.
5th to 10th year	768	4·51	1·51	0·906	0·498	0.121	0·060
11th to 30th year	640	9·44	4·72	2.826	1·554	0·377	0·189
31st to 50th year	192	3·77	1·89	1·134	0·624	0·151	0·075

In calculating the profits obtainable from an oil-palm plantation, it is necessary to take into consideration not the theoretical yields quoted above, but the practical yields. With modern machinery it should be possible to extract 80 per cent. of the oil contained in the pulp, and the whole of that in the kernels. The practical yield, therefore, may be estimated as follows:—

	Palm Oil.		Palm Kernels.	
	Per acre. Tons.	Per 5000 acres. Tons.	Per acre. Tons.	Per 5000 acres. Tons.
5th to 10th year ..	0·398	1990	0·121	600
11th to 30th year ..	1·243	6220	0·377	1880
31st to 50th year ..	0·499	2500	0·151	750

On the basis of these results, together with considerations of the cost of machinery, land, labour, and upkeep, and the market value of the produce, it is shown that oil-palm plantations are likely to prove more profitable than coconut estates.

SOCIETY OF CHEMICAL INDUSTRY.

NEWS FROM THE SECTIONS.

GLASGOW.

At an informal meeting held on January 12, with Mr. J. H. Young in the chair, short papers were read on "Gas Warfare" by Prof. F. J. Wilson, and on "The Use of Magnesium Oxychloride Cements in Ships" by Dr. J. G. Robinson. The first paper described the methods of gas warfare used by the enemy, the nature of the substances employed and their physiological action. Dr. Robinson outlined the development of the manufacture of magnesium oxychloride cements, described their use for ornamentation and mural

decoration, and concluded with an account of the application of composition flooring as a substitute for wood decking on board ship. When used in conjunction with hard-wood sawdust, these cements make an ideal decking, as they are very resistant to heavy wear and tear, are fire- and vermin-proof, and are better insulators than wood. They can be laid more thinly and more quickly, and are cheaper than wooden decks. The danger of corrosion and the means of preventing it were described, and the difficulties were shown to be due mainly to the presence of excess of water, which vitally affects the expansion and also the tensile strength.

EDINBURGH AND EAST OF SCOTLAND.

An informal meeting was held in the Hall of the Pharmaceutical Society, Edinburgh, on January 18, Mr. J. Rutherford Hill presiding. Prof. G. Barger presented a communication on the Micro-Dumas Method of Determining Nitrogen, the apparatus being demonstrated by Mr. Harington. Mr. B. D. W. Luff showed a device to avoid overstepping the end-point of a titration, and Mr. M. T. Hay described a safety device for Carius tubes. Mr. W. T. H. Williamson gave a short account of the present position of the theory of soil acidity, and described some recent methods of testing acid soils.

NEWCASTLE.

At a meeting held in the Chemical Lecture Theatre of Armstrong College on January 26, a demonstration was given of the froth flotation process for the washing of coal. Mr. A. Bury, of Skinningrove, read the introductory paper and Mr. Bicknell carried out the subsequent demonstration.

Mr. Bury briefly reviewed the development of the coal-washing industry and pointed out that all methods previously used had depended upon the difference in specific gravity between the coal and the associated waste. Such methods failed in treating fine material, and the need had long been felt for a complementary or supplementary method capable of dealing with these refractory fines. A successful method had been devised by the Minerals Separation, Ltd., which was now being worked in Wales on a commercial scale.

A special laboratory has been established at Skinningrove with machinery and apparatus capable of dealing with samples from 400 gm. up to 1 cwt., which is at the disposal of all interested in the subject in the Cleveland, Durham and Northumberland districts. During a year's work at this laboratory many coals have been tested and the process has proved of the widest applicability. A list of excellent results obtained on raw coal, washery refuse, pit refuse, dump material, picking waste, etc., was given. Most coals consist of a mixture of pure coal of low inherent ash, bone coal containing high inherent ash, and shale containing varying amounts of bituminous matter. It is possible by the proper application of the flotation process to separate these constituents one from the other and thus obtain:—(*a*) A clean product of low ash content whch gives an excellent coke, (*b*) a bony coal to be used for fuel purposes, and (*c*) a shale free from coal.

In making the demonstration it was shown that when water is agitated with small quantities of certain reagents, numerous very fine air bubbles are formed. When the coal is added to such a mixture the air bubbles attach themselves to the coal particles, and when the pulp is brought to rest the bubbles rise to the surface carrying the coal particles with them, forming a froth in which the solid particles are supported; the shale particles remain suspended in the water or settle at the bottom of the containing vessel. Mr. Bicknell demonstrated the efficiency and simplicity of the process, obtaining both clean coal and clean shale residues.

LIVERPOOL.

On January 24, a meeting of this Section was held at Midland Adelphi Hotel, Liverpool. Dr. E. F. Armstrong presided, and Dr. Stephen Miall read a paper on "Diseases of Occupation."

Dr. Miall stated that, broadly speaking, constant exposure to any chemical compound was likely to be injurious to health, particularly when the compound gave rise to dust, fumes, or gas. The best general preventive was undoubtedly an abundant supply of fresh air, and the old-fashioned, dilapidated works had compensatory advantages over modern factories inasmuch as broken windows let in air and the worker was given a variety of occupations. Poisoning by gases from gas and internal combustion engines was increasing, but in nearly all cases was due to ignorance or carelessness on the part of the worker. After describing some measures which had led to the practical extinction of phosphorus poisoning, Dr. Miall referred to the toxicity of turpentine as the cause of the poisonous effects due to inhaling fresh paint, and then dealt with the characteristics of metallic poisoning, notably by lead and lead compounds. The diminution of cases in the white lead industry was very remarkable, and was the outcome of 20 or 25 years' study and the steps taken by the Home Office. The prohibition of the use of lead in paints would not adequately solve the problem; the real remedy was fresh air. Painters should rub down old paint with sandpaper moistened with mineral oil. Lead pigments should always be supplied ground in oil or other medium, and adequate ventilation would do the rest. It was difficult to induce such organisations as the International Labour Office to regard the subject of occupational diseases from the modern medical standpoint, so obsessed was the public mind with the bad conditions which prevailed some twenty-five years ago, but which had since been remedied. The International Labour Office may do much good, but it will accomplish nothing in the sphere of industrial hygiene without the co-operation of those primarily affected.

BRISTOL AND SOUTH WALES.

A meeting of this Section was held on February 3, at Bristol. Mr. E. Walls presided, and Mr. D. T. H. Beaton read a paper on "The Brewing Industry," in which he traced the development of the art of brewing from the earliest times to the present day. It was stated that the origination of the art was ascribed to Isis in 1960 B.C., and that Herodotus had mentioned the production of beer from barley in 450 B.C. The annual production of beer was now about 36 million gallons, and the industry contributed £120,000,000 directly to the Exchequer, or 15 per cent. of the total national revenue.

The chairman announced that the annual meeting of the Section would be held on March 17, and that he would give an address on "Chemical Industry in Bristol."

MANCHESTER.

The fifth meeting of the session was held at the Textile Institute, Manchester, on February 4, Mr. John Allan presiding. A paper on "The Utilisation of Subsidiary Alkaloids," by Prof. F. L. Pyman, was read, in the author's absence, by the Hon. Sec., Mr. L. Guy Radcliffe.

In the paper Prof. Pyman briefly outlined the general process for the isolation of alkaloids. Consideration was given to the stereochemical differences existing among certain alkaloids and special

reference was made to atropine and the lævo form of hyoscyamine, an explanation being given of the transformation of the latter into the former. Reference was also made to pilocarpine and its relationship to iso-pilocarpine, and details were given of the chemical methods used for the methylation of the hydroxyl group and of the amido group, as well as methods of hydration in the case of ergotinine.

A considerable portion of the paper was devoted to the esterification of ecgonine obtained from the erythroxylon coca bean, and it was shown how the lesser valuable alkaloids could be easily and technically converted into the valuable cocaine. Reference was also made to the opium alkaloids, and especially to the utilisation of narcotine and papaverine. The optically active varieties of the styptic adrenaline, and the constituents of the *Hydrastis Canadensis*, better known as the Golden Seal, were described, and special emphasis was laid upon the value of the main substance hydrastine as compared with berberine, the latter being of little or no medicinal interest.

AMERICA.

The Perkin Medal for 1921 was presented to Dr. Willis R. Whitney at a meeting held at the Chemists' Club, New York, on January 14, Mr. Sumner R. Church, chairman of the Section, presiding. Dr. C. F. Chandler, senior past-president of the Society in America, in making the presentation, outlined Dr. Whitney's career, alluding more particularly to his work as Director of the Research Laboratory of the General Electric Company at Schenectady, N.Y., a post he has held since 1900.

In electric lighting the first radical improvement in the carbon incandescent filament was due to Dr. Whitney's personal work. The "metallised" filament, or "Gem" lamp, which he developed, gave 25 per cent. more light for the same wattage than the standard carbon-filament lamp. Millions of these new lamps were sold in a single year. A little later the laboratory solved the problem of mechanically working tungsten, and showed how to make the drawn wire which has given the tungsten lamp its universal application. The latest achievement of the laboratory in incandescent lighting is the gas-filled, or half-watt, lamp, which in its larger sizes has twice the efficiency of the vacuum lamp, and nearly equals the most efficient arcs. In arc lighting the magnetic electrode has been developed, and with it the most successful arc lamp of to-day. The laboratory has produced many new insulating materials and alloys, new processes, like "Calorising," for giving metals protective coatings; new articles of manufacture like "sheath wire"; new materials like "water japan" and "Genelite"; new electric furnace products like boron carbide, useful as a flux in casting copper, and titanium carbide for arc-lamp electrodes; new laboratory apparatus, such as the Arsem vacuum furnace, the tungsten tube furnace, the Langmuir condensation vacuum pump, the Coolidge X-ray tube, etc. Dr. Whitney was president of the American Chemical Society in 1910, and president of the American Electrochemical Society in 1911. He was awarded the Willard Gibbs Medal in 1916 and the Chandler Medal in 1920.

Dr. W. R. Whitney then acknowledged the honour which had been conferred upon him and gave an address on "The Biggest Things in Chemistry," which contained, among other things, the following dicta:—

In America patents are granted only to individuals, not to companies or laboratories, although the discoveries upon which they are based are often the result of corporate work. In this instance the award is to be regarded as belonging not to the recipient but to the research laboratory which he directs. Perkin's life contained all the data needed to analyse scientific research, and illustrates the fact that the great advances have usually been made by men trained in their particular line of investigation and working just beyond the boundaries of the known. Perkin's apprenticeship under Hofmann so imbued him with the spirit of scientific research that after years of commercial success he returned to it and enjoyed it for the rest of his life. The essentials for success appear to be the teacher of heuristic instinct, the laboratory, and the school training. It is incorrect to say that Perkins, Faradays, and Pasteurs are born, not made, for the process is entirely standardised. American schools have been working on the wrong lines, and instead of turning out men well trained in research they have been consuming energy in bringing large numbers of men only part of the way.

No two chemists would agree at first as to what constitute the most important things in chemistry, but on reflection many would admit that the biggest things are summed up in the word "possibilities." Chemistry has grown and survived because all its precepts and principles can be retested at any time and anywhere. It is a young science, but its rate of advance is almost incredibly rapid, and one feels that no one has ever had such possibilities open to him as the present-day student of chemistry. The process Perkin followed is that which has led to most of our discoveries; it is the encouragement of natural inquisitiveness under the best conditions; no short-cut and easy process would have produced dyes from tar. One of the biggest things in chemistry to-day is to learn how to make the teaching of chemistry *productive*, and a study of the lives of such men as Wöhler and Pasteur should conduce to this end. They teach the value of high training combined with faith, a combination seldom found in the individual American.

In inorganic chemistry the number of available metals has been doubled within a few years, so raising to the nth power the number of possible alloys. Many of these metals are coming into use. The isolation of calcium is less simple than that of zinc, copper, iron, or tin, and its properties are different, but as usual it is the differing properties which determine the new uses. During the war it was used as a generator of hydrogen to maintain a very high pressure of this gas inside certain deep-sea sound-detecting devices, the sea water itself acting as the other reagent. It is also used as a continuously reacting purifier for argon in the "Tungar" rectifier, which consists of a bulb made of a special new glass, a spiral of tungsten wire, an electrode of artificial graphite, a little argon, and some metallic calcium.

In the sphere of organic chemistry, is it not possible that a field will be developed directly from carbon itself as great as that of dyes from coal tar? The gates thereto were apparently opened when calcium carbide was first made; and when we reflect that this substance made possible the manufacture of acetone, alcohol, etc., we realise the possibility of making, by the same road, useful food as certainly as medicaments.

In agriculture we are attracted by the thought that our troubles with nature are sometimes due to our personal limitations, not to the limitations of nature; and there appears to be a fertile field for research into ways and means of reducing the amount of human labour expended upon the growing of crops. Some of the biggest things in chemistry are coming from research in biochemistry and hygiene.

The remainder of the address was an elaboration of the thesis that the spirit of research and the quest for truth in the experimental investigation of material phenomena lie at the very roots of human progress, both material and ethical.

LONDON.

At a meeting held on February 7, at Burlington House, with Mr. Julian L. Baker in the chair, a paper on "The Erosion of Bronze Propellers" was read by Dr. O. Silberrad. Recent investigations by a sub-committee of the Board of Inventions and Research have confirmed the author's previous conclusion that the deterioration of bronze propellers is due to mechanical causes. However, the Committee's conclusion that erosion is due almost exclusively to the collapse of vacuum bubbles ("water-hammer action") is not in agreement with the author's results, which show that after the surface of the metal has been damaged by this action further erosion is chiefly caused by frictional rub of the water.

Chemical analysis of the eroded portions of propellers shows that the composition of the eroded alloy is unaltered. Slight etching extending over considerable areas of the metal, which is sometimes observed when the propellers first come out of the water, is due to frictional rub and can be produced by high-pressure water jets impinging upon the surface of the metal. A determination was made of the daily loss of weight of a portion of a propeller exposed to the action of sea water, and it was inferred that over 5000 years would be required to produce by chemical action the excessive erosion frequently observed. The effects of electrical currents due to leakage and to mechanical stresses set up in the metal were found to be negligible. Microscopic examination of eroded propeller surfaces and sections showed deformation and breakage of the crystals composing the α constituent of the alloy, whilst those of the β constituent were practically unaffected. Macroscopic examination showed that the majority of eroded propellers were either small ones running at high speed or large ones transmitting great power, and that the presence of dirt in the castings was without effect. Investigation of many eroded propellers enabled a classification to be made based upon the location and extent of the areas eroded, each type being traced to conditions producing currents of water containing vacuum bubbles impinging upon the affected areas. Since the α constituent of propeller alloys was found to be much less resistant to erosion than the β constituent, the author investigated the production and properties of new alloys, but found that a copper-zinc brass possessing only β structure possessed undesirable mechanical properties. By the addition of small percentages of other metals an alloy with homogeneous β structure was obtained which had all the good mechanical properties of the older bronzes, and propellers made of it were found in practice to be very resistant to erosion.

MEETINGS OF OTHER SOCIETIES.

SOCIETY OF PUBLIC ANALYSTS.

At the annual meeting held on February 2, Mr. A. Smetham delivered the presidential address and officers were elected for the ensuing year.

Mr. J. L. Baker and Mr. H. F. E. Hulton described an iodometric method of determining the diastatic power of malts in which use is made of the quantitative oxidation of maltose to maltobionic acid by iodine in presence of sodium hydroxide. Results obtained on the same samples by this method and by that of Ling were given. The advantages claimed for this method are the greater accuracy with which the iodine titration may be carried out as compared with Fehling's solution, the elimination of an external indicator, and the possibility of using artificial light for the final titration.

In a paper describing experiments on the use of extract of red squill (*Scilla maritima*) as a rat poison, Mr. F. W. Smith showed that the most effective form was that prepared in water from an alcoholic extract of the fresh bulb of red squill, and that salicylic acid could be used as a preservative without fear of hydrolysing the glucoside.

A paper on the composition of Harrogate mineral waters, by Mr. W. Lawson, contained a summary of the analyses carried out in connexion with Prof. Smithell's survey of these waters, analyses dating back some 90 years being also given for comparison.

THE ROYAL INSTITUTION.

The first Friday Evening Discourse of the new session was delivered on January 28 by Prof. Sir James Dewar on "Cloudland Studies." The first part of the lecture was devoted to experimental illustrations of natural cloud effects produced with the aid of liquid air or liquid oxygen. This was followed by a discussion of the early work on solar radiation by Sir J. Leslie, D. Forbes, and Pouillet, and of the determination of the "solar constant," that is, the amount of heat energy measured in gram-calories which would impinge vertically on 1 sq. cm. of the earth's surface provided there were no intervening gases to intercept the rays. With the aid of his pyrheliometer, Pouillet did very accurate work, his value for the constant, 1·76, being within 10 per cent. of the result of the latest determination (1·93) by C. G. Abbott and his staff in America. Leslie and Pouillet also determined the zenith or black-body temperature of the sky, using different methods, but these early investigators were ignorant of several disturbing factors, such as the variation of the wave-length of the emitted energy with temperature. The maximum wave-lengths of the black-body radiation emitted at the respective temperatures of boiling water, solid carbon dioxide, boiling oxygen, nitrogen, hydrogen, etc., were given in a diagram which showed that at the lowest temperature yet attained with liquid helium—2° A.—the wave-length of the radiation should be 1465 μ or 1·465 mm. The original investigators were also ignorant of the transparency of gases and liquids to different radiations, and in this connexion the lecturer performed an experiment to show that liquid air is diathermanous to low-temperature radiations, and described how he had used his thermoscope, which is based upon this principle (*cf.* J., 1920, 35 R), to determine zenithal temperatures on the roof of the Royal Institution, the lowest value obtained being −42° C., in June last.

Observations made in America have indicated that the solar "constant" varies within about 5 per cent., a conclusion which was strikingly confirmed last year by Guthnick at the Berlin Observatory, who found that the variations in the intensity of the light reflected from Saturn were within 1 per cent. of the variations of the solar constant observed in America.

Dealing with the composition of the upper atmosphere at the end of his lecture, Sir J. Dewar stated that as yet we had no proof of the hypothesis that it consists of hydrogen and helium (and perhaps methane and traces of water-vapour), but the recent work of R. H. Goddard, of Clark University, Worcester, Mass., "On a Method of Reaching Extreme Altitudes" promised to solve the problem. Goddard's method consists, briefly, in sending up rockets containing multiple charges of very powerful nitro-explosive which are fired successively from the same combustion chamber. By this means a velocity of 7000 ft. per sec. can be obtained, and it should be possible easily to reach altitudes up to 50 miles. Theoretically, 200 miles should be attainable with 10—12 lb. of explosive, and 500 lb. of explosive should project the rocket into space.

It should not be difficult to obtain samples of the upper atmosphere by attaching to the rocket a suitable air collector, a mechanism to buoy it up for a short time at its maximum height, and a parachute to make it descend slowly. The efficiency of the Goddard rocket is about 50 per cent.

CORRESPONDENCE.

ORIGIN OF THE SOCIETY OF CHEMICAL INDUSTRY.

SIR,—With reference to Mr. D. de L. Herman's letter in your last issue, I had always regarded Mr. G. E. Davis as primarily responsible for the formation of the Society. I recall that while I was an assistant in the Chemical Department at Owens College, about the year 1879, there were frequent visits from Mr. Davis to Dr. Roscoe, and these visits no doubt related to negotiations, the objective of which was the formation of the Society of Chemical Industry.

The passage given below from the "Life and Experiences of Sir Henry Roscoe" (Macmillan and Co., 1906) explains these visits, and shows that the formation of a national rather than a local Society was advocated by Sir Henry, and thus the movement was given that broader outlook which has resulted in the present day world-wide extension of the Society. Speaking of the earlier enthusiastic workers, I would suggest that the name of Mr. Walter Weldon be added to those mentioned by Mr. Herman.

"The Society of Chemical Industry was founded in 1880. It originated with a few men interested in the Lancashire chemical trade, notably Eustace Carey, Ludwig Mond, and Edmund Muspratt. It was originally proposed that the Society should be a local one, the object being to bring together purely scientific men and those practically engaged in chemical industry in the Lancashire district. I felt strongly the importance of such a proposal, but I thought that if the thing were worth doing at all it should be a national and not a local institution. I gradually obtained adherents to this view, and the Society was founded on these lines. The first list showed that we had obtained already 360 members; at the present moment the numbers are over 4000. The history of the Society during the quarter of a century which it has existed has been one of constant progress and success, and its influence is felt not only in this country and our Colonies (Canada and Australia), but also in America, where we have one Section in New York and another in Boston.

"I was elected the first president, and many distinguished chemists, both scientific and industrial, have succeeded me in the presidential chair. The work which the Council has done in publishing a journal under the able editorship of my old pupil, Mr. Watson Smith, has been beyond praise."

Of the existence of the Faraday Club in Liverpool or of its activities I was not aware. It has an interest inasmuch as it shows that the example of the Tyneside chemists had spread to the Lancashire district. For in 1868 there was founded the Newcastle Chemical Society, of which Mr. I. Lowthian Bell, afterwards Sir Lowthian Bell, was the first president, and among his successors were the late Sir Joseph Swan, Dr. Lunge, and others well known to chemical industry. This society was active until 1893, when it was dissolved and transformed into the Newcastle Section of the Society of Chemical Industry, forming, in fact, the third Section of this Society.—I am, Sir, etc.,

P. PHILLIPS BEDSON.

Newcastle, Feb. 5, 1921.

PERSONALIA.

Sir Robert Robertson, Director of Explosives Branch, Research Department, Woolwich, has been appointed Government Chemist in succession to Sir J. J. Dobbie.

Dr. R. Anschütz is to retire from the chair of chemistry in the University of Bonn at the end of March. The chairs of pharmaceutical and organic chemistry in the Czech University at Prague have been filled by the appointment of Dr. Sterba-Böhm and Dr. Plzak respectively.

The first triennial award of the Kelvin Gold Medal has been made to Dr. W. C. Unwin for his pre-eminence in the branches of engineering with which Lord Kelvin's scientific work and researches were closely identified. The medal was established in 1914 as part of a memorial to the late Lord Kelvin and in association with the window placed in Westminster Abbey to his memory by British and American engineers.

The death is reported from Paris of Prof. E. E. Bourquelot, who served forty-four years in the Faculty of Pharmacy and twenty years as general secretary of the Society of Pharmacy, Paris.

NEWS AND NOTES.

FRANCE.

Industrial Notes.—*Metallurgy.*—The most important event of the past fortnight has been the dissolution of the Comptoir Métallurgique de Longwy with its subsidiary Le Comptoir d'Exportation des Fontes de Meurthe et Moselle. In well-informed circles this dissolution is held to be the outcome of the restoration to France of Lorraine. Prior to the war the "Comptoir" had absorbed practically all the French producers of cast iron; but owing to post-war changes a complete re-organisation became necessary, with Lorraine in the foreground. As co-operation could not be achieved, the "Comptoir" concluded that it could no longer maintain the leading position it formerly held, by virtue of which it suppressed intermediaries, secured the necessary *clientèle* for members of the syndicate, and distributed orders among the different works in such a way as to minimise distances between the producing centre and the client. All such co-ordination tended to diminish cost prices. It is anticipated that this syndicate will soon be resuscitated in some new form and on an enlarged basis.

Coal.—The present surplus of coal is due less to improved production than to the industrial slump; it is probably purely temporary, and when trade revives accumulated stocks will quickly disappear. It is rumoured that Germany will notify the Reparations Commission that her present supplies to the Allies are so crippling her economical and industrial position that she will not be able to supply the 2,200,000 tons stipulated for 1921, nor the arrears of 500,000 tons for 1920 due in January and February of this year. In order to find outlets for coal when control is removed, agencies are to be opened at Paris, Nancy, Strasbourg, Châlons, and Dijon for the coal raised in the Saar district. There will also be an agency in Switzerland.

Chemical Industry.—German competition is increasing and becoming more open not only in chemicals but also in plant and laboratory appliances; and the differences in price are so great that efforts to resist it are unavailing. Thus thermometers, balances, etc., are being offered at prices 33—50 per cent. below French prices and are being delivered within three weeks instead of the 12—18 months required by French makers.

Great surprise has been caused by the announcement that La Compagnie Nationale de l'Azote, which is an offshoot of La Compagnie Nationale des Matières Colorantes, of Les Établissements Kuhlmann, of La Société des Produits Azotés, etc., is going to use the "Badische" method of producing synthetic ammonia instead of the Claude process which is giving very satsfactory results at the Grande Paroisse Works at Montereau.

A credit of 150,000 francs has been voted by the Chamber for producing resin under Government control in the State forests of south-western France, in the vicinity of Bordeaux.

The production of the Alsatian potash mines in 1920 shows a notable increase. The quantity sold amounted to 200,000 tons of pure potash (K_2O), which represents one-fifth of the world's production in 1913.

Glass-making firms in France and in Belgium are very strongly affected by the present bad conditions in trade and by German and Italian competition. Several works have had to dismiss employees.

Manufacture of Paper from Alfa Pulp.—So far the United Kingdom has been the only country to use alfa, a product of French North Africa, for the manufacture of paper, but now, as a result of successful experiments, a French company is to be formed to produce the pulp. It is intended to acquire part of an explosives factory, situated near Avignon on the Rhone, and after 18 months to treat some 30,000 tons of pulp annually. The raw materials will be entirely of French origin, and the pulp produced will be dry, thus effecting economy in transport. Cellulose made from alfa is said to be suitable for the manufacture of smokeless powder. The exports of alfa from Algeria in 1917 were valued at 7,816,342 francs, of which the United Kingdom took 92 per cent., the share of France being less than 1 per cent. (*cf.* J., 1918, 301 R, 476 R).—(*Bd. of Trade J., Jan.* 13, 1921.)

AUSTRALIA.

Western Australia.

Porcelain Works.—Arrangements have been completed for initiating the manufacture of porcelain in Australia. In April next the Calyx Porcelain Co., Perth, will start erecting works at Subiaco which will cover three acres of land. Machinery to the value of £5000 has been purchased, and fifteen expert workers have been engaged.—(*Official.*)

Petroleum Exploration.—According to papers laid before the Parliament of Western Australia, the Anglo-Persian Oil Co., Ltd., has offered to form a Western Australian company with a capital of £100,000, of which £50,000 would be available for geological survey and boring. The company asked for legislation to be introduced next session to enable it to acquire leases of not less than 100,000 acres in the aggregate. The State Government acceded to the request for immediate legislation but would not consider leases larger than 600 acres each, to which the company replied that it was willing to explore for oil in Western Australia, but required large concessions similar to those granted to it in other parts.—(*Official.*)

Queensland.

Wolfram and Molybdenite Mining.—In order to save the wolfram and molybdenite mines near Cairns, the Chamber of Commerce of Cairns is urging the Commonwealth Government to acquire the properties as a national asset. During the war the deposits were exploited and the concentrates were shipped to the United Kingdom.—(*Official.*)

The Sugar Industry.—The twentieth annual report of the Bureau of Sugar Experiment Stations, issued December, 1920, states that never in the history of sugar growing in Queensland has there been so large an area under cane. The spring has opened up most favourably, and the prospects for next year are highly promising. Last year the yield of sugar from the cane attained a record, and this year it is also good, viz., about one ton of sugar from eight tons of cane, equivalent to a total yield of 163,000 tons.—(*Official.*)

Tasmania.

Electrolytic Zinc.—The Electrolytic Zinc Co. of Australasia is making large additions to its plant at Hobart, where 1200 men are now employed. It is anticipated that the company will shortly be able to export annually 10,000 tons of zinc oxide, 15,000 t. of zinc-lead oxide, 10,000—15,000 t. of lithopone, large quantities of rolled zinc sheets, and metallic silver and lead. The present output of zinc is 25 tons per day, and by November next this should be increased to 50—60 t. The current consumption is now 5700 h.-p., but when the full 30,000 h.-p. contracted for is available, the plant will be able to treat 100,000 t. of zinc concentrates per annum. Extensive warehouse and wharfage facilities are being supplied in order to cope with the expected increase in the export trade.—(*Ind. Aust. and Min. Stand., Nov.* 25, 1920.)

According to the *Times Trade Supplement* of Feb. 5, the above-named company has decided to cease production pending the increase of the plant capacity to 50 tons. The heavy fall in the price of spelter has led to this decision.

CANADA.

Projected New Paper Mill in British Columbia.—Plans are now practically complete for the erection of a large modern pulp and paper mill, to employ 1000 men, at Prince George, B.C., at a cost of $6,000,000. The capital is being supplied by interests in Eastern Canada and the United States.—(*Official.*)

Electric-Steel Smelting in British Columbia.—A new company, the British Columbia Steel Works, Ltd., has been formed to amalgamate the electric steel plants at Port Moody, Eburne, and Tudhope. For the present the three will continue operating, but later the work will be concentrated at Port Moody. —(*Official.*)

"Canadian Chemistry and Metallurgy" is the new title of *The Canadian Chemical Journal*, which has been chosen mainly because the older name too closely resembled that of various foreign journals that cover somewhat different fields—for example, specialised research. It is also announced that an additional paper, to be called *Canadian Dyer and Color User*, will shortly be isued from the same office.

SOUTH AFRICA.

Industrial News Items.—Asbestos deposits in the Haenertsburg District, Transvaal, are to be worked by the South African Asbestos Mines, Ltd., a newly formed company with a capital of £50,000.

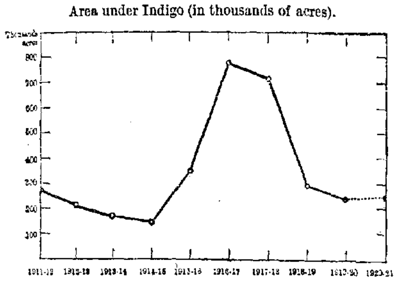
The fifth annual exhibition of the Chemical Metallurgical, and Mining Society of South Africa to be held at Johannesburg from March 9 to 21 will illustrate the latest developments in apparatu and machinery connected with chemistry, metallurgy and mining, and a section will be devoted t crude and manufactured products of the country.

The production of compressed oxygen and hydrogen will shortly be undertaken at Newtown, Johannesburg, by the Hydrogen, Oxygen and Plant Co., which will also make ammonia coils, condensers, etc., for refrigerating plants and undertake the welding of metals. A large works with two gasometers having a storage capacity of about 8000 cb. ft. is being erected at a cost of £35,000, and the plant will include 50 large cells capable of producing 3 million cb. ft. of gases yearly.—(*S. Afric. J. Ind., Dec.*, 1920.)

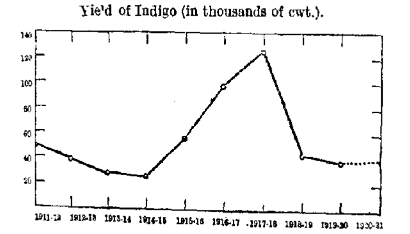
BRITISH INDIA.

The Indigo Industry.—The final general memorandum on the indigo crop for 1920-21, given in the *Indian Trade Journal* of December 31, 1920, states that the estimated total area under indigo is 238,400 acres, and the total yield 40,400 cwt., representing increases of 1·3 and 7 per cent., respectively, over the finally revised estimates of last year. The season was unfavourable, except in Madras, and the condition of the crop was reported to be fair. Of the total area under indigo in British India, 54·3 per cent. is in Madras (106,800 acres), 20 per cent. in the United Provinces, 14·7 per cent. in Bihar and Orissa, 9·3 per cent. in the Punjab, 1 per cent. in Bengal, and 0·6 per cent. in Bombay and Sind. The accompanying charts show the variations in the present figures of area and yield as compared with the finally revised figures of the last nine years.

Area under Indigo (in thousands of acres).



Yie'd of Indigo (in thousands of cwt.).



The exports by sea to foreign countries in each of the last five years have been (in cwt.):—1915-16, 41,932; 1916-17, 34,230; 1917-18, 31,062; 1918-19, 32,707; 1919-20, 32,687.

The imports of synthetic and natural indigo into the United Kingdom during the last five calendar years have been:—

	Synthetic indigo.	Indigo.	Total.
1915	11,240	25,157	36,397
1916	4618	30,527	35,145
1917	11,966	13,501	25,467
1918	2084	5287	7371
1919	2466	3701	6167
1920	4541	1603	6144

Of the total amount of natural indigo imported into the United Kingdom in 1919 (3701 cwt.), 2857 cwt. came from India, 445 cwt. from San Salvador, and the rest from other countries.

UNITED STATES.

A Museum of Chemical Types.—It is announced that the Smithsonian Institute has accepted the bequest of $25,000 left by Morris Loeb, chemist, for the establishment of a "Loeb collection of chemical types," which will include specimens of all new chemical substances and make them available to research workers for reference purposes. An advisory committee of chemists will be formed to deal with requests for the use of type material from the collection.—(*Oil, Paint and Drug. Rep., Jan. 3, 1921.*)

Potash in 1919.—The situation in the potash industry was very serious at the beginning of 1919. The high prices ruling during the war period had resulted in an increase of the annual output capacity to 100,000 short tons of pure potash (K_2O), and the invested capital was estimated at $25,000,000. Few of the larger plants had been paid for, and many were still under construction or had only been operated for a short time. One-third of the 1918 production was still unsold, prices had dropped from $5 per unit in November, 1918, to about $2·50, and the market was dull. Hence most of the producers closed down, at least temporarily, early in 1919, and some went out of business. Efforts were made to induce Congress to pass protective legislation but without success. As, however, imports remained small, prices were maintained and domestic output was readily absorbed.

Production in 1919 amounted to 110,243 short tons (28% K_2O) from 77 plants, compared with 207,686 t. from 128 plants in 1918. The alkali lakes of western Nebraska again provided the largest supply, but the output from the alunite deposits in Utah diminished, and the extraction from silicate rocks in Wyoming was suspended owing to technical difficulties. Only one kelp plant in addition to the experimental plant of the Bureau of Soils at Summerland, Calif., reported production. The Government has continued its experimental work, and the Bureau has made a survey of the occurrence of borax in potash materials. Few developments occurred in the production of potash from molasses-distillery waste, beet-sugar refineries, or wood ashes, and no production from wool washings was reported. The total production in 1919 was constituted as follows:—Nebraska lakes 29·2%, other brines 36·6%, Steffens waste water 11·7%, molasses-distillery waste 9·1%, alunite 7·4%, cement works 3·8%, wood ashes 1·2%, blast-furnaces, kelp, and silicate rocks 1·0%. Exports were very small, and imports amounted to 39,619 short tons (K_2O), compared with 7957 t. in 1918, and 270,720 t. in 1913.—(*U.S. Geol. Surv., Dec.* 8, 1920.)

Maize Oil.—Bulletin No. 904 of the U.S. Department of Agriculture contains an account by A. F. Sievers of the production and utilisation of corn (maize) oil in the United States, where it has been manufactured on a commercial scale for about 25 years. The production in 1918 was 49,545 long tons, of which about 70 per cent. was refined for edible purposes.

The oil is derived from the germs, which represent about 10 per cent. of the weight of the grain and contain about 50 per cent. of oil; the inclusion of the oily germ in the various products of maize-milling renders the latter liable to become rancid, so that removal of the germ is desirable; this is carried out on a large scale, though whole grain is still milled, particularly in the Southern States. Degermination is effected by dry-milling in the manufacture of hominy products (grits, flakes, meal, and flour) and by the wet process in the manufacture of starch and glucose.

In the dry process the cleaned grain is sprayed with water and treated with steam till it contains about 20 per cent. of water, and is then passed through a degerminating machine, consisting essentially of a drum tapering horizontally, studded with cone-shaped projections, and revolving at 700 revs. per minute inside a casing with similar projections; in passing through the machine the kernel is torn and shredded, the husk and germ are loosened, but the starchy portions of the grain are not ground appreciably. After separation of the various products the germs are dried until the moisture content is about 14 per cent. In the wet process of degermination the grain is steeped for 36—40 hours in a 0·2 per cent. solution of sulphurous acid in wooden vats, which are in some cases arranged

so that the steeped grain can be removed from the bottom of the vat and fresh grain charged in continuously. The steeped grain is then drained and passed through mills which shred it, loosen the husks from the endosperm, and free the germs. The latest type of wet-degerminator consists of two circular vertical plates mounted (inside a casing) on a horizontal axis. Only one plate is geared to motor and revolved; in earlier types both plates were revolved.

The shredded grain is mixed with a large bulk of water and run to floating-vats, where the germs rise to the surface and pass over the end of the vats together with starch, which is removed by washing in perforated reels; the wet germs are then pressed to remove excess moisture, and finally dried to about 15 per cent. of moisture in steam-heated rotary driers.

Germs produced by the dry process are mixed with a good deal of the other portions of the grain; they contain an average of about 18 per cent. of oil and yield a cake with 5—7 per cent. of oil; wet-process germs, being more completely separated, contain about 45 per cent. of oil and yield a cake with 8—12 per cent. of oil.

The processes of oil-crushing and refining are similar to those used for other oil-bearing materials, though it is of interest to note that hydraulic presses have been almost entirely replaced by expellers which are more economical to run, partly owing to the present high cost of press-cloths; solvent extraction is sometimes employed. The oil cake is generally mixed with other products of maize-milling and sold for feeding purposes.

Crude maize oil is usually of good quality and low acidity, oil from dry-process germs being in some cases suitable for edible purposes without refining, and the average free fatty acid content of oil from seven mills being 1·11 per cent. by the dry process and 2·39 per cent. by the wet process; the acidity may, however, rise much above these figures, and oil from the 1917 crop averaged nearly 10 per cent. owing to the grain having been immature.

Maize oil has been used for many purposes, one of the chief being in the manufacture of rubber substitutes; it is still employed in soap-making, but most of the oil now produced is refined for edible purposes, the demand for which is evidently increasing. The elimination of the brewing industry, which is a large user of maize products, may cause a decrease in the production of the oil, though the increased demand for "corn-sirup" and other sugars may lead to increased milling of maize.

Bauxite and Aluminium in 1919.—The quantity of bauxite marketed in the United States in 1919 was 376,566 long tons, valued at $2,201,747 at the mines, a decrease of 38 per cent. in quantity and 36 per cent. in value compared with 1918. Arkansas, with an output of 333,490 t., was the chief producing State. The domestic bauxite marketed was utilised as follows:—For aluminium 272,270 t., for chemicals 67,842 t., for abrasives 35,395 t., and for refractories 1059 t. Imports of bauxite amounted to 6082 t., and exports to 17,701 t. Aluminium production, valued at $38,558,000, showed a decrease of 6 per cent. compared with 1918, which was due to accumulation of stocks. It is reported that plants for producing both aluminium metal and manufactured articles have been extended. The Aluminium Co. of America is building new plate mills at Alcoa, near Maryville, Tenn., and is enlarging the mills at New Kensington, Pa. Plants for making aluminium foil and powder have also been enlarged. There are now 23 plants producing aluminium sulphate, of which five are at municipal works. The total output of aluminium sulphate in 1919 was 200,034 short tons, and the average price was $33·80 per ton; three plants produced 4806 short tons of the chloride and 8 plants produced 17,091 t. of alums, mainly ammonium and sodium alums (*cf.* J., 1920, 288 R).—(*U.S. Geol. Surv., Aug.* 30, 1920.)

GENERAL.

The Association of Swiss Leather Chemists.—The Association Suisse des Chimistes de l'Industrie du Cuir was founded in 1918 as an independent association with objects similar to those of the Society of Leather Trades' Chemists. It has now about fifty Swiss members. At the last annual meeting, held in Lucerne in 1920, the Association decided, among other things, to take up the fight against the warble fly pest in Switzerland, and at a special meeting, held on January 15 last, the president submitted a scheme for the appointment of a Swiss committee to investigate this problem as part of the larger question of hide and skin deterioration. The scheme was accepted and a committee appointed. The Swiss Government and the Swiss Farmers' Association were represented at the meeting, and the president intimated that he had received a letter full of encouragement from the secretary of the Warble Fly Committee of the British Ministry of Agriculture and Fisheries. Another question discussed was that of official analyses in the leather trades, with a view to forming a special committee to study this subject in Switzerland, if necessary in collaboration with the existing committees of the International Associations.

The Dye Industry in Spain.—The Spanish coal-tar dye industry, centred in Catalonia, developed considerably during the war owing to the absence of German competition. Two old-established firms in Barcelona—J. Pellicer and L. Sagnier—are now producing Delta, Congo, and other standard colours on a competitive basis, but neither these firms nor any of those recently established can produce the special dyes for which Germany is famous. The most important new companies are the Sociedad Española de Productos Quimicos (*cf.* J., 1919, 32 R), which is supposed to control the market in Sulphur Blacks, and the Industria Quimica Nacional, which so far has only manufactured sulphuric and hydrochloric acids, etc., but is negotiating with German firms with a view to acting as their agents on the Spanish and South American markets. The Anilinas y Productos Quimicos company, of Barcelona, is reported to be closing its works, as it is unable to produce at a profit owing to lack of raw materials and *personnel;* and the Quimica Tarasense company mainly produces chrome colours from raw materials imported from America. Except in the case of the simple coal-tar colours, it may be said that the recent efforts of the Spanish industry have come to grief, and that German colours still retain their supremacy.—(*Z. angew. Chem., Nov.* 26, 1920.)

The Glass Industry in Lorraine.—The glassworks of Lorraine are situated at Dreibrunnen (near Saarburg), Chateau Salins, Forbach, St. Aurin (near Lörchingen), Götzenbruck, Meisenthal, and Münzthal (near Bitsch). The three last are the most important. The Münzthal works is now producing ordinary glassware, fancy wares being in small demand; it has the largest glass furnace in the world, with 24 pots. The Meisenthal factory, employing 500 men, has been doing well, and has recently spent 500,000 fr. on plant extensions, etc. The Götzenbruck factory is the largest spectacle-glass works in the world; it employs 800 men, but some of these have been dismissed owing to trade depression; it also manufactures watch and window glass. The Lorraine glass industry, although prosperous on the whole, has been affected by its isolation from the German market, and part of its trade has been lost to Germany and Japan.—(*Z. angew. Chem., Dec.* 24, 1920.)

German Chemical Industry in 1920.—During the irst half of the year the production of chemicals was ery seriously affected by shortage of raw materials ınd coal, and the foreign demand, stimulated by he low rate of exchange, could not be satisfactorily ıet. These conditions created a danger of German hemical firms coming under foreign domination. ıhe large companies met the altered circumstances by making large increases in capital and at the same time drawing themselves into closer association. Owing to this increase, the total capital of the most important German chemical companies amounted to 1·9 milliards of marks at the end of 1920. The very sudden upward move in prices of chemical products in January-March gave rise to the most rampant speculation, but ended disastrously for both home and foreign speculators after the Kapp insurrection. It would have been much better if the development of the export trade had taken place more gradually, as the sudden violent demand could not be satisfied owing to want of coal. In the latter part of the year, when coal supplies began to improve, production could not be developed owing to difficulties in selling. Many foreign contracts were cancelled as the value of the nark rose, and the threat of a trade crisis, stimuated by the reported sudden drop in the prices of oreign chemicals, has persisted over the end of the year. In fact, the present year opens with prospects of a crisis more serious than any which has been experienced since the 1860's. There is a doubt whether recent dividends were justified, paper money has never been so depreciated, and never has the necessity for ample reserves to cover repairs and replacements been so vital. The dividends of 14 to 20 per cent which were declared in spite of the large and growing demands for State taxes and workers' wages, were designed to support the heavy increases in capital; they were only justifiable as a livision of war profits, after writing off the cost of extensions and new plant.

Problems connected with the re-organisation of the chemical industries are being dealt with by the Reichsarbeitsgemeinschaft Chemie, Berlin; the most mportant of these was that of coal supplies, for owing to the deliveries due to Allied countries under the peace treaty the requirements of German industry could not be met by more than 50 per cent. at most. The coal-tar colour and soda industries, which employ, either directly or indirectly, over 3 million workers, were very hard hit. The Solvay works at Würselen and Rheinsberg were shut down in January for want of coal, and similar trouble extended through all branches of the industry during the whole spring, and only in the summer did any improvement set in. Closely dependent on the coal problem is the supply of raw materials such as coal-tar products, salt, lime, alcohol, etc. These created grave difficulties in the past year, and the prospects for 1921 are not much better, since large quantities of benzol, coal tar and ammonium sulphate have to be delivered to France under the agreement of January 10, 1920.

The question of the socialisation of the coal mining industry is a disturbing factor, and a resoluion condemning the proposal was passed unaniously at a meeting of the chemical trades held t Munich in September. The tendency of the proosal is to reduce production in the mining indusry and to increase prices, thus crippling the hemical industries in their endeavour to rehabilitte German trade and meet foreign competition the world's markets.

The compulsory control of the chemical industry, hich so rigidly enforced during the war, has now en abolished for internal trade, but it was relved on November 24 that restrictions on the port trade should be continued for a time. In ıny cases export licences have already been olished.

Wages and salaries were increased two- or three-fold over those paid in 1919, but recently difficulties and disputes have arisen in the attempt to reduce wages by 10—15 per cent. There is little sign of the hoped-for fall in the cost of living, and demands for further increases in wages must be expected.

Organisation in chemical industry has developed to a remarkable extent during the past year, and industrial scientific research has been furthered by the foundation of many new institutes and societies. The exclusion of Germany from many of the world markets makes it imperative that the development of her chemical industry should proceed on the lines of concerted action and high-quality production.—(*Chem.-Zeit.*, *Jan.* 1, 1921.)

The Beet-Sugar Industry in Bulgaria.—As yet only beet sugar is produced in Bulgaria, but experiments with sugar cane are now in progress, and prospects appear to be favourable. Although the area planted to sugar beets in 1919 was only 21,414 acres, a decrease of 18,167 acres on the 1918 area, the total production was 11,861 metric tons, an increase of 8465 t. There are refineries in Sofia, Rustchuk, and Gorna Orchovitza, each with a capacity of 120 to 150 metric tons of raw sugar per 24 hours. No sugar is exported, but 4953 t. was imported in 1919, mainly from Czecho-Slovakia.—(*U.S. Com. Rep., Dec.* 6, 1920.)

The Mineral Output of Italy in 1919.—The Italian mining industry made considerable progress during the war, the number of workmen employed and the value of the production having increased from 46,412 and £3,860,000 (£1=25 lire) in 1914 to 58,871 and £14,790,138 in 1918, respectively. The chief mining districts are situated in the provinces of Caltanissetta (Sicily), Florence, Arezzo, Grosseto (Tuscany), Cagliari, Sassari, and Iglesias (Sardinia), whilst others of lesser importance are situated in the provinces of Bergamo, Brescia, and Turin. The full extent of the mineral resources of Italy is not known and an extended study is required. Details of the output of minerals and metals for 1918 and 1919 (in metric tons) are appended:—

	1913.	1919.
	Metric Tons.	
Minerals:—		
Iron ore and manganiferous iron	603,116	450,729
Manganese ores	1662	23,592
Copper ores	89,847	16,393
Lead ores	44,654	11,937
Iron and copper pyrites	317,334	372,474
Mercury (metal)	1004	548
Sulphur	406,406	226,126
Coal and lignite	701,079	1,158,542
Petroleum	6572	4851
Marble	509,342	265,744
Metals:—		
Pig iron	426,754	239,716
Iron and steel	933,500	731,823
Copper	2091	1243
Zinc	—	1282
Lead	21,674	16,530
Antimony	76	30
Aluminium	874	1,673

The total capital invested in the Italian mining industry at June 30, 1919, was £13,472,278.—(*Bull. Dept. Tr. and Com., Can., Nov.* 15, 1920.)

Dutch Guiana in 1919.—The production of gold is steadily declining, although dredging prospects in the Marowyne river are considered good. Bauxite mining is regulated by a new law, which provides for concessions lasting not more than 50 years and limits the area held by any one company or individual to 308,750 acres. Preparations for the mining and export of bauxite are going forward rapidly. Mercury has been found in a number of places near the Marowyne River, and in co-operation with the Government a Dutch company is exploring large areas said to contain deposits of high-grade iron ore. Balata production has decreased, in spite of good prices, and as areas worth exploiting are becoming more inaccessible from the coast,

the industry is gradually passing into the hands of two or three large corporations.—(*U.S. Com. Rep., Suppl., Oct.* 4, 1920.)

The Mica Industry in Brazil.—H. M. Commercial Secretary at Rio de Janeiro reports that excellent sheet mica is produced in Brazil in the State of Minas Geraes (municipality of Pecanha). Large quantities of good-quality mica also occur in the State of Sao Paulo, in Iguape, Itapecirica, and in the Serra do Mar mountains. The development of the industry was formerly greatly handicapped by inadequate transport, but apparently this is now largely counterbalanced by increased working costs in India and elsewhere, and by the higher price of the product. The production of mica in Brazil has risen from 50·8 metric tons in 1915 to 154·35 t. in 1919.—(*Bd. of Trade J., Dec.* 16, 1920.)

Proposed Pulp and Paper Manufacture in Portuguese E. Africa.—H.M. Consul-General at Lourenco Marques reports that a concession has been granted to the Cia. Portuguesa de Papel Mocambique giving it the exclusive right to prepare pulp from native and foreign vegetable matter, and to manufacture paper and parchment in the province of Mozambique for a period of ten years. The company is to erect a factory at Ressano Garcia, near the Transvaal frontier, and utilise tambuki grass, and possibly wood, as raw material. The syndicate which holds the concession for the manufacture of pulp from baobab trees in the Quilimane and Tete districts has been unable to sell its products to paper-manufacturers in the United Kingdom, in spite of favourable technical reports. Some time ago it contracted to supply a Norwegian pulp company with 40,000 tons of material on a royalty basis, and since then it has received numerous inquiries from Germany and the United States.—(*Bd. of Trade J., Dec.* 16, 1920.)

A New Process for Drying Peat.—A company, the Oy. Hydroturve A.B., has been formed in Finland for the purpose of exploiting a new labour-saving process for drying peat. In the process the peat in the bed is reduced to mud by a jet of water under high pressure, and the mud is pumped on to a drying field by an electrically-driven pump fitted with a cutting apparatus. Roots, etc., are removed by means of a special device and, after drying, the mud is cut up into uniform sizes. Peat ("hydro-turf") prepared by this process, which is of Russian origin, is said to dry more quickly than ordinary peat.—(*U.S. Com. Rep., Dec.* 30, 1920.)

The Institute of Metals.—The annual general meeting of the Institute of Metals will be held on March 9 and 10 next at the Institution of Mechanical Engineers, Storey's Gate, Westminster. The meeting will commence on each day at 10.30 a.m., and the list of papers to be read includes:—March 9. "Stages in the Re-crystallisation of Aluminium Sheet on Heating, with a Note on the Birth of Crystals in Strained Metals and Alloys": H. C. H. Carpenter and F. Elam. "Some Notes on Calcium": P. H. Brace. "Plastic Deformation of Some Copper Alloys at Elevated Temperatures": C. A. Edwards and A. M. Herbert. "The Action of Reducing Gases on Heated Copper": H. Moore and S. S. Beckinsale. March 10. "The Season Cracking of Brass and other Copper Alloys": H. Moore, S. Beckinsale, and C. E. Mallinson. "The Constitution of the Alloys of Copper with Tin, Parts III. and IV.": J. L. Haughton. The annual dinner will be held at the Trocadero Restaurant on March 9, at 7.30, and on the afternoon of March 10 a visit will be made to the National Physical Laboratory, Teddington. As previously announced, the May Lecture will be given on May 4 by Prof. T. Turner on "The Casting of Metals."

It is announced that arrangements have been made for the publication of an index to the first twenty volumes of the Institute's Journal, and members are asked to notify the Secretary if they intend to purchase a copy, the price of which will probably be 10s. 6d. The next ballot list of applicants for membership will be issued on February 24 and applications should be sent in by the day before. Special concessions are offered to those who are elected members on the next ballot.

Lectures on Catalysis at the Royal Society of Arts.—A series of three Cantor Lectures will be delivered during February by Dr. Eric K. Rideal on "Applications of Catalysis to Industrial Chemistry." The syllabus is as follows:—

Lecture I. Feb. 14.—Introduction: classification of catalytic action: theories of catalysis; technical difficulties.

Lecture II. Feb. 21.—Processes of Oxidation:—Sulphuric acid: nitric acid: chlorine: catalysts in the gas industry: sulphur recovery: surface combustion: incandescent mantles: organic industries: formaldehyde: drying oils: linoleum: oxidation of hydrocarbons.

Lecture III. Feb. 28.—Processes of Hydrogenation:—Preparation and purification of hydrogen: methane: hexahydrobenzol: oil-hardening: synthesis of ammonia: the cracking of oils: synthetic rubber. Hydrolytic Processes:—Saponification: glucose: alcohol: acetic acid: acetone and ether.

The lectures begin at 8 p.m.

LEGAL INTELLIGENCE.

ALLEGED BREACH OF CONTRACT *re* SALE OF COAL-TAR PITCH. *Erlebach and Co. v. Gatty, Saunt and Co.*

In the Court of Appeal on January 21, Messrs. Gatty, Saunt and Co. appealed against a judgment of Mr. Justice Bailhache, awarding Messrs. Erlebach and Co. damages for alleged breach of contracts relating to the sale of coal-tar pitch. Plaintiffs (Messrs. Gatty, Saunt and Co.) contended that some of the pitch supplied was not coal-tar pitch, and was unsuitable for briquette manufacture, for which, to the defendants' knowledge, it was required, and for which they gave an assurance that it was suitable. Defendants denied having any knowledge that the pitch was required for the purpose stated, or having given any warranty, and did not admit that the pitch was not coal-tar pitch. Mr. Justice Bailhache found for the plaintiffs on both points, viz., that the pitch supplied was blast-furnace coal-tar pitch, and was therefore not good delivery; and that plaintiffs were told that the pitch was suitable for briquette manufacture.

In dismissing the appeal, Lord Justice Bankes, Scrutton and Adkin found that, although there was no well-known and accepted meaning of the expression "coal-tar pitch," blast-furnace pitch was excluded from the terms of the contract. Firms that stood high and desired to be beyond reproach would not sell blast-furnace pitch as coal-tar pitch. On the other hand, they were satisfied that plaintiffs had informed defendants that the pitch was required for briquette-making, and this implied a warranty. The judgment in plaintiffs' favour must therefore stand.

PUBLICATION OF A DESIGN. *Gunston, Green and Simpson, Ltd., v. Winox, Ltd.*

In the Court of Appeal, on February 28, the Master of the Rolls and Lords Justices Warrington and Younger allowed an appeal by Messrs. Winox, Ltd., from a judgment of Mr. Justice Astbury given at a suit of Messrs. Gunston, Green and Simpson, printers, of Farringdon Avenue, E.C.

By the judgment complained of Mr. Justice tbury granted an injunction to restrain the dedants from infringing plaintiffs' design (a cardard cut-out portraying a nurse carrying a tray th wine and bunches of grapes). Plaintiffs' case is that, having originated the design and applied r registration, they sold it to Liebig's, Ltd., for vertisement purposes, but that before any copies the cut-out were delivered they found that dedants were using a design which they considered infringement. Mr. Justice Astbury held that e manager of Winox, Ltd., having been shown the sign in confidence, had something similar prered to his order from other printers, and granted e injunction.

The Master of the Rolls, giving judgment, said he sagreed with Mr. Justice Astbury with regret, cause he thought the defendants had played the aintiffs a very dirty trick. But before the design is shown to the defendants, and before it was restered, it had been shown to another firm with the ew of obtaining an order, and that constituted a iblication within the meaning of the Patents and esigns Act, and enabled the defendants to escape e consequences of the conduct of their manager. e appeal must be allowed. The Lords Justices ncurred.

REPORT.

EPORT ON THE INDUSTRIAL AND ECONOMIC SITUATION IN GERMANY IN DECEMBER, 1920. *By* J. W. F. THELWALL *and* C. J. KAVANAGH. *Pp.* 79. *Department of Overseas Trade. London: H.M. Stationery Office.* 1920. [*Cmd.* 1114. 9d.]

Although conditions in Germany have generally proved during the past two years, the state of blic finance has become desperate owing to the er-increasing issue of paper currency. In March, 20, trade and industry were plunged into sudden gnation, which still continues, although the tical stage is probably past. The high dividends id for the year 1919 seem to suggest successful ding, but some of the satisfactory balance sheets re due to large payments by the State on comted war contracts. The outstanding features of past year were the formation of combines and operation with foreign groups; the former movent has spread very widely, especially in the iron, el, and coal industries. No official statistics of eign trade have been published. The labour uation, as a whole, has improved, but it may ert in times of stress arising from failures due to es in exchange consequent on falling world ces, or from increased taxation.

Complaints of the shortage of coal are not irely confirmed by the published figures of protion and distribution. Thus it was officially ted that the proportion of supply to requirents in August last, compared with that in gust, 1913, was 64 per cent., but the issued tistics indicate 82 per cent. Only 88 per cent. the coal requirements of the chemical industry tated to have been satisfied in May, and 63 per t. in August, 1920. Owing to the increased conption of lignite (now 132 per cent. above that 1913), alterations have had to be made in firing ems and greater space is required in transport; ain power stations, nitrogen plants, etc., use it usively. There have also been improvements in utilisation of waste gases, peat, and other lowde fuels. To sum up, although German industry ot abundantly supplied with coal, it is by no ns threatened with annihilation from lack of ; difficulties are only temporary and coal uction is improving.

he iron and steel industry has recovered rapidly a measure of stability has been attained since April, 1920, when the Eisenwirtschaftsbund came into operation. As most of the iron ore consumed has now to be imported, attention will be directed more to working up iron and steel into the highest types of manufacture rather than producing semi-finished products, *e.g.*, pig iron, blooms and billets, as in the past. One of the most important combines (*cf.s.*) is the Rhine-Elbe-Union which controls a capital of over 500 million marks and employs 200,000 workers.

The non-ferrous metals industry has re-established itself on old lines. The aluminium industry is row controlled by the Vereinigte Aluminiumwerke A.-G. and has enjoyed a good export trade; home deposits of bauxite have been developed for chemical rather than metallurgical uses, and supplies formerly obtained from France are being derived from Dalmatia.

Little has been published of late concerning the chemical industry, and the dye industry in particular, save complaints about the coal shortage and the high cost of raw materials and labour—difficulties which have led to further amalgamations. Several Silesian firms have combined under the title "Chemische Werke Oberschlesien G.m.b.h.," with the object of working up their total production of tar, benzol, and ammonia. The chemical industry has survived the most critical stage after the war, and helped by its consolidation, organisation and experience, is trying to regain its old markets. The H. J. Sloman Saltpeter A.-G. (*cf.* J., 1920, 281 R) is to sell its overseas interests to the Salitrera Tocopilla company for 16,320,000 mk., its shareholders having the right to acquire an interest in the new company. In the early part of the year the potash industry improved, crude salts were in plentiful supply, but salts high in potash were scarce owing to exportation and lack of coal. Towards the autumn, the trade with America declined and Alsatian competition began to be felt. The consumption of pure potash (K_2O) in 1919 was 812,002·4 metric tons compared with 1,110,369·4 t. in 1913, and 1,001,664·3 t. in 1918, and the sales from January to October, 1920, were about 800,000 t. Sales of manufactured potash compounds have notably decreased. Whereas potash prices have risen by an average of only 441 per cent. since 1914, those of coal, iron, food and wages have risen by 1600, 2700, 1200 and 1000 per cent., respectively. As the home price of potash is below cost, extra profit must be made on foreign sales. Since 1918 a potash council (Reichskalirat) of a socialistic nature has been formed to enable employers, consumers, and workmen to meet and discuss conditions of labour, wages, etc. (*cf.* J., 1920, 100, 116, 132, 235, 274, 446 R).

The seed-crushing industry was in a serious position in September owing to stocks having become exhausted through official interference. Some German and Dutch firms are forming a company with a capital of 100 million mk. (*cf.* J., 1920, 445 R) in order to secure adequate supplies of fats and to overcome difficulties of exchange in purchasing raw materials; the purchases will be effected through the Dutch parent undertaking. Of the 102 mills associated with the German Economic Union of Oil-pressing Mills, a large majority is under foreign (mostly Dutch) influence.

An industrial organisation ("Reichswirtschaftsstelle für Kunstseide und Stapelfaser"), in which makers, consumers, and employees have equal representation, was formed in November to regulate production, sales, and prices in the artificial silk industry, and its first action was to abolish State control. The production of artificial silk has so increased that it can now satisfy the home demand.

The report contains fifteen appendices giving statistical information relating to finance, fuel, wages, unemployment, industrial combines, foreign trade, etc.

OFFICIAL TRADE INTELLIGENCE.

(From the Board of Trade Journal for January 27 and February 3.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of Firm or Agent.	Materials.	Reference number.
Canada	Chemicals, dyes, oils, glue, fertilisers, dry colours, whiting, precipitated chalk	123
"	Metals, leather, china, porcelain ..	154
"	Bessemer blue-annealed steel sheets	*
Egypt	Soap	163
"	Paper, bristol-board, ink, antimony, tin, pig lead (tenders for).. ..	
South Africa ..	Paper	127
Belgium ..	Paint, varnish	132
" ..	Metallurgical products	133
" ..	Pitch	169
Norway ..	Leather	140
Switzerland ..	Black and galvanised sheets, tinplate	143
China	Linseed oil	174
Persia	Drugs, soap, window glass	176
United States ..	Barytes, lithopone, dry colours, cresylic acid	177
" ..	Mica	178
" ..	Glass, pottery, china, porcelain ..	181
" ..	Scientific and optical instruments..	182
" ..	Earthenware, pottery	183
" ..	Pottery, tiles	184

* The High Commissioner for Canada, 19, Victoria Street, London, S.W. 1.

Markets Sought.—A Canadian firm wishes to get into touch with U.K. importers of cyanide for the extraction of gold. [Inquiries to the Canadian Government Trade Commissioner, 73, Basinghall Street, London, E.C. 2.]

A firm in Ceylon and Southern India able to export medicinal plants, vegetable fibre, copra, rubber and oil-seeds wishes to hear from U.K. importers. [128]

TARIFF, CUSTOMS, EXCISE.

Australia.—Recent customs decisions affect iron and steel sheets, carbonate, bicarbonate and silicate of soda, and explosives.

Austria.—Customs duties when paid in bank notes must be paid at 50 times the rates prescribed in the tariff, as from January 1.

Belgium.—The conditions affecting the import and export of sugar are given in the issue for January 27.

Cocoa butter, salt, and soap may now be exported without licence.

British India.—The duty on opium imported into the Punjab and the North-West Frontier Province is fixed, as from April 1, at 36 Rs. per seer unless produced in any State under the control of the Punjab Government, in which case the duty will be 27 Rs. per seer.

Colombia.—Export of gold and silver is now permitted. The customs duties have been modified on, *inter alia,* alcohol, certain alcoholic beverages, and printing paper.

Denmark.—Export prohibitions have been withdrawn from oil-cake, margarine, vegetable oils for the manufacture of margarine, eleo stock, oleo-oil, certain oil-seeds and oleaginous products.

Egypt.—The export of coal-tar derivatives suitable for the manufacture of explosives is prohibited.

The export is prohibited, except under licence, of crude alcohol, groundnuts, silver, butter, certain drugs, chemical fats, edible fats, cotton oil, sesame oil, yeast, gold, crude paraffin, molasses, sugar, and oil-cakes.

France.—The customs duties on certain kinds of paper have been reduced.

The prohibition of the export of pure vegetable oils has been withdrawn, but the export of oil-cake is still subject to licence.

French Equatorial Africa.—An export duty of 5 per cent. *ad valorem* has been levied on palm oil and palm kernels.

Italy.—The customs duty on mineral oils, except heavy oils, has been increased by 50 per cent.

Benzol and other light coal-tar oils for use as raw materials for the manufacture of artificial organic colours, varnishes or lacquers, may be admitted at the reduced rate of 2 lire per 100 kg. if denatured by specified methods.

Ammonium nitrate for use as a fertiliser may be admitted duty free if adulterated and upon proof of its use for this particular purpose.

The temporary suspension of the import duty on white paper, in rolls, for newspapers is extended until March 31.

The use of white phosphorus for the manufacture of matches, and the import of matches containing white phosphorus, are prohibited as from January 1. The import of white phosphorus for other uses is subject to the permission of the Minister of Finance.

The import of motor spirit, matches, saccharin, and sugar is reserved to the State.

Among the articles for which import licences are still required are glassware and perfumery.

The export of the following is prohibited:—Bricks, tiles, cement, charcoal, copra, animal and vegetable fats, feculae, margarine, condensed milk, fertilisers, metal scrap, certain metallic ores, nickel, newsprint paper, glucose, molasses, sugar, caramel, certain oils, various potash salts, pyrites, quinine, pure spirit, copper sulphate, tanning extracts, toluol, etc.

Japan.—The duty-free admission of mineral oils is only applicable to oils to be used for certain specific purposes, *e.g.*, the ceramic and metal-heating industries.

Memel Territory.—The customs *régime* is given in the issue for January 27.

Netherlands.—Export prohibitions have been withdrawn from engine and lubricating oil, firebricks, coal tar and its residues.

New Zealand.—As from December 1, 1920, packages containing cream of tartar substitute must be labelled with the name or names of the substances most generally understood by the public.

The prohibition of the export of sheep skins has been revoked.

Norway.—The import of alcohol is prohibited.

Portugal.—A revision of the Customs tariff is projected. The proposed new rates are not very different from the tariff of 1892, but the duties are leviable entirely in gold. Payment, however, may be made by means of "gold warrants."

South Africa.—Sugar imported from Belgium and Holland is subject to a surtax.

Spain.—The rate of surcharge on customs duties when paid in Spanish silver or notes of the Bank of Spain is fixed for the month of February at 45·03 per cent.

Trinidad and Tobago.—Articles subject to export tax include sugar, molasses, syrup, rum, cocoa, coconuts and copra.

COMPANY NEWS.

GAS LIGHT AND COKE COMPANY.

Speaking at the annual meeting on February 4, Mr. D. Milne Watson, the Governor, announced that the company would shortly sell gas on a calorific basis, and that the standard price would be 1s. 3·2d. per therm. The calorific value to be declared was 475 B.Th.U., and the actual price would be 1s. 2d. per therm, corresponding to the present price of 5s. 6d. per 1000 cb. ft. of gas. The sliding scale had now been re-established, but on a different basis, and it should be possible to raise the dividend from £3 to £4 13s. 4d. per cent. per annum. Mr. Milne Watson dealt at length with the reasons why the price of gas had recently been raised by 10d. per 1000 cb. ft., the chief of which was the very sharp decline in the price of residuals. He also reviewed in detail the events of the past year, stating that the output of gas had reached the record total of 32 thousand million cb. ft., that the number of customers had increased by 9000, and that the coal consumed had risen to over 2¼ million tons. Both the increased demand for gas and the good prices obtained for residuals (until near the end of the year) were satisfactory, but on the other hand the company had suffered from the rise in the cost of coal, the very high price of oil, the enormously increased wages bill, the necessity for spending large sums on repairs and maintenance, and the slump in the price of residuals following the coal strike. The company was extending its manufacture of intermediates in order to meet the new situation created by the passing of the Dyestuffs (Import Regulation) Act.

Amalgamation in the Photographic Trade.—An amalgamation has been arranged between the following firms:—Paget Prize Plate Co., Watford; Rajar, Mobberly, Cheshire; Marion and Co., Soho-square and Southgate; Marion and Foulger, Bedford; A. Kershaw and Son, Leeds; Kershaw Optical Co., Leeds; Rotary Photographic Co. (1917), West Drayton. The new company is called the "Amalgamated Photographic Manufacturers, Ltd.," and its authorised capital is £1,100,000, divided into 100,000 seven per cent. cumulative preference shares of £1 each, 600,000 ten per cent. participating cumulative preference shares of £1 each (250,000 of these are now being offered at par), and 400,000 ordinary shares of £1 each.

The British Cellulose and Chemical Manufacturing Co., Ltd., has received a report from Messrs. Clavel and Lindenmeyer, dyers, of Basle, Switzerland, describing the results of tests on the dyeing properties of the cellulose acetate silk made at Spondon. According to the report, this silk shows a remarkable chemical affinity for dyes, and no pre-treatment is required even in the case of dyes insoluble in water. The Basic, Azo, Acid, Alizarin, and other dyes can be used successfully, and the dyed silk thus obtained is fast to light and wash proof; the basic dyes in particular show an unusual fastness to light. Weaving tests have shown that the great elasticity of the silk enables it to be worked through the loom with ease, whether used as warp and weft, or as one of these, or in conjunction with natural silk; those responsible for these tests remarked on the absence of breakages and called attention to the fine "scroop" and rich appearance of the product.

British Cyanides Co., Ltd.—An extraordinary meeting was held on February 9, at which certain arrangements proposed by the directors relating to the development of the barium cyanide process of fixing atmospheric nitrogen were approved. The experimental work connected with this process has been done by the Oldbury C.S. Syndicate, an offshoot of British Cyanides Co., Ltd., and the main difficulty of obtaining the right kind of furnace is now believed to be overcome by a new furnace designed by Arthur Duckham and Co. An agreement between this company and the Syndicate is now to be signed which gives the latter, *inter alia*, an exclusive licence to use the patents taken out by Sir Arthur Duckham or his firm relating to furnaces used in the barium or similar processes, in return for a share interest in the Syndicate.

TRADE NOTES.

BRITISH.

Fiji in 1919.—The chief products of Fiji are sugar, copra, and bananas. Although the sugar industry was suffering from a lack of labour, due to the disorganisation of Indian immigration, the amount of sugar shipped was 64,348 tons, or 1278 t. more than in 1918. Additional areas of coconut trees are coming into bearing, and the export of copra will probably increase steadily; exports in 1918 and 1919 were 19,318 t. and 27,311 t., respectively. The increased export of rubber from 36¼ t. in 1918 to 69 t. in 1919 was due to some extent to shipments held over from the previous year; the rubber trees continue to give satisfactory results, large areas are available for cultivation at reasonable rentals, and the prospects of the industry are favourable.—(*Col. Rep.—Ann., No.* 1047, *Nov.*, 1920.)

Gambia in 1919.—In the colony of Gambia, which covers 4132 sq. miles, exist many deposits of iron ore, ochre, and china clay, but none of these is mined. The iron ore is situated most favourably for direct loading into ships, but is of poor quality. The staple industry is farming, the chief crop being groundnuts, in which there is a considerable export trade. As an area of 640,000 acres of suitable soil is available for this crop, there is scope for considerable expansion. The collection and export of wild rubber have practically ceased. Small amounts of cotton are grown, but the further development of this and of other commercial crops is severely limited by the scarcity of rain. The exports, valued at £1,553,521, included 70,270 tons of groundnuts and 671 t. of palm kernels; gum and wax have practically disappeared from the export list. Of the import trade, valued at £1,250,320, the United Kingdom supplied 57 per cent., and the United States 19 per cent. (4 per cent. in 1915).—(*Col. Rep.-Ann., No.* 1053, *Dec.*, 1920.)

FOREIGN.

Trade of the Belgian Congo.—The Belgian Congo has developed rapidly since it was opened to world trade, the mining industry shows increased returns every year, and agriculture is making good progress. Coffee and rice are now staple exports; cotton growing is promising well, the 1920 crop being estimated at 982 tons. The export trade in 1917, valued at £7,164,022, showed an increase of over 250 per cent. as compared with 1913, and comprised 3700 long tons of rubber, 38,487 t. of palm oil, and considerable quantities of palm-nuts, cocoa, copal, ivory, coffee, timber, and various minerals. The imports, valued at £2,767,239, were derived chiefly from the United Kingdom, South Africa and Rhodesia, followed by the United States and France, the share of Belgium being small owing to export restriction. Among the imports were:—Cement, 2699 t.; petroleum, gasoline, etc., 2696 t.; colours, dyes, and varnish, 240 t.; and soap, 584 t.—(*U.S. Com. Rep., Nov.* 4, 1920.)

Portuguese Trade in 1919.—Although the export trade in 1919 increased but slightly, the value of the imports more than doubled, owing to diminished production, the introduction of the 8-hour day, and the need for replenishing stocks. Business, generally, was prosperous, coal again became available, and the cork industry had a good season.

The imports, valued at £38,600,500 (escudo = 3s. 4d. at par), included:—Cement, 12,155 metric tons; sodium borate, 44 t.; sodium carbonate, 1289 t.; sodium sulphate, 280 t.; caustic alkali, 2423 t.; carbonate of calcium, 1233 t.; chlorate of calcium, 1038 t.; nitrate of potash, 142 t.; nitrate of soda, 218 t.; quinine salts, 70 t.; copper sulphate, 2043 t.; other chemicals and drugs, 4844 t.; coal, coke, etc., 609,363 t.; dyes and colours, 851 t.; dyeing extracts, 947 t.; dyewoods, 165 t.; fertilisers, 23,292 t.; oils and fats, animal, 1272 t.; palm oil, 1532 t.; other oils, 322 t.; perfumery, 74 t.; and sulphur, 6305 t. The greater part of the chemical imports is supplied by England.

Among the exports, the par value of which was £18,425,666, were:—Argols, 11,666 metric tons; chemical products, 1526 t.; cork and cork products, 71,223 t.; hides, 1612 t.; cod oil, 524 t.; mineral oil, 569 t.; olive oil, 720,360 litres; copper ore, 18,403 t.; iron ore, 7375; wolfram, 770 t.; other ores, 1101 t.; paper pulp, 858 t.; rosin, 1661 t.; turpentine, 370 t.; wax, raw, 112 t.; vinegar, 320,610 litres; glassware, 365 t.; and soap, 189 t.—(*U.S. Com. Rep., Nov. 3, 1920.*)

GOVERNMENT ORDERS AND NOTICES.

Prohibited Exports.—The following have been removed from lists "A" and "B" of prohibited exports as from February 1:—(1) Coal tar, all products and derivatives thereof, whether actually so obtained or so derived from other sources (including all mixtures and preparations containing such products and derivatives), suitable for use in the manufacture of dyes or explosives; (2) dyes and dyestuffs manufactured from coal-tar products and articles containing such dyes and dyestuffs; and (3) indigo, synthetic.

Yeast was removed from the same lists on January 13.

Decontrol of Coal.—The Directions of the Board of Trade, dated August 25, 1920, regarding pithead prices of coal, are to be cancelled as from March 1 next, as there is now no danger of shortage within the country, and the export price has approached the home price so closely that there is no longer any reason for restricting prices. Further, the directions for the supply of specified districts or consumers, will cease to have effect from the same date, and inland consumers will then be free to purchase from any source. The position as to the supply of coal for foreign bunkers and export remains as published in the *Journal of the Board of Trade* for December 28, 1920, and January 10, 1921.

Fire Prevention.—A Royal Commission has been appointed to inquire into the existing provision for the avoidance and extinction of fires.

Miners' Lamps Committee.—The Secretary for Mines has reappointed, with extended terms of reference, the Miners' Lamps Committee which was appointed by the Home Secretary in May, 1919. The Committee has to report upon possible improvements in the safety and illuminating power of miners' lamps, testing methods, maintenance of the lamps, use in mines which show no indication of inflammable noxious gases, etc. Mr. W. Walker, of the Mines Department, is chairman, and Prof. R. V. Wheeler is a member of the Committee.

REVIEWS.

Nucleic Acids: Their Chemical Properties an[d] Physiological Conduct. *By* Walter Jones. *Second edition. Pp.* viii. + 150. (*London: Longmans, Green and Co.* 1920.) *Price* 9s. *net.*

As the science of biochemistry advances the problem of the nature of the substances most intimately connected with the living cell—which constitute, as it were, the chemical basis of life—is being gradually unravelled and the substances themselves isolated and relegated to their proper position in chemical classification. Within comparatively recent years the sugars, the purines, the proteins, and the lipins have yielded many, though by no means all, of their secrets to the investigator, and some beginning has been made in the study of their functions in the living organism. In the present work an account is given of the elucidation of the chemical nature of another group of substances of great physiological interest—the nucleic acids. The fundamental importance of the nucleus in all the physiological relations of the cell has long been recognised by biologists and renders the story of the discovery of the chemical nature of the nuclear constituents, as told in the first half of Prof. Jones's book, one of intense interest and fascination. The nucleic acids occur in the cell nuclei combined either with proteins, as *a-nucleoproteins*, or with the much simpler protamines, in which form they are present, for example, in the spermatozoa of fish. The a-nucleoproteins consist most probably of various salts of protein with nucleic acid, in which the protein is in excess. When they are digested with pepsin part of the protein is digested away, leaving a mixture of more acid salts, indefinitely called *nuclein*. To use the term introduced by Kossel, the nucleic acids forming the prosthetic group of the a-nucleoproteins are nucleins.

Many chemists have contributed to the discovery of the constitution of the nucleic acids, prominent among whom are Kossel, Levene, and Jones, the author of the present work. So far as is known only two nucleic acids exist: that prepared from the cells of animals, generally known as thymus nucleic acid; and that obtained from vegetable cells, usually termed yeast nucleic acid. These two agree in their general structure but differ in the nature of their components and to some extent in their behaviour towards reagents. Yeast nucleic acid, the better known of the two, is resolved by mild alkaline hydrolysis into four groups, known as *nucleotides*, each of which is a compound of phosphoric acid, *d*-ribose and a base, probably combined in that order. Two of these bases are purines, guanine and adenine; the other two pyrimidines, cytosine and uracil. These nucleotides are themselves decomposed by further hydrolysis with loss of phosphoric acid and formation of *nucleosides*, each composed of *d*-ribose and the corresponding base:—

	Neucleotides.	*Nucleosides.*
Yeast nucleic acid →	Guanine nucleotide	→ Guanosine
	Adenine ,,	→ Adenosine
	Cytosine ,,	→ Cytidine
	Uracil ,,	→ Uridine

The exact mode of combination of the various components within the nucleotides and of the nucleotides with each other is not yet definitely settled.

Thymus nucleic acid is probably constituted after a similar plan, but the sugar group is a hexose, and the four bases are guanine, adenine, cytosine, and thymine.

The second part of the book is devoted to the no less fascinating story of the physiological conduc[t]

the nucleic acids, which affords an admirable mple of the remarkable complexity of chemical nges in the living organism as well as of the aordinarity specific adaptation of its enzymes he materials upon which they have to exert their on. Briefly put, nucleic acid is first decom-d into its constituent nucleotides by means of *ucleinase*, present in the intestinal juice. The leotides thus liberated may undergo decomposi-in either of two ways. First, by the action of a *pho-nuclease*, they may yield phosphoric acid the corresponding nucleoside. This is the only ge observed with the two pyrimidine nucleo-s, and the fate of the resulting pyrimidine eosides is not fully understood. The purine eotides, however, may also be acted on by a *ne-nuclease*, yielding a purine and a carbo-ate phosphoric ester. The purine nucleosides also be directly hydrolysed, by a *nucleosidase*, rine and carbohydrate. Here, however, a fur-complication arises, for the purine bases them-s and the purine nucleosides may be de-nised (by specific enzyme action), guanine yield-xanthine, and adenine, hypoxanthine, whilst the nucleosides undergo a similar change, forming nucleosides, which on hydrolysis (again by me action) yield xanthine and hypoxanthine. lly, oxidising enzymes come into play, and the xanthine passes first into xanthine and then uric acid. Here in man and the higher apes process stops and the uric acid is excreted, or in the system to cause those ills which are the lty of our evolutionary superiority. In the mammals, including the monkey, the uric acid most completely oxidised to allantoin, which is ted.

the biochemist this book cannot fail to be of und interest, alike for the importance of the er and the lucidity of the exposition. Appen-concerning practical methods and a biblio-hy of over five hundred papers add to its use-ss.

A. HARDEN.

ZWISCHENPRODUKTE DER TEERFARBENFABRIKA-TION. *By* OTTO LANGE. *Pp.* xxiv. + 645. *Leipzig: Otto Spamer.* 1920.) *Prices:—Un-bound, Germany,* 135 *marks plus* 40% ; *England nd Colonies,* 80*s.*

sely bound up with the vitally important em of developing our industry in fine icals, including the coal-tar intermediates, is uestion of the provision of a technical litera-of an informative character. Although the ction of such treatises is more prevalent now formerly in this country, English-speaking ists are still largely dependent on German ooks for the detailed information which is tial to a working specialist in any of the main hes of chemical technology.

appearance of the volume under review is f many evident signs that this hegemony in cal literature will not be easily surrendered, hatever developments the future may bring, n indisputable fact that the published records ogress achieved in coal-tar chemistry during st two or three decades are to be found largely rman patent specifications.

author introduces his subject by laying stress circumstances that the coal-tar intermediates tute the basis of the synthetic colour industry, he task he has set himself is to present within ate compass, in tabular form, an epitome of ery large group of chemical substances. The sions of the work may be gauged by noting his tabulation contains 3637 entries; but these sent a far greater number of compounds, for merous instances the entry is generic and con-references to many chemical entities. The se is in the first instance divided into four principal sections under the headings of benzene, naphthalene, anthracene, and phenanthrene, and in each of these sections the derivatives of the parent hydrocarbon are arranged in increasing order of complexity. The introduction and summary of contents furnish an explanation of the system of arrangement whereby it is easy to find the reference to any desired intermediate. Each reference contains a characteristic number by means of which the intermediate or group of intermediates can be located on looking up the comprehensive index. The patent is cited in which the given intermediate was first described, and this quotation is followed by a concise summary of the method of preparation.

In the vast majority of cases references are given only to German patents, but occasionally English, French, and American specifications are quoted, but only as subsidiary citations. In many instances this information is supplemented by references to German scientific journals. Providing that the reader has access to the principal German patents on coal-tar intermediates, such as those reproduced in Friedländer's comprehensive treatises on the progress of the coal-tar industry, then the problem of tracking down any particular intermediate will be greatly facilitated. From the number of entries it is obvious that a very large number of intermediates are tabulated, but at the same time many substances of purely scientific interest are omitted, since these can be found by reference to the lexicons of Richter or Stelzner. Considerable space is saved by omitting all names of authors or patentees. On the other hand, the parts by weight of the reagents, the physical constants (melting and boiling points) of the products, and other experimental details are indicated whenever these are likely to be of practical utility.

Cross references are furnished by the addition of lists of the German provisional and complete specifications (Anmeldungen and D.-R.P.P.), so that when a patent number is known the compound or compounds described in the specification can be identified.

The text is remarkably free from typographical errors and other inaccuracies, and the entire treatise is a simple guide to the more detailed information scattered through German patent literature.

G. T. MORGAN.

BENZOL: ITS RECOVERY, RECTIFICATION, AND USES. *By* S. E. WHITEHEAD. *With an introductory note by the* RT. HON. LORD MOULTON. *Pp.* xiv.+209. *(London: Benn Bros., Ltd.* 1920.) *Price* 12*s* 6*d net.*

Although the recovery of benzene and its homologues from the coal gas produced in coke ovens has been practised on the large scale for many years, the literature on the subject is very scattered and incomplete. The demand arising out of the war for the maximum production of benzene and toluene as the main raw material for high explosives, rendered necessary the equipment not only of all coke-oven installations with "benzol" plant, but also, as far as practicable, the adoption of the process in gas works; and in carrying out this work the want of a book dealing with the subject was seriously felt. This want still continues in spite of the decreased requirements for explosives, as the combined demand for these hydrocarbons in the organic chemical industry and as motor spirit is far in excess of the supply.

Mr. Whitehead's book is designed to fill the gap and to incorporate the results of the author's experience on the technical staff of the Department of Explosives Supply during the war, with a very large number of installations of "benzol" plant, varying from fully equipped large-scale plants to small emergency plants often constructed largely

the Journal form a fund of information in condensed form, but they are naturally of a somewhat disjointed character, and it is not easy for the reader to gather from them a connected account of what has been or is being done in branches of industry other than his own. For this reason the Annual Reports should prove an indispensable addition to the library of every chemist and manufacturer, and it is hoped that those who have realised their value will help in making their character more widely known among those who have not.

In the space available here it is impossible to give a complete account of the contents of the volume now in the press, but a few notes on some of the items dealt with may be of interest.

In the section on "Plant and Machinery," Dr. W. B. Davidson gives an account of the new electrostatic dust separator erected at Skinningrove. The subject of lubrication is also fully dealt with both in this section and in that on "Mineral Oils" (*cf.* i.). He also deals with the ever-important question of efficiency of combustion and fuel conservation, subjects which are also treated from their respective standpoints by Prof. J. W. Cobb and Mr. H. J. Hodsman in the section on "Fuel" and by Dr. G. Weyman in the section on "Gas and Carbonisation." In these two sections also the Gas Regulation Act receives due attention, whilst the reports indicate distinct, though slow progress in the elucidation of the chemical nature of coal and the mechanism of combustion, and the improvement of carbonisation. The work of the Nitrogen Products Committee, as revealed in its report published early last year, is alluded to in these and in several other sections of the volume, where it touches on the heavy chemical, electrochemical fertiliser and other industries. Dr. A. E. Dunstan, in the section on "Mineral Oils," discusses the conservation of oil resources and the best methods of utilising available supplies; he also deals, *inter alia*, with the conversion of paraffins into fatty acids (a topic also discussed by Mr. Allan), the manufacture of helium, and the progress of "colloidal" fuel.

In the section on "Colouring Matters and Dyes," by Mr. F. M. Rowe, there is an interesting account of the commercial development of the industry; in regard to technical progress perhaps the most interesting work of the year, from the standpoint of the general reader, is that dealing with photosensitising dyes—a subject which is naturally also considered fully in the photographic section. Mr. S. S. Napper records a notable improvement in the character of the work on "Fibres, Textiles, Cellulose, and Paper," especially as regards researches on the chemistry and constitution of cellulose and its derivatives, and on the chemistry and analysis of woods. In the section on "Bleaching, Dyeing, Printing, and Finishing," by Mr. B. Leech, considerable progress is recorded in such matters as the scouring of textiles and the production of Aniline Black.

The most important work of the year in the domain of "Acids, Alkalis, and Salts," dealt with by Dr. T. Ewan, relates to the synthesis of ammonia (with especial reference to the Claude process), the production of nitric acid and of cyanides.

Prof. W. E. S. Turner has much useful work on "Glass" to put on record, especially in regard to optical glass and the effect of varying composition on the properties of glass; it is gratifying to note that much of this work was done in this country. The same author deals with "Refractories," and in this and the section on "Ceramics," by Mr. W. C. Hancock, the predominance of the scientific work done in this country and in America is apparent.

Prof. J. H. Andrew, dealing with "Iron and Steel," remarks that these industries are rapidly becoming more scientific in character. Valuable work is recorded in regard to blast-furnace practice, special steels, etc., particular note being made of the Report of the Steel Research Committee on the subject of wrought automobile steels. Prof. C. H. Desch also has useful progress to record in "Metallurgy of the Non-Ferrous Metals"; in this report the flotation process and the metallurgy of zinc and tungsten occupy important places, and full consideration is given to the question of brasses and the theory of corrosion. Reporting on the "Electrochemical and Allied Industries," Mr. D. F. Campbell notes the depressing effects on these industries of the prevailing industrial and financial conditions; much of this section is devoted to iron, the electrical production of steel, and ferro-alloys, electrolytic zinc, and carbon electrodes.

Mr. John Allan comments on the lack of work on the general chemistry of "Oils, Fats, and Waxes." In addition to dealing with the oxidation of paraffins, he also has considerable progress to record on the chemistry of marine animal oils and drying oils, and on the important subject of fat-hardening. Drying oils are also dealt with by Mr. A. de Waele in the section on "Paints, Pigments, Varnishes, and Resins"; in these industries a large volume of work is evident, especially on the examination of pigments and varnish products. Dr. H. P. Stevens records considerable progress in work on the preparation of raw rubber (particularly that carried out in Java) and also on accelerators of vulcanisation, much of this latter being of British origin; the Peachey process of cold vulcanisation is also dealt with. In the section on "Leather and Glue" Mr. F. C. Thompson gives especial prominence to the work on analysis of tanning materials (with special reference to the question of "true tanning value"), the theory of tanning, and the chemistry of hide and gelatin—subjects on which much useful research has been published.

Dealing with "Soils and Fertilisers," Dr. E. J. Russell gives an interesting summary on the nitrogenous fertilisers and deals adequately with other sources of plant food; he also supplies a useful account of recent work on the determination of hydrogen-ion concentration and its significance in agriculture. Mr. J. P. Ogilvie, in the section on "Sugars, Starches, and Gums," traces the progress of the raw material (both cane and beet) through the various processes of sugar making, and deals with the improvements in extraction, clarification (including the use of decolorising carbons), and boiling to grain; the work carried out by the U.S. Bureau of Standards on the determination of sucrose by double polarisation is fully described. Messrs. A. Tait and L. Fletcher contribute the section on "Fermentation Industries," and have much work to record, including a number of papers on the chemistry of enzymes and the fermentation process, yeast, and power alcohol; the work on fermentation acetone is also noted and also that on vitamins in so far as it applies to the industries in question. This latter topic is fully discussed by Dr. H. W. Bywaters in the section on "Foods," and considerable progress in this direction is recorded; much useful work on bread and flour is also noted, and due consideration is given to the report of the Food Investigation Board. Dr. H. T. Calvert deals with "Sanitation and Water Purification," and gives an account of the steps being taken to prevent rivers pollution and the progress towards an understanding of the "activated sludge" process of sewage treatment.

In the section on "Fine Chemicals, Medicinal Substances, and Essential Oils" Dr. T. A. Henry gives instances of the great fall in prices of these products during the last few years. Among the topics with which he deals are the chemistry of cinchona and opium alkaloids, local anæsthetics, essential oils, and organic compounds of metals

(arsenic, antimony, mercury, silver). Mr. R. E. Crowther contributes the section on "Photographic Materials and Processes," and has considerable progress to record in work on the chemistry of development processes and the preparation of photographic emulsions sensitive to light of all colours; the allied subject of photo-sensitising dyes naturally finds a place here, and some important work on sensitometry is also described.

Mr. W. R. Rintoul has a large mass of work to report in "Explosives," both as regards high explosives for military and for civil purposes, and on the initiation of explosions. Much of the work carried out during the war on nitroglycerin and nitrocellulose has now become available and is duly noted. In conclusion, Mr. C. A. Mitchell has made a judicious selection of the more important literature on "Analytical Chemistry" as applied to technical work in those subjects in the reports of which it has not been dealt with.

The above brief notes may serve to give some idea of the vast amount of work covered by the reports. It will also indicate that there is a certain amount of duplication in the work discussed in the various sections. This is a desirable feature, since it presents important subjects from quite different standpoints—often from those of producer and user respectively—and so enables the reader to gain a more balanced view of the subject.

FEBRUARY MEETING OF COUNCIL.

The monthly meeting of the Council was held on February 11, Sir Wm. J. Pope presiding. Among other matters considered the following may be mentioned:—

It was reported that Monsieur Paul Kestner's paper which is to be read at a joint meeting of this Society and the Institution of Mechanical Engineers on March 4 will be printed in the *Proceedings* of the Institution, and that arrangements had been made for the Society to publish in the Journal as much of the paper and discussion as it considers desirable A supply of advance proofs of the paper will be available for distribution to any members of the Society who may wish to have a copy.

The Council agreed to make a grant of £100, as was done last year, to the Chemical Society towards the expenses of its Library scheme.

Owing to the considerations that a re-transfer of the Society's investments would entail expense, and that a trustee would be ineligible for election to the Council, it was resolved that the investments forming the Messel Fund should be held directly by the Society and not by trustees.

It was intimated that no essay had been received in competition for the Cross and Bevan Prize and the Latham Fellowship, and an alternative scheme was submitted by Mr. C. F. Cross, which was approved by the Council. Particulars of this will be published in due course.

Information was furnished regarding the sailings of steamships to Montreal in time for the Annual Meeting in the Autumn, full particulars of which appear on page 59 R of this issue.

Sixty-eight new members were elected, of whom [illegible] are home members, 2 colonial, 3 Indian, 9 in the United States, and 2 in other foreign countries.

Sir William Pearce, M.P., was elected the Society's representative on the Governing Board of the Imperial College of Science and Technology, in succession to Dr. C. C. Carpenter, resigned.

The Secretary laid on the table the original register of the Society, which had been discovered during some alterations in the premises of the United Alkali Co., Ltd., Widnes.

NEWS FROM THE SECTIONS.

BIRMINGHAM.

A meeting was held in the University Buildings on January 27, with Dr. H. W. Brownsdon in the chair. Messrs. E. C. Rossiter and P. H. Sanders presented a paper on "The Preparation of Zirconia from Brazilian Ore and a New Method of Determination," in which they described a process for preparing zirconia of 98—99 per cent. purity by fusing the ore with its own weight of caustic soda at a maximum temperature of 600° C., and then proceeding as follows:—The melt is lixiviated with water, washed, and the residue evaporated to dryness with hydrochloric acid. It is then extracted with water and filtered, when 80 per cent. of the zirconia is obtained in solution. The dilute solution is heated with sulphurous acid to reduce the iron salts, and then the addition of dilute sulphuric acid effects a quantitative precipitation of a basic zirconium sulphate having the composition $5ZrO_2.2SO_3.xH_2O$. This is washed by decantation, filtered, dried, and converted into zirconia by ignition. The conditions under which the precipitation of the basic zirconium sulphate is quantitative were given.

On February 10, Capt. B. J. Eaton gave a lecture on "Plantation Para Rubber" to a joint meeting of the Section and the Birmingham University Chemical Society.

The lecturer opened with some statistical information, stating, *inter alia*, that of the 350,000 tons of Hevea rubber now produced annually, about one-half comes from British Malaya (where the planted area is about 1½ million acres), one-quarter from Ceylon, Southern India and Burma, and almost all the remainder from the Dutch East Indies; about 75 per cent. of the world's output is supplied by the British Empire. The production of fine hard Para rubber from the wild Hevea in South America remains stationary at about 30,000 t. per annum, but African and other wild rubbers have practically disappeared from the market. The rest of the lecture dealt with the collection and coagulation of the latex and with chemical problems connected with the preparation of the raw material and the influence of method of preparation and other factors upon the raw product during vulcanisation. At the present time acetic acid is almost exclusively used as coagulant, although, owing to its high cost, it was to some extent replaced by sulphuric acid during the war; but mineral acids are in general unsuitable owing to their influence on the raw rubber during vulcanisation. The use of alum for this purpose in Malaya has been prohibited by legislation. After describing the preparation of smoked and unsmoked sheet and of pale crêpe, and indicating how the mode of preparation influenced the speed of vulcanisation, Mr. Eaton described briefly the work which had been done in the laboratories of the F.M.S. Department of Agriculture, showing how the cause of this variation in speed had been elucidated and how it could be overcome. Finally, in referring to variability in tensile properties, he stated that there was evidence that inferior tensile strength was in some cases due to intrinsic differences in the raw product, *i.e.*, in the caoutchouc, not in the mode of preparation.

BRISTOL AND SOUTH WALES.

At an ordinary meeting held at University College, Cardiff, on February 4, Prof. C. M. Thompson presiding, a paper was read by Dr. R. W. Atkinson on "The Iron Ores of South Wales."

After referring briefly to the ironstones of the coal measures, the author proceeded to describe the chief occurrences of iron ore in South Wales. The so-called limonite deposit extends from Rudry to Bridgend and probably further, as there is evidence

of the mineral as far west as Mumbles. The ore occurs between a dolomitic conglomerate and underlying carboniferous limestone; the angle of dip is 32° N., frequently following cracks and joints in the strata. Although ore was formerly raised in large quantities from Trecastle Mwyndy, Garth, and Llanharry, to-day the only mine working is that of Llanharry. Analyses show that the preponderating mineral is not limonite, but göthite ($Fe_2O_3.H_2O$), the observed ratio of Fe_2O_3 to H_2O being very nearly 1:1. Some of the ore very closely resembles the well-known Cumberland kidney-ore in appearance and is also found to be göthite. Regarding the origin of these deposits, the author expressed the view that the replacement followed the entrance of the iron from above and not from below, as has been thought by some. Experiment shows a marked difference in bulk between the freshly precipitated oxide and the mineral of lesser hydration.

NOTTINGHAM.

At a meeting held on February 16, Mr. J. H. Dunford presiding, Sir William Pope gave an address on the scientific aspects of colour photography (*cf.* J., 1920, 369 R), at the close of which Mr. H. D. Richmond described his early experiments on the same subject.

FATS AND FATTY ACIDS FROM HYDROCARBONS

Synthetic fatty acids.—Methods for producing fatty acids may be broadly classified into two main groups, in the first of which the fatty acids are built up from hydrocarbons of low molecular weight, such as ethylene or acetylene, or are truly synthesised from hydrocarbons of high molecular weight by means of known reactions. In the second class a hydrocarbon of a higher molecular weight than that of the fatty acid required is submitted simultaneously to partial degradation and oxidation. In this class paraffin wax or high-boiling natural hydrocarbons are obviously available as raw materials.

Synthesis from compounds of low molecular weight.—It is not the writer's purpose to describe fully the various methods by which fatty acids have been built up from such substances as ethylene or acetylene. It will be sufficient to indicate the methods of Harries and Willstäter, who propose to synthesise glycerol, and by polymerisation and oxidation to convert it into such acids as oleic acid. When it is considered that ethylene or acetylene is to be converted into formaldehyde or ethyl alcohol, and glycerol obtained from the latter, it will be obvious that the number and complexity of the reactions involved are incompatible with technical and competitive production. The failure of the synthetic-alcohol process in Switzerland—by which calcium carbide was treated to produce acetylene, acetaldehyde produced from the latter by catalytic hydration in the presence of mercuric salts in acid solution, and ethyl alcohol obtained by the hydrogenation of the acetaldehyde in the presence of reduced nickel as catalyst—is distinctly significant in this connexion, for cheap electrical power for the manufacture of calcium carbide and for the production of electrolytic hydrogen, is available in Switzerland, and alcohol prices seem to have been sufficiently high of late to render the prospects of such a synthetic process more than usually favourable.

Further, by assuming an impossibility, namely, that all the complex reactions could be carried out at almost 100 per cent. efficiency, it is clear that, as all the carbon of the resulting fatty acid must come from the original ethylene or acetylene, a ton of fatty acid could not be produced from less than about a ton of hydrocarbon gas. The production of a ton of the comparatively cheap acetylene necessitates the usage of about four tons of 80 per cent. calcium carbide. Bearing this figure in mind, and making allowances for losses in processes, working expenses, chemicals, power and labour, it is scarcely necessary to elaborate any destructive criticism of processes which use the available low-molecular-weight compounds as starting material for the synthesis of fatty acids.

The Zelinsky Process.—The Zelinsky process, by which a paraffin hydrocarbon is chlorinated in the α-position, a magnesium-alkyl chloride made, carbon dioxide passed in, and the resulting compound acidified to liberate the fatty acid corresponding to the original paraffin, is extremely interesting theoretically, and represents as skilful a piece of work as any of the German synthetic processes. It fails absolutely when subjected to the test of practical applicability, although it is rumoured that the United Chemical Works of Charlottenburg carried it out successfully during the later years of the war. There are, however, several theoretical objections to this process, apart from the cost in metallic magnesium (about 10 per cent. of the weight of fatty acid produced being required) and the cost of chlorine for the original chlorination—the hydrochloric acid produced being used in the final acidification of the "Grignard" carbon-dioxide addition product. In the first place, a satisfactory and determinate chlorination of even an extremely carefully fractionated "cut" of petroleum is apparently impossible. It has been shown by Mabery (J. Amer. Chem. Soc., 28, 165) that a monochloride having the chlorine atom in the α-position is extremely difficult to prepare.

Again, assuming that a suitable chlorine derivative or derivatives of one or more hydrocarbons of desirable molecular weight could be obtained, the formation of the magnesium-alkyl chloride is not easy. Anyone familiar with the Grignard reaction knows the difficulty of preparing magnesium-alkyl halides from halogen derivatives of hydrocarbons of even moderately high molecular weight. A suitable solvent has still to be discovered in which to carry out the reaction with compounds prepared from high-boiling hydrocarbons. Moreover, the magnesium-alkyl halides of high molecular weight do not react in the same simple direct way as those of lower molecular weight. There is always a tendency to react with the alkyl chloride, with the ultimate production of condensation products of complex hydrocarbons.

On the whole, therefore, it is exceedingly difficult to see how such a complex series of reactions can be carried out on a commercial scale. Zelinsky, it is true, states that satisfactory yields of an acid, $C_{11}H_{22}O_2$ were obtained when a hydrocarbon mixture boiling between 132° and 144° C. was used as starting material, but the results have not been substantiated on a technical scale, and yields would undoubtedly be still lower when higher hydrocarbons were employed with the intention of obtaining acids of the order of stearic and oleic.

There can be no doubt that the Zelinsky process is uneconomical for practical purposes at present.

The oxidation of hydrocarbons.—The higher hydrocarbons which occur in the natural petroleums and in the products of destructive distillation of coal, lignite, shale, etc., provide a very attractive and comparatively cheap starting material for the production of fatty acids by oxidation processes. Both paraffins and olefines have been utilised in the suggested processes, and in many instances a relatively expensive paraffin wax has been employed. It is clear, however, that a process, successful when the fairly simple mixture of hydro-

carbons contained in paraffin wax is used as starting material, would not necessarily be applicable to the many varieties of natural petroleums, and this fact should be borne in mind when such apparently satisfactory results as are quoted by Grün (*cf. i.*) are being considered.

The Harries process, in which the high unsaturated hydrocarbons are treated with ozone, the resulting ozonides decomposed by steam into peroxides, and the latter transformed into alkali salts of the higher fatty acids by treatment with caustic alkali solutions, requires little consideration here, although large scale trials have been made. The constitution of natural hydrocarbons, or of those obtained by destructive distillation processes, is by no means clear, but we are sufficiently familiar with its general outlines to know that the formation of an ozonide mixture in appreciable quantity from such oils is scarcely possible. Indeed, Harries states that only 0·12 tons of fatty acids can be produced from the olefines contained in the oils resulting from the destructive distillation of 100 tons of lignite.

The power charges for the production of the necessary amount of ozone are far too high to enable a process dependent primarily upon ozone to be economically feasible when the end product is a fatty acid, and not a "fine" chemical. We may here contrast the production of vanillin from iso-eugenol by means of an oxidation process depending upon the use of ozone. In this case the value of the product allows of a relatively expensive oxidising agent being used, especially as much higher yields result than are obtained by the employment of such oxidising mixtures as potassium bichromate and sulphuric acid.

The direct oxidation of a hydrocarbon mixture, *e.g.*, paraffin wax or a petroleum distillate, by means of atmospheric oxygen offers an attractive solution of the problem of the production of fatty acids. Intense interest has been concentrated upon this question in Germany, and this has led to many superficial attempts to solve the problem by "hit or miss" experimentation. It is true that results have been quoted which appear to be satisfactory, and, within certain limits, the production of fatty acids seems to have been achieved. The names of Franck, Farien, Kelber, Fischer and Schneider, and Löffl come into mind in this connexion. But one general criticism is suggested here. The results are, as a whole, far too indeterminate, and give little feeling of scientific confidence. We have the so-called influences of this and that catalyst described. We have the effect of pressure and temperature upon the formation of fatty acids discussed, but little valid experimentation is given as backing. We have yields quoted which should assure the commercial success of the processes, and yet fatty acids are not being manufactured. Finally, most of the oxidation experiments were carried out with a high-class paraffin wax as starting material. The hydrocarbons of the latter, under the influence of temperature, pressure and catalyst and with the passage of a current of air, are pyrolytically decomposed and presumably oxidised at the double bond formed on the "splitting" or "cracking" of the hydrocarbons. Even in this case, as is to be expected, a large variety of acids is produced, and this from a fairly simple mixture of hydrocarbons. The difficulty of applying the reaction generally without extensive research upon the various natural oil mixtures is apparent.

Some of the more reliable results, however, indicate a very promising outlook for this process, since the raw materials are cheap, abundant, and available, and the working expenses not, *primâ facie*, excessive.

It is known, of course, that the D. Fanto works at Pardubitz have been manufacturing an oxidation product of paraffin wax for some time, and have been obtaining a mixture of fatty acids which are said to be technically useful. The Franck process, moreover, in which paraffin is oxidised under pressure and in the presence of a catalyst consisting of a resinate of vanadium, manganese, etc., claims to obtain a yield of 85 per cent. of fatty acids, and a net yield of 70—75 per cent. of higher acids suitable for soap-making, esterification to produce fats, and for other purposes.

The results of many researches which have been communicated to scientific societies, especially in Germany, have been exceedingly contradictory, agreeing in practically one thing only, namely, the excellence of the yield of valuable fatty acids.

It is perhaps significant, too, that when the less highly-refined mixture of hydrocarbons resulting from paraffin-wax pressing was employed in place of paraffin wax itself, much poorer yields were obtained in at least one instance.

It is clear from even a cursory examination of the available literature on the subject of the oxidation of hydrocarbons to fatty acids that a great deal of fundamental knowledge is lacking, and that comprehensive researches must be initiated if success is to be attained.

The work of Grün, Ulbrich and Wirth (Ber., 53, 1920, pp. 987—996) appears to afford a striking contrast in many respects to that of several other investigators. It is claimed that the divergent results quoted by different observers are due, in many cases, to the lack of sufficiently accurate analytical control. It is, moreover, preferable to effect a less complete transformation of the original hydrocarbon in order to obtain larger yields of the higher fatty acids. An almost complete conversion often leads to excessive breakdown of the hydrocarbon chain, one carbon atom after another being oxidised away, with the production of lower fatty acids, soluble in water, and technically not so valuable as those of higher molecular weight. It is pointed out that the oxidation can be effected not only with oxygen and air, but also with a gas mixture containing as little as 1 per cent. of oxygen; and under mild conditions of oxidation, and with this 1 per cent. oxygen mixture, only 5 per cent. of water-soluble fatty acids was obtained, whilst simultaneously 50 per cent. of higher, water-insoluble fatty acids was produced. Again, under otherwise suitable conditions, the presence of many so-called catalysts is superfluous—as Löffl has also pointed out—and sometimes actually harmful.

When pure oxygen is used, the reaction is frequently so vigorous as to cause explosions, due to the rapid decomposition of substances of a peroxide nature. In a "normal" oxidation only small quantities of these peroxide substances are produced, and are immediately decomposed with no untoward results.

These observers noticed for the first time the production of waxes, which result from the esterification of the higher fatty acids with the higher alcohols formed as intermediate products in the oxidation. The complex reaction product contains, in addition to saturated fatty acids, quantities of hydroxy acids, and of unsaturated fatty acids formed from the latter by dehydration. The unsaponifiable residue contains only a little unchanged hydrocarbon, and consists chiefly of alcohols and ketones. In addition to taking extensive precautions with regard to analytical control and to reproduction of results in "repeat" experiments carried out under similar conditions, these observers have studied the oxidation of a pure hydrocarbon, namely, pentatriacontane, which is surely a move in the right direction.

Problems awaiting solution.—It is essential that a complete survey of the chemistry of the higher paraffins and olefines be made. Very definite information as to the occurrence of particular hydro-

carbons in different fractions of mineral oils is lacking, and must be obtained if we are successfully to oxidise them to fatty acids of definite composition and value. Methods of characterising the various mineral oils which are to serve as raw materials for this purpose must be available; and apparatus must be designed for obtaining any particular component or a definite mixture of components from natural oils on a practical scale.

With the chemistry of mineral oils established on a sound basis, it will be possible to turn with better prospects of success to the subject of the oxidation of a suitable fraction of a natural oil. More systematic atacks can then be made upon the problem of the influence of the various factors upon the oxidation, *e.g.*, the presence of a suitable catalyst, or of no catalyst at all, the presence of some alkaline agent to combine with and remove from the sphere of reaction the fatty acids produced, the effect of impurities, temperature, pressure, and so forth. Again, if known hydrocarbons can be isolated from mineral oils, experiments can be commenced upon the individual treatment required by the different classes of hydrocarbons. For instance, a hydrocarbon with about eighteen carbon atoms in its chain, but with an olefine linkage in the α-position, would possibly require different oxidation treatment from that applied to a similar hydrocarbon in which the double linkage was in the middle of the chain, and, of course, in the latter case widely different products would result.

The study of the chlorination products of the saturated hydrocarbons should be made in greater detail even than has been done by Mabery (*loc. cit.*), and with the extremely difficult question of α-chlorination settled, attention could be turned to the elimination of hydrochloric acid, and the formation of a double bond at the end of the hydrocarbon chain. Systematic research upon the problem of the oxidation of such a definite compound would then be possible, and would be much more satisfactory than investigations upon a complex mixture of unknown composition.

If, too, definite chloro-derivatives could be produced, one of the obstacles would be removed from the path of the Zelinsky process, although, in this process, the difficult problems of the starting, control and direction of the Grignard reaction, and the discovery of a suitable solvent would still remain.

These problems are, however, well in the future. Until the complicated mixtures of hydrocarbons of many different series which exist in the natural petroleums have been studied in great and almost wearisome detail, that is, until we know what we are working upon, and can separate different compounds which react specifically, we shall not solve the problem of the production of fatty acids, unless we do so by chance.

Synthetic fats.—Assuming that fatty acids could be produced in good yield, and sufficiently cheaply, by a process similar to one of those indicated above, the question of the formation of esters, glycerides or anhydrides suitable for edible purposes still remains. This should not be too difficult a matter. In the later years of the war 70—80 tons of "ester oil" per month was produced in Germany by the esterification of fatty acids (not synthetic) by means of ethyl alcohol or glycol.

Nevertheless, there are many problems of great importance connected with this question of synthetic fats. The various glycerides which constitute natural fats are many in number, and occur in a large variety of mixtures. To simulate a natural fat, with its mixtures of simple and mixed glycerides, would be no easy task, and the physiological study of compounded synthetic fats would have to be undertaken if such fats are to compete with natural fats in open market, and not merely to be supplied as prisoners' rations, or doled out to a starving population in blended margarines.

In the event of the fats obtained by the use of glycol or of mono- or poly-hydroxyl alcohols not being satisfactory, the esterification of synthetic fatty acids with glycerin would produce the analogues of natural glycerides. In this case, an opening would be provided for the development on an economic footing of the "Protol" glycerin process, in which suitable sugar-containing solutions are fermented under special conditions of alkalinity to produce glycerin, with alcohol, acetaldehyde, etc., as by-products.

Research would also be stimulated in the direction of using poly-hydroxyl alcohols, such as carbohydrates, for the esterification of synthetic fatty acids, and "fats" akin to the mannitan di-oleate, recently prepared by Lapworth, would result. Mannitan di-oleate was, of course, not produced by direct esterification, but there is no doubt that such an esterification is possible, and that the production of a fat of approved physiological value can be successfully accomplished.

Natural fats.—The problem of rendering petroleum available as a source of human energy by producing synthetic fats is therefore one which will only be solved after a very large amount of intensive and exhaustive research has been successfully undertaken. In passing, however, it is suggested that a more studied consideration of possible developments in natural vegetable-oil production would remove all fear of competition at the hands of the synthetic chemist. With careful selection of species, and systematic experiments in the production and application of suitable fertilisers, and with all the arts of the quickly-growing science of arboriculture, it should be possible greatly to increase the yield of oil per acre of ground cultivated. The fact that a similar study in the sphere of natural indigo has enabled the latter to compete with the synthetic product, so long its master economically, is significant in this connexion.

The production on a technical scale of fatty acids from petroleum hydrocarbons would appear to be possible, if remote; and were a successful process discovered, its general application would have but little effect upon the available supplies of mineral oil. Although the latter may be within measurable distance of exhaustion, the production of the million tons or so of edible oils and technically useful glycerides and fatty acids which are annually required in England would absorb such a small proportion of the hydrocarbon oil needed for other purposes that it would not become an important factor in petroleum economics. In August, 1920, the production of crude oil in America was about six million tons, and the consumption about seven million tons.

THE EFFECT OF ALKALINITY ON THE USE OF HYPOCHLORITES.

E. K. RIDEAL AND U. R. EVANS.

It is, of course, well known that hypochlorites are used very largely for the following purposes:—(1) Bleaching; (2) sterilisation of drinking water; (3) treatment of water for "textile finishing," to prevent growth of algæ and consequent stains; (4) addition to water of swimming baths; and (5) chloride of lime is employed freely as a deodoriser for household use, for the cleansing of drains, and, to some extent, as a disinfectant.

In the first case (bleaching), where the rapid oxidation of colouring matter is desired, *e.g.*, for wood pulp, it is a common practice to allow the hypochlorite to act in presence of acid; the bleaching is

then very rapid. But in most other cases it is customary to apply small quantities of hypochlorite to the fluid to be treated, quite irrespective or whether the fluid be acid, neutral, or alkaline.

Now, in general, oxidising agents act most powerfully in the presence of acids. This is readily observed in the case of typical oxidising agents such as permanganates, dichromates, and perchlorates, which all tend to render the solution of the substance acted upon less acidic or more basic than it was before. In electro-chemical language this fact can be expressed by the statement that the oxidation potential of the agent is raised by an increase in the hydrogen-ion concentration.

The effect of acidity on the oxidising power of hypochlorite solutions is particularly marked, probably because, as has been suggested by one of us,* hypochlorous acid is the effective oxidiser, the oxidising power of the salts and of the anion, $(OCl)'$, being but feeble.

Whether this explanation be accepted or not, the facts cannot be doubted. The matter is expressed quantitatively by the following data from the oxidation potential series† :—

Potassium permanganate..	..	$E_H = +1{\cdot}48$ volts.
Chlorine in acid solution ..	..	$E_H = +1{\cdot}39$,,
Chromic acid	..	$E_H = +1{\cdot}12$,,
Ferric chloride	..	$E_H = +0{\cdot}96$,,
Chlorine in alkaline solution	..	$E_H = +0{\cdot}86$,,

The table given indicates that chlorine in acid solution is nearly as powerful an oxidiser as potassium permanganate, and more powerful than chromic acid, whilst chlorine in alkaline solution (*i.e.*, hypochlorites) is less powerful than ferric chloride, which is far from being a vigorous oxidising agent.

It is not generally known, however, that a comparatively small change in the hydrion content of a water will produce a very marked change in the oxidising activity of the hypochlorite added. We have become very impressed with this fact in studying the dosage of different waters with hypochlorites by means of the electrical apparatus described by us some years ago.‡ We find that two waters, one an "acid" water containing free carbon dioxide and the other an "alkaline" water, such as occurs in the London basin, dosed with hypochlorite so that they contain the same amount of "available chlorine" (as measured by the ordinary iodometric method with titration in presence of acetic acid), give quite different results when allowed to flow through the electrical instrument. The acid water gives a large deflection, indicating high oxidising activity; the alkaline water gives a much smaller deflection, indicating that the oxidation potential has been depressed.

It is interesting to note that the dissociation constants of hypochlorous and carbonic acids and water have the following values:—

Hypochlorous acid	..	$K = 3{\cdot}7 \times 10^{-8}$	at 17° C.
Carbonic acid ..	..	$K = 3{\cdot}0 \times 10^{-7}$	at 18° C.
Water	..	$K = 0{\cdot}7 \times 10^{-14}$	at 18° C.

Consequently, if sodium hypochlorite be added to water containing free carbonic acid, sodium carbonate and free hypochlorous acid will result; but in water in which the hydrogen-ion concentration is less than in hypochlorous acid, only a small amount of the oxidiser will be present in this active form.

Since the germicidal properties of the substance are in part due to its oxidising power, it seems likely that these also will be affected by the hydrogen-ion concentration of the water. It would be worth while, therefore, to consider whether, if alkaline waters have to be treated with this class of steriliser, they should not at the same time be rendered just acid to litmus, or at least neutral, by the addition of nitre cake, aluminium sulphate, or even by treatment with carbon dioxide gas.

But there is another equally important point. Most hypochlorite liquors, whether made on the spot by treating bleaching powder with water, or brought from the factory as sodium hypochlorite solution, have an alkaline reaction. Just because they react less readily in alkaline solution, hypochlorites "keep" better in the presence of alkali, and the manufacturers are scarcely to be blamed if their products leave the works with more than a trace of alkali. But users should remember this fact, and neutralise the alkalinity of the solution before using it to treat contaminated water.

It is worthy of mention that some of the chloride of lime sold at small oil-shops and by grocers is largely decomposed before it reaches the user. Now the decomposition may proceed in various ways, but some at least of these cause the bleaching powder to become more alkaline as it decomposes. Supposing, therefore, that the bleaching powder has lost half its "available chlorine" (as measured iodometrically) by the time it reaches the consumer, it is not even true to say that the unfortunate user can make up for the loss in transit by employing a double quantity, since the extra alkali present has a depressing effect upon the oxidising properties of the substance remaining.

The variable character of the chloride of lime—as it reaches the consumer—appears to have very considerable public importance. One sample of chloride of lime (packed in paper), purchased by one of us at a local store, was found to contain only traces of available chlorine. Presumably the average user of the substance is not a chemist, and does not know that he is buying a valueless article. One cannot but conclude that, assuming the domestic use of chloride of lime by the customers of these stores to be necessary at all, they are running serious risks, since the safeguards which they imagine that they are taking are illusory. This is a matter to which public analysts would do well to pay serious attention. It is useless to blame the shopkeeper if manufacturers supply the substance in paper cartons permeable to carbon dioxide.

The strength of chloride of lime as it reaches the consumer in tropical countries has recently been discussed in this *Journal*.* It is, however, remarkable how little the unstable character of chloride of lime—even at low temperatures—is appreciated. It decomposes very speedily if exposed to damp air or to carbon dioxide. On the other hand, sodium hypochlorite solution of a good brand has proved, in our experience, much more satisfactory as a source of hypochlorite so long as it is kept in a cool place, protected from light, and tightly sealed to exclude carbon dioxide.

In view, however, of the difficulty of preserving hypochlorites, it is worth considering whether liquid chlorine could not usefully be employed for many purposes where hypochlorites are now used. As long as it is in cylinder, chlorine cannot decompose, and when dissolved in water the main primary reaction is believed to be:—$Cl_2 + H_2O = HCl + HClO$. Both of the substances produced are acid, and one is a strong oxidising agent.

Summary.—The oxidising power of hypochlorite solutions is greatly depressed by the presence of alkali. This fact should be borne in mind when it is proposed to use hypochlorites for treating alkaline waters; and the simultaneous addition of nitre cake is suggested.

Where alkali has been added as a stabiliser to commercial hypochlorite solutions, it may be advis-

able to neutralise before using the liquor for dosage. The instability of chloride of lime, and the poor quality of many of the samples supplied in paper packages by small stores, are matters of importance.

MEETINGS OF OTHER SOCIETIES.

ROYAL PHOTOGRAPHIC SOCIETY.

At the meeting held on February 8, arranged by the Scientific and Technical Group, Mr. T. Thorne Baker read a paper, by himself and Dr. M. Levy, on "High-Speed Radiography." A short statement on the present possibilities and requirements in X-ray work, with special reference to the use of calcium tungstate intensifying screens, led to a description of the new rapid X-ray plate. This is a double-coated plate, the lower film being light-sensitive, the upper one containing fluorescent calcium tungstate. As it is necessary to remove the top film before development, the lower film is specially hardened to stand prolonged soaking at 110° F., and a soft gelatin, dissolving easily in water at 95° to 105° F., is used for the upper film. The calcium tungstate is fired at a special temperature to obtain maximum fluorescence. The grains are sifted and only those between certain limits of size are used; smaller grains give less intense fluorescence and larger grains tend to make the image granular. The coating of the upper film is so arranged that the calcium tungstate settles to the bottom of film into close contact with the emulsion surface; this ensures maximum effect of the light emitted and enables the use of a much smaller quantity of calcium tungstate than is needed for an intensifying screen. The reduction of exposure required by this plate in comparison with an ordinary X-ray plate depends upon several factors and varies from 1/10" to 1/25"; better results are obtained with a hard tube than with a soft one. It was suggested that the new plate would be particularly useful in radio-metallurgy.

Mr. F. F. Renwick gave a short abstract of a paper received from Mr. Raymond Davis, of the U.S. Bureau of Standards. The multiplying factors of photographic light-filters are obtained by an apparatus comprising a movable lamp and a series of mirrors permitting the illumination of two adjacent portions of a photographic plate by lights of known relative intensities. A series of exposures is made with the filter in one path, the results plotted, and the position of equality determined from the curve obtained.

Mr. F. C. Toy, of the British Photographic Research Association, described a monochromatic illuminator designed chiefly for use with a mercury arc lamp. This is a simple device enabling the separation of any two bands of a spectrum, and the variation of the lengths of the two bands used can be adjusted to equal intensities by the aid of a thermopile and galvanometer. Known variation in relative luminosities of the two beams is then obtained by varying the distances of the recombining lens and the plate which receives the recombined image.

THE PHYSICAL SOCIETY.

The annual general meeting was held at the Imperial College on February 11, and after reports had been presented and officers elected, etc., a discussion was held on "Absolute measurements of electrical resistance and instruments based on the temperature-variation of resistance."

Sir Richard Glazebrook traced the historical development of absolute measurements of electric resistance, and Prof. Callendar dealt with the compensated resistance bridge and instruments for the measurement of radiation. Among the thirteen other papers read, mention may be made of the following as having some application in chemical industry. These papers illustrated the diversity of ways in which one of the fundamental devices of electrical measurement—the Wheatstone bridge—has recently been applied in the measurement of various physical quantities.

A liquid depth-gauge, enabling a reading of the depth of liquid in a vessel to be made at any distance from the vessel, was described by Mr. E. A. Griffiths. The instrument consists essentially of a Wheatstone network of four conductors, two of which, in opposite arms of the bridge, are wires of the same material, extending to the depth of the vessel. One of the wires is completely surrounded by a sheath to protect it from contact with the liquid. The other is similarly surrounded, but the sheath is provided with holes near the bottom and top, so that the wire is in contact with the liquid over a length equal to the depth of liquid in the vessel. The wires are heated by the current in the bridge and the original balanced condition of the bridge when the vessel is empty, is disturbed to an extent dependent upon the depth to which the one wire is in contact with the liquid. Constancy of current in the bridge is maintained by the use of a ballast resistance of iron wires enclosed in an evacuated space. The galvanometer employed is graduated so that its deflections indicate directly the depth of liquid in the vessel. The whole device is made up in a compact form, the indications are independent of temperature, and can be transmitted to any distance.

A strong and portable form of hot-wire anemometer was exhibited and described by Mr. J. T. McG. Morris. The Wheatstone bridge employed is composed of four nickel wires, alternate arms being shielded. When the device is exposed to an air stream the initial balanced condition of the bridge is upset owing to the cooling effect of the stream on the exposed wires, and the galvanometer deflections, after suitable calibration, indicate the velocity of the air stream in which the instrument is immersed. This device has been used to investigate the ventilation of mines, and should be applicable wherever measurements of air velocity are required (*e.g.*, air supply to producers, power plant, etc.), its indications being much more easily read than those of the Pitot tube. A form of hot-wire anemometer enabling the velocity of a slow-moving stream of gas to be determined, both as regards magnitude and direction of flow, was exhibited and described by Dr. J. S. G. Thomas (*cf.* J., 1920, 109 R). A combined form of instrument of the anemometer type, in which the exposed wire functioned first as a thermometer and then as the exposed wire of a hot-wire anemometer was described by Mr. A. H. Davis. The indications of such a device enable the heat loss by convection from heated bodies to be accurately determined. It has been used in investigating the thermal efficiency of various systems of cold storage.

Dr. G. A. Shakspear exhibited and described his gas permeameter, which contains a bridge-device of four fine wires similar to that mentioned above. Owing to the varying thermal conductivities of different gases, the heated condition of appropriate wires is dependent upon the composition of the gas in which they are immersed. After suitable calibration of the instrument, the galvanometer deflections indicate the percentage amount of any one constituent of the mixture present. Hydrogen is pre-eminent among gases for its extremely high thermal conductivity (hence the cold sensation experienced on plunging the hand into the gas), and the author's device has been extensively used to determine the purity of the hydrogen supplied for aeronautical purposes in the investigation of the

permeability of balloon fabrics, etc. A modification of the permeameter, in which the indicating instrument is suitably calibrated, constitutes the CO_2-recorder described and illustrated by Dr. H. A. Daynes. Prof. L. Hill exhibited the "caleometer," a bridge device enabling a record to be obtained of the state of the atmosphere as affording comfort or otherwise.

The familiar hair type of hygrometer has been modified by Dr. E. Griffiths so that its indications may be transmitted to a distance. The length of the hair employed is dependent upon the hygrometric state of the atmosphere, and the changes of length accompanying change of hygrometric state are transmitted mechanically to a pointer which makes contact with a long length of wire, the point of contact varying with the length of the hair. The two portions of the wire, one on either side of the point of contact, constitute two adjacent arms of a Wheatstone bridge, and it is evident that the indications of the galvanometer device employed will serve, after suitable calibration, to indicate the hygrometric state of the atmosphere surrounding the hair.

THE CHEMICAL SOCIETY.

At the ordinary scientific meeting held on February 17, ninety-seven new Fellows were elected, and Sir J. J. Dobbie, retiring president, made the following announcements:—

The Longstaffe Medal has been awarded to Prof. J. F. Thorpe. On the evening of the Annual General Meeting, March 17, the Anniversary Dinner will be held at the Hotel Cecil, Strand, W.C., at 7 p.m., to which the past-presidents who have attained their jubilee as Fellows of the Society will be invited as guests of honour. Applications for tickets (14s., exclusive of wine) should be made to the Assistant Secretary, at Burlington House, by March 10, and the presence of ladies as guests will be welcomed. The Council has decided to publish the list of physico-chemical symbols drawn up by the International Association of Chemical Societies.

Mr. L. J. Hudleston and Prof. H. Bassett contributed a paper on "Equilibria of Hydrosilicic Acid. Pt. I. Mixtures of Hydrofluosilicic and Hydrofluoric Acids," which contained a record of experiments on the titration of these acids with alkali in presence of phenolphthalein or methyl orange, and a theoretical interpretation thereof. Mr. Hudleston stated that they had not been able to purchase even approximately pure hydrofluoric acid, the samples supplied containing over 50 per cent. of hydrofluosilicic acid. Further, the "A.R."-test for determining silica in solutions of hydrofluoric acid was found to be valueless.

Mr. W. C. Reynolds summarised briefly two papers on Interfacial Tension, in the first of which he described a capillarity method of measuring it in C.G.S. units, and adduced results comparing it with the dynamical or "drop" method. In the second he showed that the interfacial tension between two pure liquids, A and B, is the difference between the surface tension of A saturated with B and the surface tension of B saturated with A; that the interfacial tension between pure liquids is constant at any given temperature; and that aqueous solutions of crystalloids behave like a pure liquid. The interfacial tension between aqueous sols of soap and colloids in contact with benzene was found to vary with the age of the contact surfaces. They probably conform to the law at the moment of contact, but owing to surface concentration the tension changes. In soap sols the concentration is complete in a few minutes, but in colloidal sols generally it proceeds for several hours. In cases where the interfacial tension is not constant, its measurement affords a means of detecting chemical or electrical action, or the presence of impurities in liquids.

Mr. F. W. Atack criticised the Hantzsch-Werner hypothesis of the geometrical isomerism of carbon-nitrogen compounds, and dealt with the constitution of oximes, and Prof. Bassett communicated a short note on the system: picric acid—phenylacridine.

THE FARADAY SOCIETY.

A joint meeting of the Faraday Society and the Manchester Literary and Philosophical Society was held in Manchester on February 11. The chair was first taken by Sir Henry A. Miers, and then by Prof. A. W. Porter.

Dr. Allan Ferguson read a paper entitled "Studies in Capillarity. I. Some General Considerations and a Discussion of Methods for the Measurement of Interfacial Tensions." He pointed out the importance of accurate measurements of surface tension in view of the developments in colloid chemistry, and stated that a critical study of the various methods in systematic use had shown the following to be the most promising:—(1) The measurement of large drops and bubbles. (2) The measurement of the maximum pressure required to release a bubble of air from the end of a capillary tube immersed in the liquid. (3) The measurement of the maximum pull on an anchor ring, which is immersed in the liquid and then slowly withdrawn from it. The capillary-tube method was discussed, and it was shown that a comparatively simple mathematical analysis for the ascent of a liquid in a capillary tube gave the sufficiently accurate expression:—

$$2a^2 = rh\left(1 + \frac{1}{3}\frac{r}{h} - 0\cdot1288\frac{r^2}{h^2}\right),$$

where a^2 is the specific cohesion, and h the height to which the liquid rises in a tube of radius r.

Dr. Ferguson then read a second paper by himself and Mr. P. E. Dowson on "A Modification of the Capillary-tube Method for the Measurement of Surface Tensions." In this new method the meniscus is forced down to the end of the capillary immersed vertically in the liquid, and the pressure required to effect this is measured on a manometer. This procedure avoids most of the difficulties of the usual method. Temperature measurements and control become simple, and calibration of the capillary is not necessary, for measurements are always made in one definite position—at the end of the tube. Any manometer of sufficient delicacy may be used, such as a differential manometer, or one of the simple sloping-tube type. The following values were obtained for the surface tension in dynes/cm.:—Benzene (15° C.) 29·66; toluene (15° C.) 29·23; methyl propionate (15·5° C.) 26·09.

In the long discussion which followed, Prof. Porter said he had had considerable experience in measuring the surface tension of mercury; he had photographed large drops and had found that the method of illumination was an important factor. He regarded the new method given by Dr. Ferguson as much more satisfactory than that of measuring the capillary rise. Mr. F. C. Thompson said that he was especially interested in the applications of surface tension to metallurgical problems and gave examples in connexion with the constitution of steel. Dr. R. S. Willows said that surface tension data were of particular importance in connexion with the formation of emulsions, and he asked for a simple method he could apply. Prof. Haldane Gee referred to the work of Quincke, who is still working at the age of 87 on the subject at Heidelberg, and who has recently advanced a new theory of the constitution of glass depending on surface tension. Prof. A. Lapworth referred to the values obtained by Dr. Ferguson and Mr. Dowson for benzene,, which were found to change with time; this required further investigation.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS.

LORD MOULTON ON "KEY" INDUSTRIES.

A luncheon was given by the Association of British Chemical Manufacturers on February 16, at Prince's Hotel, W., in honour of its president, the Rt. Hon. Lord Moulton, for his services to chemical industry during and after the war. Among those present were the Rt. Hon. Sir Alfred Mond, the Rt. Hon. Lord Inverforth, Sir William Pearce, Sir William Pope, Sir Henry Birchenough, Sir Sydney Chapman, Sir Philip Magnus, Sir H. McGowan, Prof. W. H. Perkin, Prof. H. E. Armstrong, Dr. M. O. Forster, Mr. Max Muspratt, and Mr. W. J. U. Woolcock.

Sir William Pearce, who presided, in proposing the health of Lord Moulton, referred to his accomplishments as senior wrangler, great lawyer, administrator, chemist and scientist, and said that the recent passage of the Dyestuffs (Import Regulation) Bill through the House of Lords was largely due to his advocacy. That Act must now be supplemented by further legislation to secure the future of the synthetic organic chemical industry, a branch of the main industry which had long been recognised and fostered by the German Government as one of the most important. It was essential that our Government and country should recognise its supreme value and legislate accordingly.

Lord Moulton, in his reply, said that this was a most critical moment in the existence of the British chemical industry and, through it, in the existence of England. During four years of the war he had endured terror of what the German chemical industry had enabled our enemies to do; he was always urging the Treasury to buy ahead from Chile the nitrate which the Germans were making in unlimited quantities at home, and he was afraid to think what would have happened if Germany had concentrated her submarine attack on that narrow line through the Panama Canal by which we obtained our supplies. In this, and in many other ways, we were reminded of the consequences of the neglect by the British nation and the British Government of the chemical industries during the 30 or 40 years before the war.

Referring to the old war-cry of Free Trade *v.* Protection, Lord Moulton said that we in this country were too fond of adopting political formulæ and calling them principles. As an old Free Trader, he used to say that the quickest way to obtain national wealth and to enjoy it was to buy in the cheapest market. That definition must now be elaborated as follows:—"If your main object is the rapid acquisition of wealth and the enjoyment of wealth, *and if you are sure of continuous peace*, then the best way is to buy in the cheapest market." Unfortunately we could not rely on a continuous peace, and the rapid acquisition and enjoyment of wealth could only be regarded as the highest good if it included the perfect development of our greatest asset—our own people. We had allowed ourselves to grow up as a nation utterly insufficient for ourselves, depending on others for the supply not only of manufactured goods, but also of many raw materials. When he looked back on the confident utterances of the old-time Free Traders, he was surprised that some of them did not insist that we should contract with Krupp for our war material and accept his tender if it were the lowest. Now they knew that they dare not be dependent on a foreign country for munitions of war; but they did not recognise that there were other things just as essential for use in peace. We no more dare leave our great industries at the mercy of a foreign country than we dare trust to a foreign country for our guns and ammunition. It was quite impossible to prop up every industry that did not make itself industrially remunerative, but when as a result of long national neglect the country had called on industries to initiate and develop new branches during the war, to expend capital on them and to develop research, it was the country's duty to protect those industries until the crisis was passed; and to think that they could withstand unrestricted competition while yet in a state of infancy was sheer folly. The problem would not be permanently solved by means of subsidies or import duties. His experience during the war had given him unlimited faith in British chemistry, both theoretical and industrial, and he declined to regard our chemists as in any way inferior, except as regards experience, to those of any other nation. He had always supported the system of licensing under which protection was secured for British goods so long as they were produced at home at fair prices and of equal quality; such a system would afford our manufacturers a breathing space in which to develop, not as a favour but as a right, their power of production until they needed no help and feared no enemy.

CORRESPONDENCE.

THE FINE CHEMICAL INDUSTRY.

(Communicated by the Association of British Chemical Manufacturers.)

Sir,—We, the undersigned, makers of fine chemicals, extended our research and manufacturing plant at the urgent appeal of the State during the tremendous years that followed 1914, in order to secure those essential products of science without which victory could not be attained. The full record of wartime achievements in the sphere of fine chemicals would read like a romance were the full history disclosed.

This key industry is now endangered, and unemployment is rife in it, owing to the flood of imports from abroad which, among other circumstances, the present condition of the exchanges makes devastatingly possible.

We desire to submit to public knowledge the following facts:—

1. The application of chemical science to industry is a necessary factor for the preservation of our world position in commerce. It is also true to say, not only that the chemist and the laboratory are in this country of a fine chemical industry not inferior pivotal in the development of our industrial and commercal resources and wealth.

2. At very consderable cost, essential plant was erected during the war-years, and all of it can now be put to peaceful purposes for the continuance in this country of a fine chemical industry not inferior to Germany's. But, under the present unfair economic circumstances, this plant must become idle and useless, unless the State takes measures for its safeguarding.

3. The fine chemical industry, mobilised and expanded in the hour of the nation's needs, provided during the war—to give a few examples—(*a*) essential medicinal preparations for naval, military, and civilian hospitals; (*b*) the higher forms of explosives and gases; (*c*) photographic chemicals for aerial use; (*d*) research chemicals, without which the development of many new industrial processes would have been impossible.

4. British science is no whit inferior to that of competing nations, nor are British chemical manufactures inferior in quality.

We feel it is our bounden public duty to make known to the country the national importance of an industry which is indeed a key to the unlocking of many doors of economic wealth in the future.—We are, etc.,

NEWS AND NOTES.

Petroleum Research.—The American Petroleum Institute intends to create a department of research, and its board of directors has recommended that three engineers be appointed, one to investigate oil-field problems, another to investigate the refinery problems, and a third to deal with problems relating to the distillation of petroleum and its products.

Colloid Chemistry.—Attention is drawn to a discussion of research problems in colloid chemistry by Dr. W. D. Bancroft which began in the January number of the *Journal of Industrial and Engineering Chemistry*. In his first communication Dr. Bancroft discusses seventeen problems under the general head of "Adsorption of Gas or Vapor by Solid," fourteen under "Contact Catalysis," three under "Adsorption of Vapour by Liquid," and nine under "Adsorption of Liquid by Solid."

Improved Yield of Methyl Alcohol in Wood Distillation.—A report will soon be published by one of the Government laboratories outlining experiments which have indicated the possibility of practically doubling the yield of methyl alcohol from the distillation of certain woods if a very small percentage of a certain chemical compound be first sprayed upon the wood. Encouraging results have been obtained in the laboratories from the use of sawdust, but it remains to be seen whether any practical difficulties will limit the size of pieces which can be treated. If such improved yields can be obtained commercially in the treatment of wood waste, certain perfected methods for the distillation of these wastes will be put on a very sound basis.

Ethyl Alcohol from Wood Waste.—The United States Forest Products Laboratory at Madison, Wisconsin, has prepared a pamphlet describing the production of ethyl alcohol from wood waste. The pamphlet includes estimates of plant requirements and cost data compiled from recent experiments at the laboratory. It is shown that with 180 tons of wood waste available daily, 3600 galls. of alcohol can be produced at a cost approximating 25 cents a gallon. The soft woods give the highest yields of 95 per cent. alcohol per ton of wood; white spruce heads the list with 25·8 galls., longleaf pine is next with 25·1 galls. The smallest yields are obtained from hard maple, red oak, cottonwood, and slippery elm, the first of these yielding but 9·1 and the last 6·0 galls. per ton.

AUSTRALIA.

South Australia.

Lignite Deposits.—A recent report of the Department of Mines states that the rise in the cost of imported fuel during recent years and the dislocation of industry through the interruptions in marine transport have drawn attention to all domestic sources of supply. In this connexion there is a revival of interest in the lignite deposits near Moorlands, where prospecting is now being actively pursued.

The lignite exposed in the workings has a somewhat variable appearance. The dull earthy and structureless body contains fragments of partly carbonised wood in which the fibres are plainly visible. There are a few irregularly shaped pieces of lustrous lignite and many traces of resin throughout the bed. The coaly matter contains much pyrites disseminated throughout the body of the carbonised wood. The following methods of utilising this lignite have been suggested:—(1) The generation of power with the aid of steam produced from specially designed furnaces burning the raw lignite. (2) The generation of producer gas from the raw fuel and the recovery of by-products. (3) Utilisation of the pulverised fuel for raising steam. This method involves the artificial drying of the lignite. (4) In the form of briquettes manufactured from the lignite after drying. (5) The carbonisation of the lignite with recovery of the by-products by distillation.

In view of the vital importance of fuel supplies to the State, the Government has purchased a modern drill, and boring operations, designed to prove the extent and quality of the brown coal deposits of the State, are in progress in the vicinity of Adelaide. The Government has also allocated £5000 for experiments on pulverised coal from Leigh Creek. The tests will be designed primarily to ascertain the value of this coal for use in railway locomotives, but they will be extended to other domestic fuels, such as the lignite of Moorlands.

BRITISH INDIA.

First Forecast of Winter Oil-seeds.—The total area under rape and mustard, excluding the mixed crop in the United Provinces, is estimated at 2,835,000 acres, or 13 per cent. below the estimated area in 1919–20. The percentage distribution of this area is as follows:—United Provinces 40·2, Bengal 19·4, Punjab 16·2, Bihar and Orissa 11·7, Assam 4·6, Bombay and Sind 4·7, North-West Frontier Province 1·8 per cent. The total estimated area under linseed is 1,755,000 acres (excluding the mixed crop in the United Provinces), representing a decrease of 23 per cent. The proportion sown by each province is:—Central Provinces and Bihar 35·3, United Provinces 29, Bihar and Orissa 23, Bengal 5·5, Bombay 5 and Punjab 1·2 per cent. Owing to deficient rainfall, the conditions for sowing were generally unfavourable. Rain is urgently wanted in most of the provinces and the condition and prospects of the crops are only fair.—(*Indian Trade J., Jan. 7.*)

JAPAN.

Petroleum Production.—The output of crude petroleum in Japan during the first six months of 1920 was 38,181,675 galls., compared with 38,891,918 galls. during the same period of 1919. Over 99 per cent. of the production was obtained in the prefectures of Niigata (Echigo) and Akita.—(*Sekiyû-Jihô, Nov., 1920.*)

CANADA.

Maple Sugar "Sand."—During the evaporation of maple sap to the state of syrup, a precipitate technically known as "sand" is deposited. It contains 60—80 per cent. of calcium malate, and its annual production from all the trees in the United States and Canada is estimated to be 100—330 tons, corresponding to 50—165 tons of calcium malate. Previous to the war it was bought by a German manufacturer of fine chemicals, and efforts are now being made to interest chemists in other countries in the possible uses to which this by-product may be put. As the acid constituent of baking powder, calcium bimalate gives excellent results, but it can hardly be produced as cheaply as calcium acid phosphate or even cream of tartar. Other applications, either of the normal or acid salt or of malic acid, are being investigated. In the case of no other source of malic acid can extraction be so readily effected, it being necessary only to convert the normal to the acid salt, and the latter being much more soluble in hot than in cold water is easily separated in a comparatively high state of purity by re-crystallisation.—(*Proc. 27th Annual Meeting of the Vermont Maple Sugar Makers' Association.*)

FRANCE.

Industrial Notes.—*Chemical Industry.*—The closing down, either partial or complete, of factories in the dyeing, bleaching, and leather industries has led to a weaker demand which has affected prices. Wholesale dealers, fearing a sudden fall in prices, are eager to dispose of their stocks, even on unfavourable terms. On the whole, however, there is no panic and prices are steadily finding their level without any State interference. German competition is proving a great stimulant and many firms are extending their plant in order to increase output. The Tencé firm, which has a plant at Aubervilliers, is building a new factory at Bernes, near Persan-Beaumont, for the production of sulphates, chlorides, nitrates, and of hydrochloric, sulphuric and nitric acids in both pure and commercial grades. The Compagnie Nationale des Matières Colorantes has just begun to produce alizarin and other basic dyes, in addition to indigo, at its works at Villers-Saint Paul.

Metallurgy.—The outlook in the metallurgical market remains practically unchanged; iron ore is in poor demand and there are large stocks of minette. The warning given to German firms that unless they supply France with the coal and coke she needs their supplies of iron ores will be cut off, have caused them to seek for new sources of supply, notably in Sweden. Lorraine is now supplying the Ruhr district with only 10 per cent. of its requirements, which compares with 50 per cent. before the war. On the whole, there is a feeling of confidence in French metallurgical circles. Owing to stocks of raw material being very low, the French will be able to take advantage of the fall in prices in replenishing them. Prices of wrought iron and steel have fallen considerably, and French pig iron is now sold at a lower price than the British. The chief competition comes from Germany, where production costs are lower than in France.

GENERAL.

Research Chemicals and the Dyestuffs Act.—In response to an inquiry made by the Institute of Chemistry, the Board of Trade has intimated that it will issue general licences under the Act to approved research institutions for the importation of small quantities of organic intermediate products. The licences will cover periods of three months and be limited only as to total quantities. A detailed return of the quantities of each product actually imported must be made at the end of the three-monthly period.

The Textile Institute.—Colonel F. R. McConnel, of Manchester, is to succeed the late Sir A. Herbert Dixon, Bart., as president of the Institute. At the invitation of the Basle Chamber of Commerce the Annual Spring Conference will be held from May 17 to 20 at Basle, in co-operation with several leading textile organisations in Switzerland. During the conference lectures will be given on "The Dye Industry and its Future," "The Industrial Application of Electricity," "The Financial Situation," and "The Structure of Textile Fabrics." The programme includes facilities for visits to textile and other works.

Industrial Alcohol in Switzerland.—At a meeting held on January 5, convened by the Swiss Society of Chemical Industry and attended by representatives of all the larger firms which use alcohol in their manufactures, a resolution was passed condemning the decision of the National Assembly to extend the alcohol monopoly to industrial spirit. The meeting protested that the decision had been made without consultation with those whom it would affect, and affirmed that at the present time the restrictions attending such an extension of the monopoly would be fatal to the country's export trade.—(*Schweiz. Chem.-Z., Jan.* 25, 1921.)

Patents in Greece.—The first Greek patent law, passed early in the autumn of 1920, provides that every patent shall be granted on priority of application, shall cover only one invention, and have a life of 15 years, reckoned from the day following the date of application. The ownership of a discovery made in an industrial or commercial establishment is vested in the discoverer, and patents must be satisfactorily exploited within three years after coming into force, although this does not apply to nationals of countries that offer reciprocal treatment. In the event of a patent being declared of public utility, the owner must allow others to exploit it on payment of compensation. Foreign applications must be made through an agent resident in Athens and be subject to local jurisdiction. Where patents are registered in countries that allow reciprocal treatment the Greek law allows 12 months' priority from the date of the patent. Applications must be in Greek and be accompanied by an official certificate from the country in which the patent is registered. Patent specifications will be published at once, but may be kept secret for a year if requested.—(*Z. angew. Chem., Dec.* 17, 1920.)

State of the Swedish Chemical Industry at the end of 1920.—The situation in the Swedish chemical industry has been growing worse, and in consequence of falling prices in the world's markets and of the high wages now paid in Sweden, manufacturers have either to close down or to produce at a loss. Many branches of the industry are demanding increases in import duties. Hitherto ammonium sulphate has been imported freely, but the body which represents all the Swedish manufacturers of this fertiliser is asking for an import tax of 15 kronor per quintal (about £8 10s. per long ton, at par); the yearly output of ammonium sulphate, about 9000 metric tons, is far in excess of the home demand, as cyanamide is chiefly used for nitrogenous manuring, and the export trade is suffering severely from German competition. No improvement has taken place in the soap industry; sales of soft soap are poor and prices have fallen; most of the factories hold big stocks of soap and produce only sufficient to keep plants in operation. The amalgamation of the Kväveindustrie (nitrogen industry) and the Trollhätte Cyanidverk companies has fallen flat, and the necessary new capital not having been obtained, the directors have notified the suspension of operations. The Swedish Government has appointed an expert advisory commission to investigate the bad economic situation.—(*Z. angew. Chem., Jan.* 7, 1921.)

"**Monazite (1913—1919)**" (pp. 15, price 6d.) has been recently published by the Imperial Mineral Resources Bureau as an advance "part" of its annual volume on the Mineral Resources of the British Empire and Foreign Countries. Monazite, essentially a phosphate of the cerium earths, owes its commercial value to the presence of a variable amount of thoria which is extracted by chemical treatment and marketed in the form of thorium nitrate for use in the manufacture of gas mantles. The mineral is widely distributed in nature, but few deposits have been discovered which contain thoria in sufficient quantity to justify commercial exploitation. It is found in the form of an alluvial sand associated with other minerals, such as magnetite, ilmenite, garnet, and zircon, from which it is separated by hydraulic and electromagnetic methods to produce the concentrate as it is marketed. With the exception of small quantities of thorite and thorianite obtained from Norway and Sweden, the first deposits to be worked for monazite were those situated in the Carolinas. These deposits, patchy in distribution and poor in quality, could not compete with those discovered later in Brazil, which supplied the world's requirements until the monazite from Travancore, India, appeared on the market about the year 1911. The earlier history of the Travancore deposits, and the final obliteration of the German interests, have been already fully referred to in the pages of this *Journal* (*cf.* S. J. Johnstone, J. **33**, 55, **35**, 811, and **37**, 373 R). The separated monazite is the highest grade on the market, containing about 8½ per cent. of thoria as compared with 6 per cent. in the best of the concentrates obtained from the Brazilian sands. To illustrate the variable thoria content, reference may be made to monazite discovered in such widely separated countries as Nigeria, Queensland, Malaya, and the United States, which, even when concentrated by the most perfect means commercially available, commonly contain no more than 4 or 5 per cent., and frequently considerably less. The present price of monazite is stated to be £4 12s. 6d. per unit of thoria per ton at the mine in Travancore. The c.i.f. value at European ports depends upon the cost of freight. In June, 1920, it was about £6 10s. per ton.

Statistics quoted include the world's production of monazite, imports into the United Kingdom (for some unstated reason these are given in values), and into the United States.

World's Production of Monazite.

* Estimated.

Thorium nitrate, worth about 23s. per kg. before the war, is now selling at about 38s. Before the war this country was dependent upon Germany; since the war and up to within the last year or two nitrate was imported from the States, but now British manufacturers apparently supply home requirements.

Value of Imports and Exports of Gas Mantles to and from the United Kingdom.

Year.	Imports.	Exports. Domestic produce.	Exports. Foreign produce.
	£	£	£
1913	302,576	32,566	5650
1914	199,299	47,400	4359
1915	236,075	93,960	4848
1916	57,067	144,292	7491
1917	24,106	94,058	—
1918	26,815	103,297	—
1919	31,771	88,893	—

The mixture of oxides in gas mantles is said to be derived from a mixture containing about 99 per cent. thorium nitrate and 1 per cent. cerium nitrate. Large quantities of cerium compounds are obtained as by-products in the manufacture of thorium nitrate, and new uses for this product, hitherto largely wasted, would be welcomed by the industry. At the present time the cerium is used for the manufacture of the alloy ferro-cerium, which usually contains about 30 per cent. iron, and which is used in the manufacture of sparking devices for carbide lamps, gas jets, and automatic cigar lighters. Cerium has also been suggested as a deoxidiser in the manufacture of steel and also in the "thermit" process for the reduction of metallic oxides, and its salts are used in the manufacture of flaming electric-arc lamps, in glass making, ceramics, and in medicine. Monazite is the chief source of mesothorium, which closely resembles radium in its properties. The amount present is only a few milligrams per ton of the monazite and apparently it is not extracted by the English manufacturers of thorium nitrate, although at least two manufacturers are producing mesothorium from monazite in the United States. Mesothorium is sold on the basis of its radio-activity compared with radium bromide, and was worth (June, 1920) from £6 to £8 per milligram.

In this connexion reference may be made to three recent publications in the United States, viz., "The Incandescent Gas-Mantle Industry" (United States Tariff Commission, 1920), "Thorium, Zirconium and Rare-Earth Minerals in 1919 (U.S. Geological Survey, 1920), and "The Mineral Industry" for 1919 (New York, 1920). The last states that during the war American manufacturers of thorium nitrate firmly established themselves, and every effort is now being made to pass protective legislation to prevent the flooding of the American market with low-priced German thorium nitrate, and claims that it is evident that a high duty should be placed on all imported thorium nitrate if the welfare of the American industry is to be considered, as the German producers have the advantages of cheap labour and longer hours, and the American producers cannot hope to compete with them. In the States prices remained comparatively firm throughout 1919, monazite sand ranging from $38 to $42 per unit, duty paid, equal to $228 to $252 per metric ton for a sand carrying a minimum of 6 per cent. of thoria. The prices of the nitrate remained steady throughout the year, ranging from $3.75 to $4 per lb. A small quantity of ferro-cerium, estimated not to exceed 10 tons per annum, is produced in the United States.

According to "The Incandescent Gas Mantle Industry," the productive capacity of the American plants shows an increase of 300 per cent.; 149,850 lb. of thorium nitrate was produced in 1913, and 439,304 lb. in 1917. The imports amounted to 1880 lb. in the latter year and 112,000 lb. in 1913. The same publication remarks that an *ad valorem* duty has been levied on the crude raw material, the refined intermediate product and the finished article, and if the duty is calculated on the basis of the content of the constituent of principal value, namely thoria, specific rates of duty obtaining in 1914 were as follows:— Monazite sand, $0.315 per lb. of thoria contained; thorium nitrate, $1.44 per lb.; and gas mantles, $7.48 per lb.

Finland in 1919.—The chief natural resources of Finland is timber, which covers an area of 77,200 square miles and is estimated to last about 145 years on the basis of an annual production of 300,000 tons of chemical pulp and 200,000 tons of mechanical pulp. Water power is also abundant, but only 150,000 h.-p. is in use, about 1,460,000 h.p. remaining unutilised. Several mines have been worked in East Finland, including the Outokumpu copper pyrites mine, which is estimated to contain at least 230,000 tons of copper and over 2 million tons of combined sulphur (*cf.* J., 1919, **27 R**, **47 R**).

Wood pulp and paper constitute the most important industries. Trade in these commodities was formerly mostly with Russia, although since 1903 there has been a steady market for Finnish wood pulp in Denmark, Germany, Holland, Belgium, England, and France. The following table gives the quantities (long tons) of mechanical pulp and board exported in 1913 and 1919:—

	1913.	1919.
Wood Pulp.		
Wet	8,916.5	12,504
Dry	39,750	50,861
Total	48,666.5	63,365
Pasteboard (wood)	52,884	910

Nearly all the wood pulp and board exported is supplied by the twenty-three mills belonging to the Finnish Wood Pulp Mill Union (Finska Trasliperiforeningen), which has a combined capital of 100 million Finnish marks (about £4,000,000 at par), and a total annual capacity of about 150,000 tons. Of the 1919 production, 5518 t. was sold in Finland and 74,609 t. exported, mainly to Germany, France, and England (in the order named).

The cellulose or chemical wood-pulp industry prospered in 1919, in spite of Canadian competition; 15 per cent. of the sulphite pulp and over 35 per cent. of the sulphate pulp were shipped to the United States. Almost all the exported material is produced by the members of the Finland Cellulose Association (Finska Cellulosa Foreningen), which comprises 18 sulphite mills (capital £8,000,000, annual capacity about 190,000 t.), and 6 sulphate mills (capital £4,000,000 and capacity 66,000 t.). The annual report of the association gave the production figures for 1919 as 68,900 long tons of sulphite pulp and 26,870 t. of sulphate pulp. Exports were as follows (long tons):—

	1919.	1913.
Chemical Wood Pulp.		
Wet	2,850	3,125
Dry	69,804	72,728
Total	72,654	75,853

Russia was the most important foreign market for Finnish paper until 1917, but when this was closed considerable difficulty was experienced in securing new markets owing to Swedish and Norwegian competition. Trade revived in the late summer of 1919, and increasing quantities have been marketed, particularly in England and the United States. The capacity of the 31 mills represented in the Finska Pappersbruksforeningen is estimated at about 220,000 tons, and their combined capital is over £10,000,000 (at par); the 1919 output was about 95,000 tons, and the sales 66,970 t., of which 44,800 t. was exported.

The metal industries have recently shown some recovery; production has increased by about 30 per cent. over that of 1918 and has reverted to its main object, viz., that of supplying the country with machines, tools, and metal goods. The newly instituted eight-hour day is regarded with misgiving, but as it has also been adopted in Scandinavia and other countries, it is hoped that the industry will not be seriously affected.

Finland has two important Portland cement factories, with a combined annual capacity of 675,000 barrels, but this will soon be doubled; these factories also make lime for use in the cellulose factories. Coal is needed for this industry.

Raw materials having become available, the cotton factories resumed full work in the latter half of 1919, and the prospects of the industry are considered bright. It is stated that the textile manufacturers are very dissatisfied with the way they are treated by the German dyestuff firms, and that there is a good opening for other foreign dyes of good quality.

The manufacture and production of matches could become a very important industry, as 90 per cent. of the raw materials, notably poplar wood, is indigenous. Production was increased 10 to 15 times during the war; work was suspended when export to Russia was stopped, but resumed in 1918. The Swedish match trust has recently obtained control of the two largest factories and purchased a third. Exports of matches were 8·5 tons in 1913, 290 t. in 1918, and 855 t. in 1919.

The tar industry, formerly important, has declined greatly, production and export having become very small; the quantity of tar exported in 1918 was 529 galls., as against 13,636 galls in 1913.

The six sugar refineries were combined in January, 1919, into one limited company (Finska Socker), with a paid-up capital of 50 million marks (about £2,000,000 at par) and a total annual capacity of 60,000 tons of sugar. Sugar-beet cultivation has commenced on a small scale, and a factory began work in February, 1920.

Imports into Finland in 1919 were valued at £32,537,485 (£1 = 75·4 Finnish marks), and included:—Drugs, £117,252; gums, resins, etc., £535,150; oils and greases, £2,636,300; perfumes, £23,213; minerals and manufactures, £632,997; chemicals, £295,170; explosives, £70,961; colours and dyes, £181,698; and metals and manufactures, £2,271,067. Of the total imports, the United Kingdom supplied 27 per cent., followed by the United States with 25 per cent. The exports in 1919 were valued at £11,338,468, of which 43 per cent. was shipped to the United Kingdom.—(*U.S. Com. Rep. Suppl., Nov.* 11, 1920.)

LEGAL INTELLIGENCE.

Agency Claim against a Company Manufacturing Salicylic Acid. *E. T. Pearson and Co. v. Sheppard's Chemical Works, Ltd.*

In the Chancery Division, on February 9, Messrs. E. T. Pearson and Co., of London, made an application that the liquidator of Sheppard's Chemical Works, Ltd., should be directed to admit their claim for £3918 as creditors of the latter company.

For the applicants it was stated that they were appointed sole agents for the sale of the salicylic acid manufactured by Sheppard's, and, as the agency was for a term of seven years commencing in June, 1916, it was claimed that the liquidation of the company in June, 18 constituted a breach of contract. The applicants had earned over £1400 in commission on sales, and there was evidence that the sale was increasing

On behalf of the liquidator it was stated that Sheppard's, Ltd., had not manufactured salicylic acid since it went into liquidation and was re-constituted as a new company, as the chemical could not be sold at a profit, the price having dropped from 22s.—23s. per lb. in 1916 to 2s. per lb. just before the company ceased operations. It was contended that the clause providing for the payment of £1000 when the agreement was ended was not a measure of damages.

Mr. Justice Astbury said that when there was a seven years' agreement it was not an answer to a breach of contract to say that the chemical could not be produced at a profit; the applicants, however, could not get more than the £1000 payable if the agency did not run the full term.

The parties finally arrived at a settlement by which the applicants, who held a sum of £273 for goods sold, were to retain £150 in full satisfaction of their claim and costs, the remainder to be held by the liquidator as a sum out of which the applicants would be indemnified against any claim brought against them in respect of bad quality of goods sold under the agency agreement.

OFFICIAL TRADE INTELLIGENCE.

(From the Board of Trade Journal for February 10 and 17.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number:—

Locality of Firm or Agent.	Materials.	Reference Number.
British W. Indies	Galvanised sheets	223
" ..	Glassware, crockery	224
Canada	"Stainless" steel, patent medicines	191
"	Pig iron	193
"	Indian linseed oil	*
"	Varnish	*
South Africa ..	Roofing (felt and other), rubber, paper, vulcanised fibre	222
" ..	Tinplate	222a
Belgium ..	Glass, earthenware, porcelain ..	200
France	Chemicals and raw materials, especially for the soap and perfumery industries	228
Italy	Lubricating oils, paint, varnish ..	207
Latvia	Shellac, gum sandarac, gums, resins, ceresin, montan wax, gilsonite, nigrosin	230
Spain	Tinplate, heavy chemicals, paper ..	209
Morocco ..	Glassware, china	235
Argentina } Uruguay }	Metals, chemicals, soap, dyes, candles, tinplate	241
United States ..	China, earthenware, glassware ..	211
" ..	Chemicals	240

* The High Commissioner for Canada, 19, Victoria Street, London, S.W. 1.

Market Sought.—A Canadian firm manufacturing oak and hemlock sole leathers wishes to get into touch with importers in the U.K. [Inquiries to the Canadian Government Trade Commissioner, 73, Basinghall Street, London, E.C. 2.]

TARIFF, CUSTOMS, EXCISE.

Antigua.—The revised rates of export duties on sugar, syrup, and molasses, with effect from January 1 to December 31, are given in the issue for February 10.

Austria.—Among the articles for which import licences are still required are sugar, malt, honey, paraffin, alcoholic beverages, vinegar, opium, essential oils, benzol oils, mineral oils, artificial silk, certain kinds of glass and glassware, stonewares, asbestos wares, earthenware, certain metals and wares, salt, many chemicals, varnish, perfumery, candles, and soap.

Articles for which export licences are still required include sugar, molasses, oil seeds, raw hides and skins, fats and oils of all kinds, vinegar, pyrites, certain ores, chalk, magnesite, opium, camphor, dyeing and tanning materials, gums, resins, mineral oils, tar, vegetable fibres, paper pulp, paper, rubber waste, cement, certain metals and wares, caustic potash and potassium salts, caustic soda, Glauber's salt, white lead, lead oxides, ammonia, and many chemicals.

Belgium.—Margarine and vinegar may now be exported without licence.

British India.—The revised Tariff Valuations are set out in the issue for February 17. They supersede those dated November 20, 1919, and take effect as from January 1.

Among the articles admitted duty free are hops, salt (under certain conditions), raw hides and skins, oil-seeds (under certain conditions), raw wool and cotton, wood pulp, quinine, trade catalogues, and certain substances when used for the weaving of cotton or the baling of cotton goods, *e.g.*, aniline blue, sodium sulphates, sodium carbonate, magnesium chloride and sulphate, zinc chloride, china clay, starch, sizing paste and wax, farina, glutina, and glycerin substitutes.

The export of cinchona bark is prohibited to all destinations except the U.K.

Bulgaria.—Revised export duties affect, *inter alia*, skins, hair, edible fats, certain oil-seeds, opium, rose oil, animal waste, scrap metals, paper and rubber wastes.

China.—A surtax of 10 per cent. of the existing customs duties will be levied as from March 1.

Egypt.—Sesame can now be exported without a special licence.

France.—The export duty on dephosphorisation slag is fixed at 1.50 fr. per 100 kg.

France and Algeria.—The "coefficients of increase" on calcium carbide, glass, paper, and cardboard have been modified.

French Colonies.—The export of sugar, crude gold, platinum and silver is prohibited to all destinations except France and French colonies.

Germany.—A list showing the export taxes leviable under section 6 of the Ordinance of December 20, 1919, may be seen at the Department, 18, Queen Anne's Gate, London, S.W. 1.

The import of lard, goose-grease, beef marrow and other fats similar to lard (but not margarine) is permitted without licence as from February 15.

Grenada.—An additional export duty has been levied on cocoa under certain conditions.

Italy.—Import may be authorised under certain conditions of certain glasswares, laboratory glassware, and photographic films.

Kenya.—It is proposed to allow free of customs duty the import of drugs, medicines and rectified spirit to be used solely in the compounding of drugs and medicines.

Malta.—Paraffin and stearin may now be imported duty free.

Palestine.—The import of explosives, nitre, salt, and "hashish" is prohibited.

The import of cocaine, sulphonal, picrates, and potassium and sodium chlorates is permitted only under special licence.

Portugal.—The full text of the Bill which provides for the complete revision of the customs tariff is set out in the issue for February 10. It is proposed to abolish, with a few exceptions, the surtaxes on import duties. The customs duties will be collected solely in gold. The proposed new schedule of duties covers practically all classes of goods.

Sweden.—Export prohibitions have been removed from peat, lard, tallow, milk powder, dripping, raw rubber, guttapercha and balata, caustic potash, potassium carbonate, chloride and sulphate, tartar emetic, salts of gold, platinum and radium, chlorides of tin, indigo, and unsweetened condensed milk.

Switzerland.—Export licences are still required for cocoa, chocolate, raw hides and skins, glue stock, fibres for the manufacture of paper, cotton waste, porcelain insulators, raw iron and wares thereof, copper ore, copper, gold, silver, platinum, potassium permanganate, saccharin, methyl alcohol, indigo and aniline, anthracene, naphthalene and tar colours not specially mentioned in the general tariff.

Tunis.—Essence of turpentine, and bauxite, may only be exported with the sanction of the Director-General of Finance.

Uruguay.—It is proposed to levy an additional duty of 15 per cent. on all imports, but not on certain oils, sugar, kerosene, charcoal, and a few other substances.

GOVERNMENT ORDERS AND NOTICES.

Overseas Trade (Credits and Insurance) Act, 1920.—By an order of the Board of Trade of February 17, 1921, the country of Austria was added to the Schedule to the Act.

Decontrol of Coal.—The Board of Trade has notified, under date February 14, that the Directions issued August 25, 1920, relating to maximum pithead prices for coal sold for home consumption and for bunkering vessels will cease to have effect as from March 1, 1921.

Prohibited Exports.—The Board of Trade (Licensing Section) announces that, by Order-in-Council, dated February 7, 1921, the export of:—Sulphate of ammonia; superphosphate of lime; basic slag; and compound fertilisers containing any of the foregoing substances is now prohibited under the Fertilisers (Temporary Control of Export) Act, 1920; and the Proclamation of May 10, 1917, as amended by subsequent Orders of Council, is revoked so far as it relates to:—Sulphate of ammonia and mixtures containing sulphate of ammonia; basic slag; manures, compound, containing either sulphate of ammonia, superphosphate of lime or potash; superphosphates. Applications for export licences should continue to be addressed to the Licensing Section, Board of Trade, Great George Street, Westminster, S.W. 1.

Determination of Combustible Matter in Coal Dust and Mixtures Thereof.—The Secretary for Mines has issued notices under the Coal Mines Act, 1911, concerning (*a*) the determination of combustible matter in dust mixtures which contain carbonates (Feb. 14), and (*b*) the testing of dust mixtures which contain such a high percentage of moisture that they cannot be sieved in the manner prescribed by the Regulations (Feb. 7).

(*a*) The sample is ignited in an open vessel to decompose completely the carbonates until the weight is constant; the percentage loss in weight is determined by treatment with acid; and the difference between the percentage losses so obtained is taken as the percentage of combustible matter.

(*b*) The sample, having been well mixed, is dried at 212° F. until the weight is constant, and the percentage of combustible matter is determined as under (*a*).

Dyestuffs Licensing Advisory Committee.—In accordance with the provisions of Subsection (3) of Section 2 of the Dyestuffs (Import Regulation) Act, 1920, the President of the Board of Trade has appointed the following Committee to advise the Board of Trade with respect to the granting of licences under the Act:—Mr. Vernon Clay (Joint Managing Director, Robert Clay, Ltd.); Mr. G. W. Currie; Mr. G. Douglas (Managing Director, Bradford Dyers' Association Limited); Mr. E. V. Evans (Hon. Treasurer, Society of Chemical Industry); Dr. M. O. Forster (Director of the Salters' Institute of Industrial Chemistry); Mr. C. C. Railton (Director, Calico Printers' Association, Ltd.); Mr. H. B. Shackleton (Messrs. Taylor, Shackleton and Co., Shipley); Mr. T. Taylor (Cornbrook Chemical Co., Stockport); Mr. S. A. H. Whetmore (British Dyestuffs Corporation, Ltd.); and Mr. W. J. U. Woolcock (General Manager, Association of British Chemical Manufacturers).

Pending the appointment of a permanent chairman, which it is hoped to make at an early date, Mr. P. Ashley, Assistant Secretary, Industries and Manufactures Department, Board of Trade, will act as chairman of the Committee. The Secretary to the Committee is Mr. W. Graham, and all applications for licences should be addressed to the Secretary, Dyestuffs Advisory Licensing Committee, Danlee Buildings, Spring Gardens, Manchester.

COMPANY NEWS.

SOUTH METROPOLITAN GAS COMPANY.

At the annual meeting held on February 9, the chairman, Dr. Charles Carpenter, stated that the company's Act of Parliament (*cf.* J., 1920, 310 R) authorised the payment of a dividend of 5 per cent. per annum on the issued ordinary stock (6 per cent. on future issues), and a dividend at this rate was now proposed in respect of the past year. The increase in expenditure, of which salaries and direct wages accounted for about 40 per cent. and coal for over 46 per cent., had been met by enhanced profits on the sale of residuals. The production of therms for the year was 70·45 per ton of coal carbonised, and there had been an increase of 5·43 per cent. in the sales of gas. Great trouble was still being experienced in obtaining clean coal, but with the passing of Government control an improvement in quality was to be expected. It was to be hoped that the pre-war practice of exporting much of our best coking coal would not be revived; recovery and marketing of the by-products could be done here quite as well as in Germany, and this course would be followed by great economic advantages to this country. Dye-intermediates were now being manufactured on an important scale, and the company was producing successfully a grade of ammonium sulphate equal to that produced in Germany; it was, however, to be regretted that the export of this material had been placed for two years in the hands of a trust. Given time and encouragement, our chemists could learn dye-making from the Germans, just as the latter had learned shipbuilding from us. Most unfortunately, the Government had not prevented the country being flooded with German dyes, of which £1,881,275 worth was admitted during November last; and it was to be hoped that the heat-resisting glass industry would fare better. It was proposed to promote a Bill in Parliament to make permanent the company's powers to raise capital authorised by the Acts of 1916 and 1918. Notwithstanding the fact that no co-partnership bonus had been paid for the past three years, the employees continued to work in full accord with the management.

TRADE NOTES.

FOREIGN.

The Vegetable Oil Industry of Marseilles.—This industry has of late experienced many vicissitudes, but the outlook on the whole is now brighter. In Marseilles there are 30 seed-crushing firms owning 48 mills and 2011 presses. The import of oil-seeds, normally about 60 per cent. of the total imported into France, and consisting chiefly of sesame, groundnuts and copra, amounted to 321,354 metric tons in 1919, and that of vegetable oils 78,438 t., compared with 589,597 t. and 40,927 t., respectively, in 1913. Olive oil is only of secondary importance to the industry. The French production, about 6000 t. per annum, is not equal to the demand, and supplies are imported from North Africa, Spain and Italy (*cf.* J., 1920, 217 R); the establishment of co-operative mills has proved beneficial. The exports of oil-seeds, oil, and oil-cake from Marseilles in 1919 were 9031 t., 3298 t., and 747 t., respectively, compared with 39,600 t., 52,055 t., and 132,837 t. in 1913. Coconut butter is manufactured on a large scale by four companies, which produced an average of 60,000 t. yearly before the war. Since then this industry has suffered from lack of raw materials and diminished export trade due to the development of the industry in other countries, particularly the United Kingdom, the exports having decreased from 19,510 t. in 1913 to 721 t. in 1918.—(*U.S. Com. Rep., Dec.* 20, 1920.)

The Dye Trade in Holland.—The future of the dye trade in Holland is uncertain, production is small, being mainly confined to three firms, and the textile trade complains that the domestic supply cannot be depended upon. Dyes are therefore being obtained from Germany, although Great Britain, Switzerland and the United States are furnishing an increasing supply; British and American dyes, however, have been criticised for lack of variety. The imports during the first eight months of 1920 amounted to 1825 metric tons (worth £795,330 at par), compared with 1318 t. in the same period of 1918, and included:—Aniline dyes, 1311 t.; other synthetic dyes, 5 t.; synthetic indigo, 350 t.; natural indigo, 5 t.; madder and natural dyes, 84 t.; and dyewood extract, 70 t. About 85 per cent. of the aniline dyes came from Germany, 8 per cent. from Switzerland, and the remainder from Great Britain and America; practically all the indigo and madder came from Germany and the dyewood extract from France.—(*U.S. Com. Rep.*, *Dec.* 2, 1920.)

Foreign Company News.—*Japan.*—Five celluloid companies, the Chigusa Celluloid K.K., Royal Celluloid Co., Kazushiro Celluloid K.K., Juzen Shokai, and Hata Shokai, have combined to form a new company, the Central Celluloid Co., with a capital of 2,000,000 yen (£204,166 at par), of which 1,400,000 yen is paid up.

A company with capital of 1,000,000 yen is to be formed by the Japan Chemical Industrial Co. and other fertiliser manufacturers to develop the phosphate deposits in Hirata, an island south of Hainan Island.

The Imperial Gunpowder Industrial Co., established in November, 1919, with a capital of 10 million yen, to manufacture gunpowder, explosives, chemicals, and dyestuffs, will probably start production in March, but instead of making mining explosives it will manufacture for the naval department.—(*U.S. Com. Rep.*, *Dec.* 21, *Jan.* 25, 1921.)

Italy.—A new company, the Società Generale dei Colori, with a capital of 5 million lire and power to extend it to 50 million lire, has been formed at Milan to manufacture mineral colours, thus introducing a new industry into Italy.—(*Z. angew. Chem.*, *Jan.* 28, 1921.)

Sweden.—It is reported that Lever Brothers, Ltd., will shortly dominate the whole Swedish soap industry by acquiring control of seven soap firms, the combined capital of which is about 10¼ million kronor (about £590,000 at par). Seven per cent. preference shares in a holding company will be given in exchange for shares in the Swedish companies.—(*Z. angew. Chem.*, *Dec.* 17, 1920.)

BRITISH.

Uganda in 1918–19.—In view of the demands made upon this Protectorate by the war, the results achieved during 1918–19 were quite satisfactory, but as new capital has not been available since 1914, industrial enterprise has been restricted to its former channels. Cotton is the chief product; the value of the crop in the year under review was £965,951, and the area under cultivation, now being rapidly extended, was nearly 150,000 acres. Para rubber was grown over an area of 11,255 acres, and production is increasing yearly; 113 tons was exported. Ceara and Funtumia rubber do not repay exploitation. The production of oil-seeds could be extensively developed; only small quantities of groundnuts, castor seed and sim-sim are at present obtained. The forests of Uganda would well repay exploitation.—(*Col. Rep.—Ann.*, *No.* 1054, *Dec.*, 1920.)

Zanzibar in 1919.—The most important industry in Zanzibar is the cultivation of cloves, which was begun in 1818 and now covers an area of 52,000 acres, with 4,700,000 trees in bearing in the islands of Zanzibar and Pemba. The output averages 6250 tons, heavy crops being produced every 3 or 5 years; the 1918–19 crop was 12,946 t., the largest on record. Coconut cultivation ranks next in importance, and the 48,000 acres planted to this crop could be considerably extended. The copra is badly prepared and compares unfavourably with the Ceylon product; 14,177 t. was exported in 1919. Rubber is obtained from *Landolphia Kirkii*, but there was no crop in 1919; the cultivation of the Ceara rubber tree, attempted unsuccessfully in 1907, has been abandoned. Other crops grown include rice, sugar, areca nut, cassava, chillies, castor plant, kapok, cinnamon, etc. Three soap factories have a combined output of 80 tons a month; the coir fibre, rope and matting industry is found in the coconut districts; and a certain amount of pottery is produced. The value of imports decreased from £2,366,390 in 1918 to £1,934,169 in 1919, and that of the exports increased from £2,133,597 to £2,444,011, cloves and copra being largely responsible for the increment.—(*Col. Rep.—Ann.*, *No.* 1052, *Dec.*, 1920.)

Foreign Trade of the United Kingdom in 1920.—The following statistics show the value of the foreign trade of the United Kingdom in chemicals and related products during the year 1920, based upon the pre-war values of 1913:—

	IMPORTS RETAINED.					EXPORTS OF U.K. PRODUCE				
	Declared Values.		Values in 1920 estimated at average values in 1913.	Percentage excess of average values in 1920 over those of 1913.	Percentage deficiency (—) or excess (+) of quantity in 1920 compared with those of 1913.	Declared Values.		Values in 1920 estimated at average values in 1913.	Percentage excess of average values in 1920 over those of 1913.	Percentage deficiency (—) or excess (+) of quantity in 1920 compared with 1913.
	In 1913.	In 1920.				In 1913.	In 1920.			
	£1,000	£1,000	£1,000	Per cent.	Per cent.	£1,000	£1,000	£1,000	Per cent.	Per cent.

REVIEWS.

ORGANIC MEDICINAL CHEMICALS. *By* M. BARROWCLIFF *and* FRANCIS H. CARR. *Industrial Chemistry Series, edited by* S. RIDEAL. *Pp.* xvi.+331. *(London: Baillière, Tindall and Cox.* 1920.) *Price* 15*s. net.*

In taking stock of the literature dealing with chemical industry, it is somewhat remarkable that the oldest branch, that relating to the manufacture of drugs, should be so scantily represented. One reason is undoubtedly the fact that the subject is complicated, an immense variety of substances of different classes having to be considered; another, that the operations performed are on a relatively small scale and perhaps hardly appeal so much to the technical man as the larger industries, heavy chemicals, tar distilling, or even the manufacture of dyestuffs. Indeed, when one deals with many of the synthetic drugs, one is forcibly reminded that their economic manufacture should be carried out in conjunction with the dye industry; the very trade-mark "Aspirin" is the property of the Farbenfabriken vormals Friedrich Bayer and Co.

The appearance of the work now under review is all the more welcome since its authors have been successfully associated with some of the largest British works engaged in the manufacture of drugs, whilst their reputation as scientific chemists is such as to guarantee the absence of slavish reprinting of antiquated processes or the unqualified acceptance as gospel of all the statements made in patent specifications.

One paragraph in the authors' preface may well be commended to those engaged in the industry, namely, that relating to the supply of important synthetic chemicals during the war and the lack of economic basis on which such supply was established. In many cases this could not be helped at the time, but now that the war is over and the desire to retain the young industry in the country is a very real one, "it is of outstanding importance to perfect processes so that the most economical methods are used and the best possible yields obtained." If the directors of chemical firms were generally as well-versed in chemical knowledge as the authors, the desirable result would be attained more rapidly.

The Introduction, occupying only six pages, is apt and interesting. The subject matter is divided into sections arranged according to the uses of drugs rather than to their chemical relationships. This division has many advantages, but it cannot always be strictly adhered to, as is apparent when we turn to the natural alkaloids.

Narcotics and General Anæsthetics form the subject matter of the first section. Ether is dealt with at considerable length, and a good account is given of the manufacture as carried out at H.M. Factories at Pembrey and Gretna. Several diagrams illustrate the beautiful Barbet plant which succeeded in giving 94·3 per cent. of the theoretical yield during a period in which over 5000 tons of ether was manufactured. Following ether, we find methylal, paraldehyde, acetophenone and the simpler halogenated aliphatic compounds dealt with, whilst the section concludes with an account of the sulphone hypnotics and urea derivatives such as adalin and veronal.

Section II., dealing with Naturally Occurring Alkaloids and their Derivatives, is illustrated by several diagrams and is followed by Section III., in which an account is given of Natural and Synthetic Local Anæsthetics: one could wish that more than 24 pages could have been spared for an account of the interesting and varied compounds included. Antipyretics and Analgesics follow in Section IV., and here, as in the preceding section, one is struck by the diversity in structure of the compounds used to produce very similar physiological results.

In the case of Organic Antiseptics and Disinfectants (Section V.), phenol, other phenolic compounds and derivatives are taken first. The order followed is rather difficult to understand, for tribromophenol is separated from other phenolic compounds by an account of substances of the type of Chloramine-T: presumably the idea is to keep halogenated compounds together. After formaldehyde and hexamine, certain dyestuffs-antiseptics are dealt with, and the section finishes with the consideration of tannic acid and santalol derivatives.

Purgatives form the subject of Section VI., and Vaso-Constrictors and Vaso-Dilators of Section VII., a considerable amount of attention being paid to synthetic tyramine, histamine and adrenaline. Section VIII., dealing with Diuretics and Uric Acid Solvents, will prove very interesting to many organic chemists even if the subject is not as topical as that of the next section (IX.), viz., Organo-metallic Compounds.

Section X. gives an account of the digitalis group, skin irritants, glucosides and neutral principles, whilst pituitary and thyroid extracts, vitamines and other substances of interest, not finding any other place in the book, are dealt with in the eleventh and concluding section.

In a new edition, one or two rectifications will doubtless be made. On p. 188, Proflavine is described as 3:6-diamino-acridine sulphate, and on p. 190 Acriflavine is oriented 2:6. According to the system adopted in numbering the acridine ring, both should be 3:6 or 2:8, though the latter is now more commonly used. On p. 294, thiosinamin is referred to in brackets as allyl thiocarbamate, whilst the formula given is that of allyl thiocarbamide.

The book is written in an interesting manner and is well indexed; the printing and diagrams are clear; and as a guide to a good general knowledge of organic medicinal chemicals the work may be warmly recommended.

J. T. HEWITT.

THE YEASTS. *By* A. GUILLIERMOND. *Translated and revised by* F. W. TANNER. *Pp.* 424. *(New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.* 1920.) *Price* 33*s. net.*

In 1912 Professor Guilliermond contributed to the Section of Cryptogamic Botany of the *Encyclopédie Scientifique*, edited by Dr. Toulouse, a volume entitled "Les Levures," which forms the basis of the work under review.

So great has been the progress made in the domain of microbiology during recent years that Dr. Tanner of the University of Illinois, who had undertaken the English version, realised that it would be necessary to revise that which had been written, and to add much new matter, in order to produce a book adequate to the needs of those for whom it was originally intended. From the preface one gathers that the translator has been responsible for the revision of the chapters dealing with the physiological side of the subject, whilst the task of the original author has been that of bringing up to date the chapters on Morphology, Phylogeny and Description of Species.

Prof. Guilliermond is so well known for his investigations in this department of mycological science that his name is a sufficient guarantee that the more purely descriptive part of the subject has been dealt with adequately and well, and such will be found to be the case. The author has, in fact, placed all zymotechnologists (it is to be hoped that the exceedingly objectionable word "fermentolo-

gist" will not be adopted in this country) under a great debt of gratitude, and his book supplies a want which has been long and widely felt for a complete and descriptive list of the yeasts and associated budding fungi.

The system of classification adopted is that of Hansen, with some modifications and extensions. The family of the *Saccharomycetes* is divided into no less than fourteen genera, together with a number of sub-groups, but some of the points of differentiation are very slight and it is doubtful whether such an elaborate system is, in the present state of our knowledge, really justified.

It may be said here that the invariable use, by the translator, of the word "yeast" as the English equivalent of the more general French term "*levure*" is unfortunate, since it is sometimes used correctly to designate the true *saccharomycetes* and at other times, incorrectly, to cover the whole family of budding fungi, including those which do not form ascospores. This is a serious defect and one liable to produce much confusion in the minds of those whose acquaintance with the subject is limited. To such an extent is the misuse of the word "yeast" carried that in the bibliography a paper by the writer of this review is actually incorrectly quoted, the word "yeasts" having been inexcusably substituted for the word "torulae."

Whilst the descriptive portion of this work leaves little to be desired, the more general portion is very unequal and sometimes very disappointing. The plan is ambitious, but one cannot help feeling that too little care has been devoted to the critical selection of material, and the general impression produced by some of the sections is that of a loosely-constructed dictionary article, rather than that of a carefully thought-out contribution to an important monograph. In the section on the influence of oxygen on fermentation, we are told that Pasteur's conclusions have not been invalidated up to the present, and no reference is made to the work of Adrian Brown either in this section or in that describing the use of the "haemocytometer" (haematimeter). In the bibliographical index, however, Adrian Brown's papers on the subject are included, but under the name-heading: "H. T. Brown"!

A good many glaring mis-statements occur in this portion of the book. Thus, on page 3, we meet the truly amazing statement:—"True yeasts never roduce endo- or ascospores," whilst, a few pages iter, we read of: "the true yeasts producing endopores." On page 163, the word "estimating" hould be "detecting," and on page 124 the substiution of the word "alternation" for "attenuaion" destroys the sense of the paragraph.

Making all allowance for transatlantic spelling, he translation leaves much to be desired, and rrors of spelling are so frequent, especially in the ase of proper names, that attention cannot even e called to all those which have met the writer's ye during a cursory survey of the book. The ollowing, however, may be given as instances:—'Leewenhoek," "Mitscherlick," "Boullinger," 'Du Claux," and "Schutzemberger;" and among ther instances of careless proof-reading, reference nay be made to "galactoce," "hydrogen sulfur," 'guaiac," "hydriotic acid" and "ciniferin."

The use of the word "levulose" is etymologically njustifiable, and the use of the word "scum" for 'film" is quite unusual and also less exact. The ranslator, moreover, uses the word "hydrocarbon" n one whole section, instead of "carbohydrate."

The grammar often leaves much to be desired, nd not a few of the sentences are involved and adly expressed.

With all its faults, however, both of omission and ommission, the book will be of great value to the fermentation expert, as well as to the student of general mycology. It is because it is likely to be so valuable and because it possesses such excellent features that the reviewer has felt the necessity of calling attention to defects which can easily be remedied in future editions, and which at present detract somewhat seriously from the usefulness of an otherwise admirable publication.

A. Chaston Chapman.

The Chemistry of Enzyme Actions. *By* K. George Falk. *American Chemical Society Monograph Series. Pp.* 136. (*New York: The Chemical Catalog Co.* 1921.) *Price* $2·50.

The unanimous desire of Anglo-Saxon chemists to emancipate themselves from the influence of German chemical literature and its subtle propaganda has caused a good deal of thought and work to be devoted to the development of chemical literature in the English language. In this connexion special reference may be made to the praiseworthy pioneer efforts of Mr. F. W. Atack and his associates, which at least have had the practical result that the question was one of the subjects of discussion at the Inter-Allied Conference of Pure and Applied Chemistry at its meetings in London and Brussels in July, 1919. It was then agreed that the American Chemical Society, which, it may be remarked, is the sole body representing American chemists, should undertake the preparation of scientific and technological monographs.

With commendable celerity, in which one may be allowed, perhaps, to trace the influence of such hustlers as Dr. C. Herty and Dr. C. L. Parsons, the first of these volumes has now been produced in barely eighteen months from the inception of the scheme. The necessary arrangements for publication have been in the hands of certain gentlemen acting as trustees, and, in particular, of William A. Noyes and John Johnston, acting as editors respectively of the two series. The reviews are intended to present the chosen topic in a readable form intelligible to the general chemical reader who may be engaged in other lines of research, and at the same time to stimulate further research in the particular field. They are thus on the same lines as the monographs originated some years ago by Dr. R. H. A. Plimmer in this country and extended under the progressive auspices of Messrs. Longmans, Green and Co. It is generally admitted that the work done by the writers of the British monographs has been of the highest value to their fellow-chemists, and we may expect the same result from the labours of our American colleagues. Chemical science is to-day so vast, and its literature so complex, that no text-book of the old type can deal adequately with it, and it is only by the study of suitable monographs that the advanced student of the present day can gain the necessary all-round acquaintance with his subject. At a time when so much is made of specialisation it is worth while inserting a special plea for the necessity of the widest possible reading of chemical literature, so as to gain a sound knowledge of the subject. No one of us knows at the end of his university career in which particular sections of chemistry his life-work will be planned, and it is only by the broadest possible reading that the necessary critical faculties can be trained.

Dr. Falk's own work on enzyme action is well known and guarantees his competence to inaugurate the series. Broadly speaking, enzymes may be considered from three somewhat different points of view—chemical, biological, or mathematical, using this term to connote, in the author's words, "the better understanding of the fundamental chemical relations underlying an exact knowledge of chemical reactions"; it is mainly on these lines that the review is compiled. Accordingly,

the first part of the work deals with the more recent theories of chemical structure, the velocities of chemical reactions and their general theory, before specific reference is made to certain reactions catalysed by enzymes. Sections on the physical and chemical properties of enzymes lead up to a discussion of the chemical nature of certain enzymes and the mechanism of their action. A final section is devoted to their uses and applications. The whole work forms a somewhat abstruse review of present-day physico-chemical theories and will repay the closest study by those interested. It obviously invites criticism in detail, for which this is not an appropriate medium. Sufficient has been said to indicate the scope of the work and to wish the scheme every possible success on behalf of the English-speaking chemists on this side of the Atlantic.

E. F. Armstrong.

OBITUARY.

WILLIAM ODLING.

The death of Professor Odling, at Oxford, on February 17, in his ninety-second year, removes one who was closely associated with the earliest attempts to lay the theoretical foundations of our science. The name of Odling, together with those of his contemporaries, Williamson, Frankland, Kekulé, Berthelot, Wurtz, and others will live in the history of chemistry for his important contributions to the development of the theory of chemical types, which was originated by Gerhardt, who was inspired by Laurent. Odling also contributed a notable paper "On the Natural Groupings of the Elements" (Phil. Mag., 1857), which contained one of the first attempts to classify elements in accordance with "the totality of their characters." His best-known literary work is his translation of Laurent's "Chemical Method: Notation, Classification, and Nomenclature" (1855), but he was also the author of several text-books and lectures at the Royal Institution and elsewhere. His experimental researches related mainly to the composition of simple organic compounds, the ammonia compounds of platinum, the properties of indium, and aluminium compounds. In later years he investigated various potable waters, publishing in 1886, with W. Crookes and C. M. Tidy, a report to the Huddersfield Corporation on the action of water on lead, and serving as one of the analysts of the London water supply. At the banquet given by the Chemical Society, in 1898, to celebrate the jubilee of six of its past-presidents (among whom was Odling), the president (Prof. J. Dewar) remarked that Odling's work "was characterised by precise and clear ideas, and an almost forensic ability for putting things in a straight, concise, and unembarrassing manner."

Odling was born at Southwark in 1829; he studied medicine and graduated at London University, but work with Gerhardt at Paris led him to take up chemistry, and on returning to this country he became demonstrator in chemistry at Guy's Hospital at the age of 21. In 1850 he was appointed lecturer at St. Bartholomew's, and in 1868 succeeded Faraday as Fullerian professor of chemistry at the Royal Institution. Four years later he was appointed Waynflete professor of chemistry at Oxford, in succession to Sir B. Brodie. His connexion with the Chemical Society dated from 1848, and he served it as secretary from 1856 to 1869, and as president in 1873-74. He was made Fellow of the Royal Society in 1859, and doctor of mathematics and physics by the University of Leyden in 1875.

DANGEROUS DRUGS.

The hubbub which has arisen in connexion with the Dangerous Drugs Act is an example of the futility of allowing lay officials to deal with a highly technical subject, and has been aggravated by contemptuous refusals to accept the advice of competent authorities. The draft Regulations issued by the Home Office for the working of the Act are so impracticable and display such ludicrous ignorance of the actual conditions obtaining in medicine and pharmacy that they have aroused the ire and scorn of medical men, veterinarians, pharmacists, and the general public alike.

The inception of this Act "to regulate the importation, exportation, manufacture, sale, and use of opium and other dangerous drugs" was due to the need of giving effect to the International Opium Convention signed at The Hague in 1912. By the Treaty of Versailles (Article 295) Great Britain was pledged to bring the Convention into operation within twelve months of the coming into force of the Treaty. There was no serious opposition to the passing of the Act, the principle being accepted by all concerned as wholesome legislation. In the Committee stages of the Bill in the House of Commons several alterations were made mainly as a result of the informed criticism of Mr. W. J. Uglow Woolcock, general manager of the Association of British Chemical Manufacturers, who was formerly secretary to the Pharmaceutical Society, and able to speak with authority

The Act eventually came into force on September 1, 1920, and besides restricting or prohibiting (except under licence) the import and export of raw opium, prepared opium, and cocaine, it controlled the manufacture, use, and distribution of cocaine, morphine, ecgonine and diamorphine (heroin), and of preparations containing any of these. The real trouble began with the issue, early in January, of the draft Regulations. These were so drawn as to make it illegal to sell without a doctor's prescription such ordinary household remedies as cough mixtures (containing morphine or heroin in medicinal quantities), chlorodyne (containing morphine), or even gall-and-opium ointment. Twenty-five official preparations in the British Pharmacopœia are thus prohibited, as well as hundreds of unofficial preparations at present in daily use. The Regulations go far beyond the requirements of the International Opium Convention, which expressly recognised existing laws and regulations and laid down that nothing should "apply necessarily to medical prescriptions and to sales made by duly authorised pharmacists." The retail sale of all the drugs mentioned in the Dangerous Drugs Act is already subject to very strict control by qualified pharmacists under the Poisons and Pharmacy Acts. In addition to previously existing restrictions, however (of which the official draftsmen were apparently entirely ignorant), these Regulations provide for five separate books to be kept by pharmacists and four by doctors or veterinary surgeons, in which records of sales, etc., have to be kept.

Pharmacists were promptly up in arms as soon as the Regulations were issued, and when it dawned upon the medical profession that a policeman might enter a doctor's surgery and overhaul his stock of morphine preparations, etc., in a vain endeavour to trace the whereabouts of a minim of hypodermic solution of morphine, and that every doctor would have to keep a separate record of each issue of morphine, cocaine, opium, and diamorphine the medical temper likewise began to rise. Furthermore, when it was discovered that no farmer or flock-owner could keep a colic draught for his cattle, that no householder could store laudanum, Dover's powder, or gall-and-opium ointment in his medicine cupboard, the outcry against this inept Departmental legislation developed to such an extent that it has induced a gradual and progressive "climbing down" on the part of officialdom. What the ultimate result will be it is difficult to gauge, but the situation at present is that the Home Office autocrats in charge have turned down the commonsense suggestion that the Regulations should be referred to a committee of medical and pharmaceutical experts for consideration as a whole.

VITAMINS AND THE FOOD SUPPLY.

A. HARDEN.

It is now well recognised that a satisfactory diet must not only contain a sufficient supply of energy along with a provision of protein and mineral substances, suitable both qualitatively and quantitatively for the needs of the organism, but that it must also furnish certain hitherto unidentified accessory factors, the so-called vitamins, required, it is true, only in minute quantity, but indispensable for growth and proper maintenance. Three of these principles have so far been differentiated, and these are most conveniently termed, adopting Drummond's modification of Funk's nomenclature, vitamins A, B and C. The evidence on which the belief in the existence of these three essential dietary factors is based is by this time familiar and can be found in many quarters (see especially Report of the Committee on Accessory Food Factors, Special Report Series No. 38, M.R. Council, and Physiological and National Needs, Constable).

Two important points must, however, be borne in mind throughout any discussion of the vitamin question. *First*, that the mammalian organism is unable to synthesise these principles for itself and is entirely dependent for its supply on the food with which it is nourished; *second*, that the young growing organism requires a relatively greater supply of them than the adult. It must further be remembered that the offspring is in its early stages entirely dependent for its nutrition upon the mother, who has therefore to receive a supply of vitamins adequate for the needs both of herself and her young.

The distribution of these factors among the common articles of diet of man and the domestic animals is being gradually worked out and is already known in its general qualitative relationships, but requires a large amount of further quantitative investigation. The table overleaf will serve to remind the reader of the specific importance of each of the vitamins and to give a rough idea of the kind of food material in which it may be expected to be found.

Vitamin Requirements.

When we come to consider the vitaminic requirements of an average individual we have to confess to a lamentable lack of accurate information. We are, indeed, in a better position with regard to many of the lower animals, for it has become possible to ascertain with some degree of accuracy by direct experiment the amount of milk or orange juice necessary to protect a guinea pig or a monkey from scurvy, or the amount of yeast which will perform a similar function for a rat or pigeon with regard to polyneuritis. One important conclusion which has been definitely ascertained in this respect is that different animals, even although closely

related, vary very considerably in their need for vitamins. A striking instance is afforded by the guinea pig and the rat, both rodents, in relation to the antiscorbutic vitamin. The guinea pig is very sensitive to lack of this principle and on a scorbutic diet rapidly shows symptoms of scurvy and finally dies of the disease. The rat on a similar diet shows scarcely any sign of the absence of the principle, grows to a good weight and produces young. Careful examination has, indeed, revealed a certain inferiority in the scorbutically fed animals, but scurvy never develops. A less extreme difference is shown by a comparison of the antiscorbutic needs of the guinea pig and the monkey, animals which are both affected by scurvy. The latter, of about ten times the weight of the former, requires almost exactly the same amount of antiscorbutic (orange juice or milk) to protect it from scurvy.

With regard to human requirements we are compelled to turn to a consideration of the actual diets which have been found to keep us in health and draw what conclusions we can from an analysis of these. Except in the case of the very young, these diets are generally of a mixed and varied character so that accurate deductions are difficult. Reference to the table will show which constituent of the daily diet must in most cases be the source of each of the vitamins. As regards the child we are in a somewhat better position. The antiscorbutic requirements (as well as those of vitamins A and B) of a child of 5—7 kilos. are usually considered to be met by a diet of about 500 c.c. of cow's milk. Although, as we shall see, milk is itself a variable quantity, and the above amount is not strictly a minimum, this affords a basis for a rough comparison with the monkey and guinea pig, which both require 100 c.c. of milk daily.

Variation in the Vitamin Content of Foodstuffs.

It is almost certain that the amount of vitamin contained in natural foodstuffs is not a constant quantity, but varies under different conditions of season, age, and so forth. Very little accurate work has yet been done in this direction, but indications have been observed, for example, that the antiscorbutic potency of grass is greater in the young than in the more mature growth. An extreme case is afforded by the well-known production of the antiscorbutic vitamin during the germination of seeds, which themselves contain none, or very little, of this principle.

When we come to deal with secondary foodstuffs—derived from animal sources—a further complication arises, which is well illustrated by the case of milk. The vitamins of the tissues of the animal which is secreting milk are all derived from the foodstuffs of the diet. If these are varied so that very little vitamin is supplied in them several possibilities arise. The supply of milk may be kept up but its vitamin content may be diminished, so that the young suffer, or the vitamin content may be maintained for some time at the expense of the tissues of the mother. On the other hand, the difficulty may be met by a smaller secretion of a milk of the original quality. Here, again, the experimental observations are not conclusive. Hopkins, at Cambridge, found that the fat-soluble factor (vitamin A) of goat's milk remained approximately constant when the animal was given a diet deficient in that respect, but that the quantity yielded fell off. On the other hand, in America, several investigators

TABLE I.

	Vitamin A.	Vitamin B.	Vitamin C.
Synonyms	Fat-soluble A	Water-soluble B Anti-neuritic	Water-soluble C Anti-scorbutic
Effect of deficiency..	Retarded growth ending in death Eye-disease (Keratomalacia) Probably one factor in causation of rickets	Retarded growth ending in death Beri-beri Polyneuritis of birds, rats, etc.	Scurvy
Chief sources ..	Animal fats Fish liver oils Green vegetables Egg-yolk Butter and milk Oleo-margarine, in proportion to animal fat.	Seeds, particularly in the germ, pericarp and aleurone layer Yeast Egg yolk	Green vegetables (especially *Cruciferae*) Orange and lemon juice Tomatoes Germinated seeds Swedes and turnips
Present in smaller amounts.	Oil-seeds Carrots	Meat Milk Potatoes and some other tubers and roots Green vegetables Some fruit juices	Meat Milk Potatoes and some other tubers and roots Many fruit juices Dried vegetables
Absent from ..	Most vegetable oils Most lard Most margarine White bread Egg white Yeast Purified proteins and carbohydrates	White bread Polished rice Fats Egg white Purified proteins and carbohydrates	Seeds White bread Fats Yeast Purified proteins and carbohydrates

orking with cows found only a small diminution in ie milk flow, but a large depreciation in the anti-orbutic potency of the milk, when the cows were ven a diet deficient in vitamin C. Indications ive, moreover, been frequently observed of the itiscorbutic inferiority of winter to summer milk, id the winter feed given to cattle in this country frequently very deficient in both vitamins A and . At this point laboratory investigations come ito close contact with practice, and it should not difficult to devise a winter feed for cattle which ould ensure a supply of milk containing as much the various vitamins as that produced during ie summer. Precisely similar conditions hold for iman mothers, and there seems little doubt that ck of sufficient vitamin in the diet of expectant id nursing mothers is often responsible for ill-ialth or positive disease in their children, such as ckets and scurvy—obvious or incipient—with all ieir evil and lasting results. It is, moreover, ivious that the vitamin content of many im-ortant foodstuffs, such as butter, meat, animal ts, etc., must be dependent on the diet of the iimals from which they are derived.

Influence of Processes of Manufacture or Preparation.

We have so far considered foodstuffs in their itural state, but to the variations inherent in the iture of the different food materials or due to odifications of the diet of animals, must be added iose brought about by the treatment which many odstuffs receive before they reach the consumer.

Milling of Grain.—The classical example of this the milling of grain (rice, wheat), in which the irm, or embryo, which contains by far the greater irt of the vitamin B and most of the pericarp and eurone layer, which contain the rest, is removed. i is now well known, the unbalanced use of milled ce leads to beri-beri, and is the main cause of that sease in the tropics. In the same way the British ldiers during the siege of Kut suffered from beri-ri on account of the lack of vitamin B in their et of white bread and meat, whereas the Indian oops escaped this scourge because their ration in-ided a kind of lentil (rich in vitamin B), and their ead was made from a less "perfectly" milled ain. It is interesting to note, in passing, that regards scurvy the conditions were reversed. In e total absence of raw vegetables and fruits the itish were protected by their large ration of rseflesh; the Indians, who refused to eat meat, nt down with a scurvy.

Desiccation.—The effect of drying varies very eatly with the nature of the food material. bbage, the richest known source of the anti-rbutic vitamin, when dried, even at a low tem-rature, loses 70 to 80 per cent. of its antiscorbutic ency, and similar results are given by many er vegetables. On the other hand, fruit juices ange, lemon) can be evaporated *in vacuo* with le or no loss. About milk some uncertainty pre-ls. Fresh cow's milk is a very poor antiscorbutic, nly about 1 per cent. the value of raw cabbage, , moreover, as has been already emphasised, ies in character with the diet of the cow. The ency of dried milk depends in the first instance the process employed for drying, and there ns little doubt that if undue exposure to a high perature (and possibly to aeration) is avoided, d milks can be prepared not greatly inferior in scorbutic potency to fresh milk. On the other d, it has been definitely proved by experiments monkeys (and guinea pigs) that many samples ried milk actually put on the market contain h less of the antiscorbutic principle than fresh . So markedly is this the case in some in-ces that an animal which has acquired scurvy certain ration of dried milk has been cured by qual ration of fresh milk. Vitamins A and B, on the other hand, are comparatively less affected by desiccation, although here, again, the effect varies with the nature of the foodstuff. Thus, milk appears to suffer very little loss in either of these respects on drying, whereas cabbage loses a large part of its vitamin A on drying, although not so high a proportion as of the antiscorbutic.

Preservation.—Comparatively little is known of the effect of preservation on the vitamin content of food materials. The most accurate information available concerns the antiscorbutic factor. Dried cabbage has been carefully tested in this respect by Holst, who has found that when it is air-dried and preserved over phosphorus pentoxide the anti-scorbutic potency (which, it must be remembered, is only a small fraction of that of fresh cabbage) is retained even at 37° C. for long periods. When preserved over calcium chloride, however, it rapidly deteriorates, and more rapidly as the temperature at which it is preserved is raised. Dried orange juice, too, has been found to retain its potency over considerable periods, and it seems probable that a perfectly dry powder will withstand pre-servation at ordinary temperatures for a long time, whereas in the presence of even very small amounts of moisture deterioration will occur. Lemon juice under ordinary conditions rapidly deteriorates, but in presence of the natural antiseptic provided by the oil of the rind has been kept for as long as two years at ordinary temperature, whereas at 37° C. in the same time it became quite inactive.

Heat.—The action of heat on the vitamin content of foodstuffs is, of course, of fundamental import-ance, since many of the processes of food prepara-tion and preservation involve the application of heat at some stage. The experimental investiga-tion of the question has been complicated by the fact, which at first escaped observation, that cer-tainly in the case of the fat-soluble vitamin A, and probably in that of the antiscorbutic C, aeration plays an important part as well as rise of tempera-ture. It has so far been found that vitamin A is moderately stable towards rise of temperature, provided that the presence of air is avoided, whereas in the presence of air it is rapidly inacti-vated even at comparatively low temperatures. Thus, butter-fat heated at 120° C. in an autoclave for four hours was found still to contain abundance of vitamin A, whereas when it was simultaneously aerated by a current of air it lost the whole of its potency in the same time. This loss on aeration has also been found to occur in six hours at as low a temperature as 50° C. Cabbage retains practically the whole of its vitamin A on cooking, and milk, like butter, can be autoclaved at 120° for an hour without its value in this respect being perceptibly impaired. With regard to the antiscorbutic vitamin, matters are not quite so clear. The effect of heat seems to depend largely on the nature of the material in which the vitamin occurs. Thus, cabbage juice rapidly loses a large proportion (about 85 per cent. of its potency) when heated for an hour at 100° C., whereas swede juice only loses 50 per cent., and orange juice (even when neutralised) is unaffected under the same conditions. Whether aeration is concerned is not yet definitely settled. In milk the antiscorbutic vitamin is certainly less stable than vitamin A, since autoclaved milk is free from antiscorbutic, but contains a considerable amount of vitamin A. Vitamin B (the anti-neuritic) must be regarded as moderately stable towards rise of temperature, since it has been found to be little affected by heating for 1—2 hours at 100° C. (wheat embryo, yeast extract), and has even been known to survive boiling with sulphuric acid (Funk).

The practical conclusion as regards processes of sterilisation is that at present it is unsafe to dogmatise, particularly with regard to the anti-scorbutic vitamin, so that each new case really re-

quires special investigation. It is already known, for example, that the process of canning largely destroys the antiscorbutic value of green vegetables, whereas canned tomatoes retain a large part of the high activity of the fresh fruit.

Oils and Fats.—Particular interest attaches to the presence of vitamin A in oils and fats because these are constituents of all diets and, moreover, form in many cases the chief, if not the only, source of this vitamin. Almost all animal fats have been found to contain this substance, the striking exception being lard. As this question has recently been brought before this Society by Drs. Drummond and Zilva, it will suffice to state that this exceptional deficiency has been found by them to be in part due to the processes of extraction and refinement and in part to the peculiar relation of the pig to this vitamin. Fish oils are very rich in vitamin A, but it is thought that much is lost in the processes of refining. Hydrogenation absolutely destroys this vitamin, hydrogenated whale oil, for example, being absolutely devoid of it, whereas the natural oil is rich in it. Whether this is due to the actual reduction, to the catalyst, or to the conditions prevailing during the treatment is not yet known.

The vegetable oils form a problem of great importance in this respect. Most of the oil-seeds contain more or less of the vitamin, whereas many of the vegetable oils as placed on the market, and used for the preparation of margarine, are devoid of it. Whether this is due to the small proportion present in the original seed, to the process of extraction or to the subsequent treatment of the oil is not definitely known. Further investigation is urgently called for to settle these important questions. Much has been already done at the initiative of the manufacturers, and thanks to the wise liberality of the Medical Research Council, which has devoted large sums to the support of investigations on the vitamins, steps are now being taken to make a systematic study of this subject, which has so vital a bearing on the health of the population in general and of the child population in particular.

FILTRATION BY ROTARY VACUUM-FILTER.

F. BLOOR.

At the Conference on Filtration held last July by the Chemical Engineering Group little attention appears to have been given to filtration by rotary vacuum-filters, although one would gather from the remarks of E. Hatschek (*cf.* J., 1920, 227 T) that, owing to the accessibility of the cake, whereby both washing and removal are facilitated, and the fact that the filtering process can be made continuous, the method would be one in fairly general use in the chemical industry. However, except for a few products, such as soda ash, produced on a large scale, and its use for extracting salt from ammonium sulphate, the rotary vacuum-filter seems to find little favour at present among technical chemists.

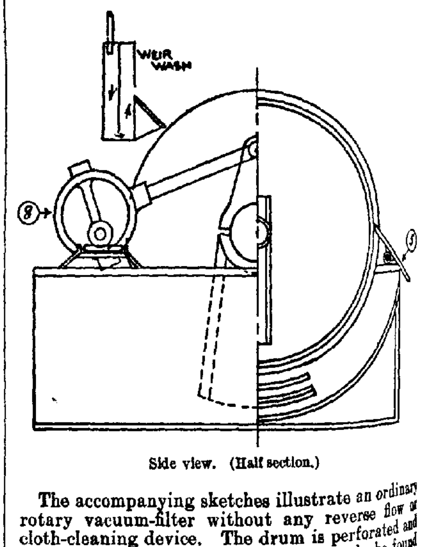
In a recent issue of the *Chemical Trade Journal* (Vol. LXVII., p. 741) a chemical manufacturer writes:—" I have cut my filtration costs down from £3 to 1s. 9d. per ton by the use of continuous automatic filters." Although the type of filter is not stated, the inference to be drawn is that the enormous saving in labour costs has been brought about by the substitution of a continuous filter (such as the rotary vacuum-filter) for a neutch or filter press. It is the possibility of this saving in labour charges and the belief that objections to this type of filter are ill-founded which induce the writer to advocate its more extensive use.

As illustrating the low labour costs which are possible with a rotary filter, one may instance the case of a filter with a drum 6 ft. in diameter by 3 ft. 4 in. wide discharging 6 to 8 tons of soda ash per hour at a labour cost of less than 6d. per ton; moreover, for this cost the material is deposited (by a belt-conveyor) at any desired spot. The question for the chemical manufacturer is, however, whether this type of machine can fulfil the necessary filtering desiderata when dealing with products that differ from soda ash (for instance, in the filtering and washing of sludges, amorphous substances, dyestuff-intermediates, as well as dyestuffs themselves), and can give better results at less cost than neutches or filter presses. In the opinion of the writer this type of filter can be made to deal efficiently with substances of the kind mentioned.

The superiority of the rotary vacuum-filter over other types of filter can obviously only be demonstrated by actual filtration tests on the products concerned, and after comparing filter capacities, costs, efficiencies (washing, etc.). The writer has carried out a few tests with this object in view, but the filter was the ordinary type (described below) without the improvements suggested. However, by measuring the thickness of cake which could be built up and the speed of rotation, it was possible to estimate fairly accurately what a suitably designed rotary filter could do.

The following are actual examples of two very dissimilar products:—(1) A light crystalline substance; cake built up $\frac{1}{2}$ in. thick, drum rotating 1½ revolutions per minute. (2) Sludge (very sticky); cake built up $\frac{1}{8}$ to $\frac{3}{16}$ in. thick, drum rotating ½ revolution per minute. This cake gives great trouble in washing in a wash-press, but was washed efficiently on the rotary filter.

With a filter of the size already indicated it should therefore be possible to filter and wash products similar in nature to the first at the rate of 5 to 6 tons an hour, whereas with sticky material the rate would of course be much slower. The rate for a sludge (which is a difficult substance to filter) would be about one ton per hour.



Side view. (Half section.)

The accompanying sketches illustrate an ordinary rotary vacuum-filter without any reverse flow or cloth-cleaning device. The drum is perforated and rotates at a suitable speed (this can only be found by experiment). Over the drum perforations is stretched a suitable filtering medium (cloth or wire gauze), which is secured to the drum by wire or stout cord. The axle of the drum is stationary and forms part of the vacuum system. By producing a

vacuum on the inside of the cloth, which is immersed in the reservoir, liquor is drawn through the filtering medium, leaving a film of solid on the cloth. When the drum is rotating this layer of solid can be washed with a suitable solvent (the washings being kept isolated from the filtrate, if necessary). It will be evident that this type of filter lends itself to the use of mechanical devices for drying or steaming the cake and also for dealing with fumes. Where the drum passes the "doctor," or knife, the solid is scraped off, and should then be in a form very suitable for handling at little cost.

requires very little knowledge of filtration to that the whole success of the filter depends on taining the cloth clean; otherwise the rate of ring will slow down to such an extent as to e the method valueless. In the case of a crysne body like soda ash the "doctor" is clear of cloth by about $\frac{1}{16}$ in., so that the cloth requires ning before it enters the liquid. This is easily mplished by causing a portion of the filtrate to through the cloth again (usually termed a re- flow). The filter will run continuously for days with very little attention, but with sludges (*e.g.*, from limed-out sulphonations) the problem is more difficult and cannot be solved as easily as for soda ash. The layer of sludge collecting on the cloth will be very thin ($\frac{1}{8}$ to $\frac{1}{4}$ in.), and the "doctor" and drum must be adjusted so accurately that practically all the solid can be scraped off without injury to the cloth. In addition, a very efficient cloth-cleaning device should be used, and the writer suggests that this is best achieved by designing the drum of the filter so as to leave the binding-wire or cord flush with the filtering medium, and providing an internal pressure chamber (designed for varying pressures of air or liquid) to keep the pores of the cloth clean. The absence of these last two factors has caused the rotary filter to be condemned as unsuitable for dealing with such materials as sludges and other products from chemical and dyestuffs factories.

Apart from the question of low labour costs, there is no doubt that the maintenance cost (filter cloths, repairs to power services, etc.) will be lower for a rotary vacuum-filter than for filter presses using compressed air and hand-scraped cloths. However, each filtering process is a problem in itself, and the best and most economical results can only be achieved by experimenting with all the available types of plant. In the past it is doubtful whether chemical manufacturers have given to the rotary vacuum-filter the consideration that its merits deserve.

AN INTERESTING FIRE IN A LABORATORY.

T. HOWARD BUTLER.

The following account of a fire, which took place in the laboratory of Messrs. Wm. Butler and Co. (Bristol), Ltd., will no doubt be of interest to members of the Society, as the circumstances were extraordinary, and may be of use as a warning to other chemists.

The diagram shows the apparatus that was employed for distilling coal-tar creosote oil. The still is the one recommended by the Ministry of Munitions, and used during the war by its advisors, Dr. H. G. Colman and Dr. P. E. Spielmann, for estimating the amount of benzene and toluene in tar. It will be noticed that the iron still is heated by means of a ring burner which completely surrounds the still, and which may be moved up or down as desired with the object of facilitating the distillation of a watery tar.

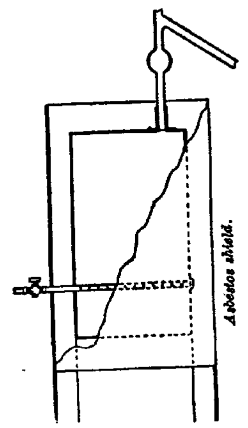
In the distillation in question the still contained about 0·75 gall. of creosote, to which had been added 200 c.c. of a heavy naphtha to facilitate distillation of the small quantity of water in the original creosote. The object of the distillation was to obtain a fraction of creosote oil distilling within a certain range of temperature.

The distillation had been carried out with the ring burner placed about three inches from the bottom of the still, and apparently all the water and naphtha had been removed, as the distillation had ceased. The flame of the ring burner had not been raised, and the contents of the still were "sweating," as it was desired to be sure that all the water had been distilled off. This "sweating" had been going on for some time, approximately one hour, and the temperature of the vapour at the top of the still during this time was 210° C., which indicated that the temperature of the liquid in the proximity of the burner was probably about 250° C.

At the time of the accident, fortunately, no person was in this laboratory, and the first indica-

tion of any trouble was given by a chemist who was passing the door and saw that the still was "bolting over." This person warned the chemist who was in charge of the distillation, and before either could get into the room, an increasing hissing noise, that can only be described as like a roaring wind, was heard. Both chemists rushed towards the room, which is about 21 ft. long, by 12 ft. broad, by 12 ft. high, and found it completely full of a thick black cloud.

Fortunately this laboratory was fitted with a stop-cock on the gas-main outside the room itself. This was immediately turned off, but there was a small quantity of creosote in a tray in the near vicinity of the still on fire. They removed this, together with some smouldering papers which were on the table in the centre of the laboratory. As the room was completely filled with this black smoke, and all apparent danger had ceased, the laboratory was left for several hours until the carbon had settled. The heat of the combustion or slow explosion, whichever it may be termed, was distinctly felt in the adjoining laboratory, although no serious concussion, beyond the already described "rushing wind" sound, was noticed.



Still, 6in. diam., 1ft. high.
Capacity, about 1 gall.
Charge, ½ gall.
Burner at time of explosion, 3in. from bottom.
Charge about 5in. from top.

The room was carefully examined the following day, and it was found that intense heat must have been developed during the accident, as a small part of the lead bench had been melted, and paint on the shelves and beams supporting the ceiling was badly blistered, also note books, papers, and similar articles lying on the table in the centre of the laboratory were completely charred; in fact, the appearance of the laboratory the next day gave the impression that a fire had been burning in the room for some considerable time; as a matter of fact, the actual fire lasted only some few seconds.

An interesting feature of the occurrence was that within two yards of the still there was a bottle containing about 100 c.c. of ether which remained unaffected.

It is not easy to determine definitely the cause of the accident, but it is probable that during the "sweating" process the top portion of the liquid became heated to a fairly high temperature, and that probably there was one or perhaps more drops of water condensed on the top of the still, which fell into this heated liquid and caused the "bolting." This may have become so violent that the cork was blown out of the still and ebullition again increased until there was a considerable cloud of creosote vapour above and around the still; and then this vapour was fired by the flame from the ring burner. It is conceivable that the cloud was in a condition of part vapour and part spray, and that when it caught fire it burned so rapidly that what might be termed a slow explosion ensued.

As the lessons that can be drawn from such an accident are of great value for future precautions, it may be of interest to observe that there is always a danger in heating any vessel to a comparatively high temperature at a point other than the bottom, unless the bottom be also heated; and in this case it seems probable that the accident would not have occurred if a small flame had been playing on the bottom of the still. This would have ensured the whole of the contents of the still being at one temperature. The superheating would probably not have been serious if the ring burner had been set nearer the bottom of the still. It is doubtful if "sweating" should be prolonged for any length of time; if the creosote had been heated more rapidly, immediately after the water had been distilled over, the rush of vapour would probably have brought over any small quantity of water that had condensed on the top of the still. Again, a ring burner should not be used without bottom heating, and it should be rapidly lowered to near the bottom of the still by the time that there are indications that all the water has been distilled over.

The above explanation and the conclusions drawn from it are put forward tentatively in the hope that others who have experienced similar accidents will also communicate their observations and inferences to this Journal.

SOCIETY OF CHEMICAL INDUSTRY.

JOINT MEETING WITH THE INSTITUTION OF MECHANICAL ENGINEERS.

A special meeting of the Society was held conjointly with the Institution of Mechanical Engineers—the first, it is to be hoped, of a series of similar meetings—at the Institution, Storey's Gate, S.W. 1, on March 4, when Monsieur Paul Kestner read a paper on "The De-gassing and Purification of Boiler Feed-Water." Capt. Riall Sankey, president of the Institution, was in the chair, and he was supported by Sir William Pope and other representatives of the two societies.

In the process continuous blowing-down of the boilers is combined with hot purification of the make-up feed water. The blow-down water is passed through a feed-water heater, the mud and separated salts are retained in a trap, and the purified blow-down water is returned to the boiler. When the feed-water, containing sodium carbonate and bicarbonate, gets into the boiler, the bicarbonate is decomposed and the carbonate partially hydrolysed, so that hydroxide, as well as carbonate, is used to purify the feed-water. The Kestner apparatus comprises a steam-separator, and a heater having a central reservoir to receive the blow-down liquid, and an annular vessel surrounding the reservoir, into which the purified blow-down water is decanted. The feed-water, preheated by the steam, mixes with the blow-down liquid as it leaves the reservoir, a measured amount of soda having been previously added, and precipitation and settlement take place in the annular chamber.

Dissolved oxygen is removed by means of cas iron containing 0·7 per cent. of manganese, whic acts as a catalyst. The hydrated ferric oxid formed is reduced to the ferrous state on being le in contact with the unchanged iron, and the ferro compound is available for further de-gassing. I the apparatus employed the water flows alternate through two vessels each initially filled with iro turnings, or it passes up and down a single vess similarly charged and with filters at each end, t direction of flow being changed by a valve-arrang ment, thus allowing the material to recuperate.

NEWS FROM THE SECTIONS.

GLASGOW.

A meeting of this Section was held in the Institute of Engineers and Shipbuilders, Glasgow, on February 1. Mr. J. H. Young occupied the chair, and Mr. J. G. Roberts read a paper on "Colloids in Clays: A Criticism."

The author gave a brief account of the better known colloids, typical suspensoids, and emulsoids of the silicic acid type. He described the composition and character of china clay, and contrasted its "colloidal" properties and those of other purer clays with silicic acid and alumina gels. The contradictory nature of many of the statements in Searle's paper on "Colloids in Clay" contained in the third Report on Colloid Chemistry were pointed out and discussed, and also the apparent confusion between the colloid and amorphous conditions. The liquefaction of clay suspensions was demonstrated, and also electro-osmosis or cataphoresis of a suspension of fine clay. Fired samples of some electrically-separated clays were also shown.

EDINBURGH AND EAST OF SCOTLAND.

At a meeting held on February 15 Dr. D. S. Jerdan in the chair, a paper was read by Mr. W. N. Stokoe, entitled "Investigations on the Rancidity of Margarine and Butter Fats."

After referring to the chemical changes possibly occurring in rancid fats, the author discussed the chief causes of rancidity, which in commercial oils are the action of air, light and moisture, and lipolytic enzymes. Rancidity in butter and margarine is caused by the action of micro-organisms which find in the substances suitable media for their growth and propagation.

Mr. Stokoe classified the various forms of rancidity under the divisions of appearance, odour, and taste, and showed lantern slides of the micro-organisms associated with each form. A particular kind of rancidity, which he termed the "perfume" form, occurs only in those margarines containing coconut and palm-kernel oils, and is caused by enzymes secreted by such moulds as *Penicillium glaucum* and species of *Aspergillus*. The substance giving rise to the perfume consists chiefly of methylnonyl ketone accompanied by other ketones. Other forms of rancidity were discussed and specimens of rancid fats exhibited.

The various sources of contamination by micro-organisms during the manufacture of butter and margarine were examined, and great emphasis was laid on the necessity for thorough cleanliness in manufacturing processes. The practice of transporting and storing oils and fats in wooden containers is utterly wrong, as it is impossible to sterilise the wood properly, and the canvas put on the bungs of barrels is a fruitful source of mould spores. The paper used for wrapping margarine also gives rise to contamination by micro-organisms, and the author described various methods of sterilising wrapping paper.

NEWCASTLE.

Two papers were read at the meeting held in Armstrong College on February 16, Dr. J. H. Paterson presiding, both of which described work carried out in the Agricultural Chemistry Laboratory of the College.

Dr. A. A. Hall described "A Quick Volumetric Method for the Estimation of Mercury," which is applicable to soluble mercuric salts either in the presence of acid or of any substance unaffected by caustic soda solution, and can also be used in the presence of soluble copper salts and ammonium salts. An excess of an ammonium salt and then an excess of the standard alkali is added to a known volume of the mercuric solution, and the "white precipitate" formed is made up to a known volume with water and filtered through a dry filter. An aliquot part of the filtrate is titrated with standard acid in presence of methyl orange, and the difference between the amounts of alkali and acid used represents the amount of alkali consumed in precipitating the mercury. If acid be present it can be estimated by titration with alkali before the excess of alkali is added. If the solution contains copper the deep-blue solution formed gradually fades as the liquid becomes neutralised. The author adduced analytical results which indicated the accuracy of the method under the various conditions mentioned.

In a paper on "Fractional Distillation Columns," Mr. S. Hoare Collins described a short fractionating column about 30 cm. long from bottom to side tube and 18 cm. diameter with an extension tube 90 cm. long of the same diameter. Both are filled with glass spirals made by winding heated glass rod of 5 mm. diameter round a central rod of 6 cm. diameter. Experiments conducted with a mixture of benzene and toluene showed that such a spiral gave far better results than a "rod and disc" filling.

MANCHESTER.

The sixth meeting of the session was held at the Textile Institute on March 4, Mr. Allan presiding. About fifty members were present and two papers were read. The first, on "Column Apparatus for the Chemical Industry," read by Mr. S. J. Tungay, set out the conditions to be observed in the design and construction of column apparatus, and emphasised the point that faulty working was in most cases due to disregard of the fundamental actions required to take place in the columns; as an instance it was mentioned that counter currents may mix or may not. The paper contained descriptions of many types of column apparatus. The second paper, on "Normal Amyl Benzene and some of its Derivatives," by Messrs. L. G. Radcliffe and N. Simpkin, was read by the former, and described investigations made to find uses for butyl alcohol now being produced in large quantity. The production of a mono-sulphonic-acid phenol and a para nitro-compound was described.

MEETINGS OF OTHER SOCIETIES.

THE INSTITUTE OF CHEMISTRY.

The forty-third annual general meeting was held on March 1 at Russell Square, W.C. Sir Herbert Jackson, the retiring president, in his address remarked that Government departments and official authorities generally had of late extended greater recognition to the services of men of science than in the past. The conditions of appointment of chemists, both in the Government service and in industry, had been improved, and until the close of 1920 very few members of the Institute were disengaged. The prevailing depression in industry had, however, affected the employment of chemists, but even now less than 50 were disengaged out of nearly 3300 on the roll. The by-laws of the Institute had been revised to provide for the representation of chemists from various parts of the country and practising in different departments of work, to define more specifically certain points relating to the ethics of the profession, and to restrict the membership of the Institute to British subjects. The Institute was taking part in many matters affecting the public life of the country where chemistry was concerned, and the annual report showed that chartered professional bodies of this

character were able to render valuable service to the State. It was probably desirable at the present moment for the Council of the Institute, without taking part in politics, to express its views on the grave importance of maintaining in this country industries on which not only the future development of our chemical industry and many allied industries depends, but the future of a very large number of students of chemistry who are now being trained. The Institute was entrusted by its charter to secure the supply of well-trained chemists, but unless a great chemical industry was maintained their prospects would be very poor. The president maintained that the Institute had throughout its existence fulfilled the purposes for which it was incorporated. It had kept alive the corporate spirit of the profession; it was the officially recognised public body to which the country could turn for advice and guidance on matters relating to the profession; it assisted those who intended to follow the profession of chemistry, and promoted and maintained the highest standard of training and competence for that profession; it registered the trained and competent, and it fostered the strictest integrity on the part of its members in their dealings with one another and with the public. He was confident that it would continue to gain strength and prestige.

SOCIETY OF PUBLIC ANALYSTS.

An ordinary meeting was held at the Chemical Society's Rooms on March 2, Mr. A. Smetham presiding.

A paper on "The Acidity of Ink and the Action of Bottle Glass on Ink" was read by Mr. C. A. Mitchell, who explained why acid was added to ink, gave the amount present in standard inks, and described acid-free inks, the estimation of acidity, and the difficulty caused by the presence of dyestuffs. The uses and limitations of the hydrogen-peroxide method and the estimation of total acidity as a check on the manufacturing process were dealt with and the effects of glass on ink discussed.

In a paper on "The Detection of Adulteration in Butter by means of the Melting-point of the Insoluble Volatile Acids," Mr. G. van B. Gilmour described how the addition of small amounts of coconut and palm-kernel fats to butter appreciably lowers the melting-point of the insoluble volatile acids. Tables of melting-points and distillation-figures for pure fats and mixtures were given, and also graphs showing how the melting-point is affected by adding increasing quantities of coconut and of palm-kernel fat.

Messrs. S. H. Blichfeldt and T. Thornley described a method and apparatus for routine determinations of melting-points of fat and fatty acids, in which a column of melted fat 1 cm. long in a tube of 1 mm. bore, 3 mm. diameter, and 60 mm. length, is rapidly solidified on ice and kept there for two hours; the tube is then placed in a water-bath with the upper level of the column 1 cm. below the surface, and heated at the rate of 1° C. per minute. The temperature at which the column rises is taken as the melting-point. The apparatus consists of a rectangular glass water-bath holding twenty tubes, which is heated, stirred, and illuminated electrically.

THE CHEMICAL SOCIETY.

At the meeting held on March 3, Sir James Dobbie presiding, the following papers were read in abstract:—(1) "The Chemistry of the Glutaconic Acids. Pt. XII. The simultaneous occurrence of 1:2- and of 1:3-addition to glutaconic ester. A study in mobile equilibrium involving the utilisation of the labile ester in the 'nascent' condition": C. K. Ingold and J. F. Thorpe. (2) "A Second Form of 6:6'-Dinitrodiphenic Acid and its Conversion into New Cyclic Systems": J. Kenner and W. V. Stubbings. (3) "The Structural Isomerism of Oximes. Pt. III. A fourth benzildioxime": F. W. Atack and L. Whinyates.

The president announced that the guests of honour who will be entertained at the Anniversary Dinner to be held on March 17 are: Sir James Dewar, Sir Edward Thorpe, and Sir William Tilden, all past-presidents who have attained their jubilee as Fellows of the Society.

CORRESPONDENCE.

ORIGIN OF THE SOCIETY OF CHEMICAL INDUSTRY.

Sir,—It is difficult to understand the misleading statements made by Mr. Douglas Hermann in his letter relating to the inception of the Society of Chemical Industry which appeared in the *Journal* of January 31; and, as one concerned in the formation of this Society, I feel constrained to place before your readers the following facts relating thereto:—

On the occasion of a visit to Newcastle, Mr. T. W. Stuart (then manager of Messrs. Tennant's works, and now the United Alkali Co.'s general manager) invited me to attend a meeting of what was then known as The Tyne Chemical Society. Realising the great advantages accruing from the intimate association and frequent conferences of those engaged in chemical manufacture, on my return to Widnes I convened a meeting of chemists and managers of this district, which was held in the Y.M.C.A. rooms of this town, on November 21, 1879, to consider the advisability of forming a local chemical society similar to the one referred to. The following gentlemen attended that meeting: Messrs. MacIllwain, Northing, Tallon, Williamson, Taylor, Marsh, Lord, Campbell, Bottomley, Coxon, and Hargreaves. Messrs. MacIllwain, Tallon, Coxon, Campbell, with myself as hon. sec., were appointed an executive committee and held a meeting on December 1, 1879, when it was resolved that a general meeting be held on December 5, at which the following recommendation, among others, should be presented for consideration: "That the name of the society be the South Lancashire Chemical Society."

When sending out the usual notices for this general meeting, I wrote Mr. James Muspratt, inviting him to be present. The meeting was held in due course and was presided over by Mr. James Muspratt (who had not hitherto attended the preliminary meetings). It was resolved that a special committee be formed to draft rules to be placed before the next general meeting, and also to arrange time and place for such meeting. This was held on January 29, 1880, at the Royal Institution, Liverpool, Dr. Mond presiding. The following letter was received from Prof. Roscoe in reply to the secretary's invitation asking him to attend that meeting:—

"The Owens College, Manchester,
Jan. 24, 1880.

"Dear Sir,—In reply to your circular of yesterday's date, I beg to say that I consider your proposal to found a Chemical Society for Lancashire on the basis of the Newcastle Society a very useful one, and it will give me much pleasure to assist those interested in its formation in every way in my power. I regret, however, that my engagements next week prevent me from attending the meeting in Liverpool on Thursday.—Yours truly,
"H. E. Roscoe.

"John Hargreaves, Esq."

At a further meeting, held at Owens College, on April 19, 1880, the late Mr. G. E. Davis (whom I had approached privately), was appointed hon. secretary. During that meeting a few gentlemen, at Mr. Davis's suggestion, withdrew to an adjoining room, where our first subscriptions to the Society were paid. Up to that time all the expenses had been borne by me personally, and Mr. Davis insisted that I be reimbursed from the monies he then held as subscriptions. Concerning the Faraday Club and the alleged jealousy of the Widnes chemists, referred to by Mr. Hermann, I may say that the existence of this club only became known to me at that time through a local chemist when he was invited to join the projected Society.

Asked by Mr. Davis some years after the formaion of the Society whether I knew the reason he ittended the meeting held in the Drill Hall on December 5, 1879, over which Mr. James Muspratt presided, he declared, "I came to smash it up." Fortunately for the Society, "coming to scoff, he emained to pray." I know of no man who, colaborating with the late Mr. Tyrer, would or could ave so efficiently devoted the very large amount of time and energy required in mothering the infant Society and establishing it on its present firm oundation, and without whom the Society could never have become such an influential organisation.

I give the above details—which are only a few of he facts I have available—as there seems to be so nuch misconception still prevalent concerning the rigin of the Society of Chemical Industry.—I am, Sir, etc., JOHN HARGREAVES.

Widnes, March 1, 1921.

PERSONALIA.

The President of the Society, Sir William J. Pope, has been elected "Membre d'Honneur" of he Société de Chimie Française.

Mr. A. Chaston Chapman has been elected president of the Institute of Chemistry, in succession to ir Herbert Jackson.

The Perkin Medal of the Society of Dyers and Colourists has been awarded to Mr. H. A. Lowe for is invention of the process for mercerising cotton nder tension.

Mr. A. J. Greenaway has been appointed editor f the Journal of the Chemical Society, in succession o Dr. J. C. Cain, and Dr. Clarence Smith becomes ssistant editor.

The fifteen candidates who have been selected by ie Council of the Royal Society to be recommended or the Fellowship include Dr. F. W. Aston, Prof. W. L. Bragg, Prof. K. J. P. Orton, and Prof. J. C. Philip.

Dr. M. O. Forster will preside over Section B (Chemistry) of the British Association for the Advancement of Science at the meeting to be held from eptember 7 to 14, in Edinburgh. Sir Edward horpe is president-elect of the Association.

Prof. J. v. Braun, of the Berlin Agricultural Hochschule," has accepted the chair of chemistry t the University of Frankfurt as successor to Prof. reund, and Prof. H. Fühner, of Königsberg, has een called to the chair of pharmacology in the niversity of Leipzig, in succession to Prof. R. oehm, retired.

The testing station for new medicinal preparaons recently established at Berlin has been placed nder the direction of Geheimrat Heffter, of the harmacological Institute, Berlin University, and rof. Holste, in Jena, has been given charge of the eadquarters of the Medicinal Preparations Comission of the Society for Internal Medicine.

With deep regret we record the death of the Rt. Hon. Lord Moulton, on March 9 at the age of 75.

Sir Charles A. Cameron, superintendent medical officer of public health and city analyst to the Dublin Corporation, died on February 27, at the age of 90.

The death is announced of Dr. R. Suchsland, who for over fifty years was chief chemist to Messrs. Vivian and Sons, of Swansea. The deceased was born in Frankfurt in 1839, was engaged by the late Lord Swansea in 1861, and became naturalised in the early seventies.

The death of Dr. Ignaz Stroof, one of the pioneers of the German heavy chemical industry, took place in November last, in his eighty-third year. His most important work was the introduction of the electrolytic method of manufacturing caustic alkali by the diaphragm process.

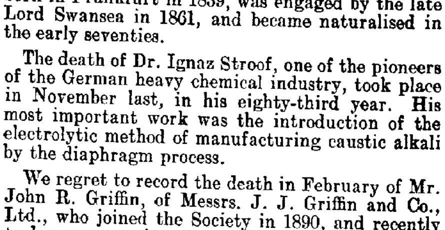
We regret to record the death in February of Mr. John R. Griffin, of Messrs. J. J. Griffin and Co., Ltd., who joined the Society in 1890, and recently took a very active part in the work of the committee appointed by the Council to investigate the standardisation of laboratory glassware (*cf.* J., Aug. 15, 1919; also the death of Mr. S. H. Blichfeldt on March 3, after a very short illness.

NEWS AND NOTES.

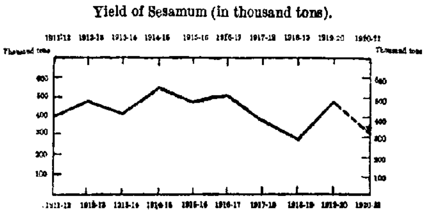
BRITISH INDIA.

The Sesamum Industry.—The *Indian Trade Journal* of January 28 contains the detailed final memorandum on the sesamum crop of 1920-21, together with charts (reproduced below) showing the present estimates of the total area and yield as compared with the final figures of the preceding nine years:—

Area under Sesamum (in million acres).



Yield of Sesamum (in thousand tons).



Exclusive of Burma, which contains nearly 25 per cent. of the area under sesamum in British India, the total area under the crop is reported to be 3,964,000 acres, or 2 per cent. below the corresponding revised estimate last year, and the total yield (Hyderabad and Burma excluded) is estimated at 323,000 tons, which is 20 per cent. below the forecast this time last year. The condition of the crop is reported to be fair on the whole.

character were able to render valuable service to the State. It was probably desirable at the present moment for the Council of the Institute, without taking part in politics, to express its views on the grave importance of maintaining in this country industries on which not only the future development of our chemical industry and many allied industries depends, but the future of a very large number of students of chemistry who are now being trained. The Institute was entrusted by its charter to secure the supply of well-trained chemists, but unless a great chemical industry was maintained their prospects would be very poor. The president maintained that the Institute had throughout its existence fulfilled the purposes for which it was incorporated. It had kept alive the corporate spirit of the profession; it was the officially recognised public body to which the country could turn for advice and guidance on matters relating to the profession; it assisted those who intended to follow the profession of chemistry, and promoted and maintained the highest standard of training and competence for that profession; it registered the trained and competent, and it fostered the strictest integrity on the part of its members in their dealings with one another and with the public. He was confident that it would continue to gain strength and prestige.

SOCIETY OF PUBLIC ANALYSTS.

An ordinary meeting was held at the Chemical Society's Rooms on March 2, Mr. A. Smetham presiding.

A paper on "The Acidity of Ink and the Action of Bottle Glass on Ink" was read by Mr. C. A. Mitchell, who explained why acid was added to ink, gave the amount present in standard inks, and described acid-free inks, the estimation of acidity, and the difficulty caused by the presence of dyestuffs. The uses and limitations of the hydrogen-peroxide method and the estimation of total acidity as a check on the manufacturing process were dealt with and the effects of glass on ink discussed.

In a paper on "The Detection of Adulteration in Butter by means of the Melting-point of the Insoluble Volatile Acids," Mr. G. van B. Gilmour described how the addition of small amounts of coconut and palm-kernel fats to butter appreciably lowers the melting-point of the insoluble volatile acids. Tables of melting-points and distillation-figures for pure fats and mixtures were given, and also graphs showing how the melting-point is affected by adding increasing quantities of coconut and of palm-kernel fat.

Messrs. S. H. Blichfeldt and T. Thornley described a method and apparatus for routine determinations of melting-points of fat and fatty acids, in which a column of melted fat 1 cm. long in a tube of 1 mm. bore, 3 mm. diameter, and 60 mm. length, is rapidly solidified on ice and kept there for two hours; the tube is then placed in a water-bath with the upper level of the column 1 cm. below the surface, and heated at the rate of 1° C. per minute. The temperature at which the column rises is taken as the melting-point. The apparatus consists of a rectangular glass water-bath holding twenty tubes, which is heated, stirred, and illuminated electrically.

THE CHEMICAL SOCIETY.

At the meeting held on March 3, Sir James Dobbie presiding, the following papers were read in abstract:—(1) "The Chemistry of the Glutaconic Acids. Pt. XII. The simultaneous occurrence of 1:2- and of 1:3-addition to glutaconic ester. A study in mobile equilibrium involving the utilisation of the labile ester in the 'nascent' condition": C. K. Ingold and J. F. Thorpe. (2) "A Second Form of 6:6'-Dinitrodiphenic Acid and its Conversion into New Cyclic Systems": J. Kenner and W. V. Stubbings. (3) "The Structural Isomerism of Oximes. Pt. III. A fourth benzildioxime": F. W. Atack and L. Whinyates.

The president announced that the guests of honour who will be entertained at the Anniversary Dinner to be held on March 17 are: Sir James Dewar, Sir Edward Thorpe, and Sir William Tilden, all past-presidents who have attained their jubilee as Fellows of the Society.

CORRESPONDENCE.

ORIGIN OF THE SOCIETY OF CHEMICAL INDUSTRY.

Sir,—It is difficult to understand the misleading statements made by Mr. Douglas Hermann in his letter relating to the inception of the Society of Chemical Industry which appeared in the *Journal* of January 31; and, as one concerned in the formation of this Society, I feel constrained to place before your readers the following facts relating thereto:—

On the occasion of a visit to Newcastle, Mr. T. W. Stuart (then manager of Messrs. Tennant's works, and now the United Alkali Co.'s general manager) invited me to attend a meeting of what was then known as The Tyne Chemical Society. Realising the great advantages accruing from the intimate association and frequent conferences of those engaged in chemical manufacture, on my return to Widnes I convened a meeting of chemists and managers of this district, which was held in the Y.M.C.A. rooms of this town, on November 21, 1879, to consider the advisability of forming a local chemical society similar to the one referred to. The following gentlemen attended that meeting: Messrs. MacIllwain, Northing, Tallon, Williamson, Taylor, Marsh, Lord, Campbell, Bottomley, Coxon, and Hargreaves. Messrs. MacIllwain, Tallon, Coxon, Campbell, with myself as hon. sec., were appointed an executive committee and held a meeting on December 1, 1879, when it was resolved that a general meeting be held on December 5, at which the following recommendation, among others, should be presented for consideration: "That the name of the society be the South Lancashire Chemical Society."

When sending out the usual notices for this general meeting, I wrote Mr. James Muspratt, inviting him to be present. The meeting was held in due course and was presided over by Mr. James Muspratt (who had not hitherto attended the preliminary meetings). It was resolved that a special committee be formed to draft rules to be placed before the next general meeting, and also to arrange time and place for such meeting. This was held on January 29, 1880, at the Royal Institution, Liverpool, Dr. Mond presiding. The following letter was received from Prof. Roscoe in reply to the secretary's invitation asking him to attend that meeting:—

"The Owens College, Manchester,
Jan. 24, 1880.

"Dear Sir,—In reply to your circular of yesterday's date, I beg to say that I consider your proposal to found a Chemical Society for Lancashire on the basis of the Newcastle Society a very useful one, and it will give me much pleasure to assist those interested in its formation in every way in my power. I regret, however, that my engagements next week prevent me from attending the meeting in Liverpool on Thursday.—Yours truly,
"H. E. Roscoe.

"John Hargreaves, Esq."

At a further meeting, held at Owens College, on April 19, 1880, the late Mr. G. E. Davis (whom I had approached privately), was appointed hon. secretary. During that meeting a few gentlemen, at Mr. Davis's suggestion, withdrew to an adjoining room, where our first subscriptions to the Society were paid. Up to that time all the expenses had been borne by me personally, and Mr. Davis insisted that I be reimbursed from the monies he then held as subscriptions. Concerning the Faraday Club and the alleged jealousy of the Widnes chemists, referred to by Mr. Hermann, I may say that the existence of this club only became known to me at that time through a local chemist when he was invited to join the projected Society.

Asked by Mr. Davis some years after the formation of the Society whether I knew the reason he attended the meeting held in the Drill Hall on December 5, 1879, over which Mr. James Muspratt presided, he declared, "I came to smash it up." Fortunately for the Society, "coming to scoff, he remained to pray." I know of no man who, collaborating with the late Mr. Tyrer, would or could have so efficiently devoted the very large amount of time and energy required in mothering the infant Society and establishing it on its present firm foundation, and without whom the Society could never have become such an influential organisation.

I give the above details—which are only a few of the facts I have available—as there seems to be so much misconception still prevalent concerning the origin of the Society of Chemical Industry.—I am, Sir, etc., John Hargreaves.

Widnes, March 1, 1921.

PERSONALIA.

The President of the Society, Sir William J. Pope, has been elected "Membre d'Honneur" of the Société de Chimie Française.

Mr. A. Chaston Chapman has been elected president of the Institute of Chemistry, in succession to Sir Herbert Jackson.

The Perkin Medal of the Society of Dyers and Colourists has been awarded to Mr. H. A. Lowe for his invention of the process for mercerising cotton under tension.

Mr. A. J. Greenaway has been appointed editor of the Journal of the Chemical Society, in succession to Dr. J. C. Cain, and Dr. Clarence Smith becomes assistant editor.

The fifteen candidates who have been selected by the Council of the Royal Society to be recommended for the Fellowship include Dr. F. W. Aston, Prof. W. L. Bragg, Prof. K. J. P. Orton, and Prof. J. C. Philip.

Dr. M. O. Forster will preside over Section B (Chemistry) of the British Association for the Advancement of Science at the meeting to be held from September 7 to 14, in Edinburgh. Sir Edward Thorpe is president-elect of the Association.

Prof. J. v. Braun, of the Berlin Agricultural "Hochschule," has accepted the chair of chemistry at the University of Frankfurt as successor to Prof. Freund, and Prof. H. Führer, of Königsberg, has been called to the chair of pharmacology in the University of Leipzig, in succession to Prof. R. Boehm, retired.

The testing station for new medicinal preparations recently established at Berlin has been placed under the direction of Geheimrat Heffter, of the Pharmacological Institute, Berlin University, and Prof. Holste, in Jena, has been given charge of the headquarters of the Medicinal Preparations Commission of the Society for Internal Medicine.

With deep regret we record the death of the Rt. Hon. Lord Moulton, on March 9 at the age of 75.

Sir Charles A. Cameron, superintendent medical officer of public health and city analyst to the Dublin Corporation, died on February 27, at the age of 90.

The death is announced of Dr. R. Suchsland, who for over fifty years was chief chemist to Messrs. Vivian and Sons, of Swansea. The deceased was born in Frankfurt in 1839, was engaged by the late Lord Swansea in 1861, and became naturalised in the early seventies.

The death of Dr. Ignaz Stroof, one of the pioneers of the German heavy chemical industry, took place in November last, in his eighty-third year. His most important work was the introduction of the electrolytic method of manufacturing caustic alkali by the diaphragm process.

We regret to record the death in February of Mr. John R. Griffin, of Messrs. J. J. Griffin and Co., Ltd., who joined the Society in 1890, and recently took a very active part in the work of the committee appointed by the Council to investigate the standardisation of laboratory glassware (*cf.* J., Aug. 15, 1919; also the death of Mr. S. H. Blichfeldt on March 3, after a very short illness.

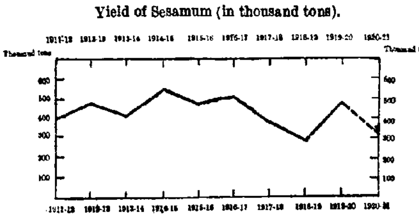
NEWS AND NOTES.

BRITISH INDIA.

The Sesamum Industry.—The *Indian Trade Journal* of January 28 contains the detailed final memorandum on the sesamum crop of 1920–21, together with charts (reproduced below) showing the present estimates of the total area and yield as compared with the final figures of the preceding nine years:—

Area under Sesamum (in million acres).

Yield of Sesamum (in thousand tons).



Exclusive of Burma, which contains nearly 25 per cent. of the area under sesamum in British India, the total area under the crop is reported to be 3,964,000 acres, or 2 per cent. below the corresponding revised estimate last year, and the total yield (Hyderabad and Burma excluded) is estimated at 323,000 tons, which is 20 per cent. below the forecast this time last year. The condition of the crop is reported to be fair on the whole.

Indigo Cultivation in Assam.—Recent experiments appear to indicate that indigo grown in Assam will prove a formidable competitor of synthetic indigo. Plants have been grown in Assam containing 0·7 per cent. of indigotin in the leaf, yielding 60—80 lb. of cake indigo per acre. A company called "Assam Indigo, Ltd.," has been formed for the purpose of producing indigo by modern methods.—(*U.S. Com. Rep., Feb.* 4, 1921.)

AUSTRALIA.

Oil Exploration.—Stimulated by the Government's offer of a prize of £50,000, the search for oil in paying quantities is being pursued vigorously. The Northern Territory, Papua, and South Australia are being explored, but so far only the Roma bore in Queensland and the bores in Papua are considered hopeful; in neither of these localities has oil yet been produced on a commercial scale.

New South Wales.

Cultivation of Groundnuts.—Many farmers are now cultivating this crop. The heavy loams of the northern coast of the State are the most suitable, but some good crops have been obtained on the Murrumbidgee irrigation areas. A firm in Sydney is erecting an oil-extraction plant which, it is hoped, will be in full working order before the next crop is harvested.

Victoria.

Chemistry at Melbourne University.—In commemoration of its late chairman, Mr. James Cumming, a leader of Victorian chemical industry, the directors of Cumming, Smith and Co., Pty., Ltd., have offered the sum of £5000 towards the erection and equipment of a research laboratory and lecture-theatre in the University of Melbourne. The offer is being considered by the council of the University.

Western Australia.

Forest Products.—The following notes have been abstracted from the recently issued Report of the Conservator of Forests for the year 1919–20. The gross value of exported timber during the year, including sandalwood, amounted to £743,373, an increase of £263,307 over the previous year.

Kiln Drying.—The future of kiln drying of jarrah being assured, both by the results obtained by the Department and by local firms in their commercial driers, the timber kiln erected at Crawley has been operated during the year with a view to overcoming some of the difficulties encountered. It is hoped that before long all the information required to enable such kilns to be operated easily and successfully will be available.

Tan Barks.—The value of mallet bark exported amounted to £22,121, or £3246 more than in 1918–19. Mangrove bark has come into prominence, analysis having shown that the black mangrove (*Bruguiera gymnorrhiza*) contains 46 per cent. and the red mangrove (*Ceriops candolleana*) 44 per cent. of tannin. Marri kino tannage continues to be used for sole and harness leather. The tanneries of Western Australia are still dependent on Natal wattle bark, and every attempt should be made to find local substitutes to reduce this importation. The trees and shrubs in the State contain sufficient tanning-bearing materials not only for local tanneries, but also for export.

Sandalwood.—This trade is a purely Chinese one, and the average quantity of sandalwood absorbed by China during the past 70 years is 4500 tons per annum. During the year under review, however, the cut amounted to 17,269 tons. This very large increase is difficult to explain, but the main cause is probably the very high rate of exchange which followed the rise in the price of silver, and consequently of the Chinese dollar. Owing to the alarming rate of cutting, an attempt was made to regulate the industry by raising the royalty on the wood from 5s. to £2 per ton. Although this gives a considerably increased revenue, it does not affect the main object of regulating the supply of wood to that quantity which China can absorb, and so assuring a continuous trade at a maximum price. During the year 5572 lb. of sandalwood oil was extracted locally, an increase of 1852 lb. over the previous year's output.

Kingia Grass Tree Fibre Industry.—This new industry is developing gradually and the excellence of the fibre for broom making and other purposes has been proved. During the year the "Dibenya" fibre works shipped 27 tons to the Eastern States, and a second factory has just started operations. So far only the fibre of this tree has been used; the outside is stripped in the bush and the inside core also goes to waste. This is a matter demanding immediate attention, for at the present time only about one-fifth of the crop is being utilised.

CANADA.

Glass Production in Vancouver.—A large plant for the manufacture of table ware is under construction at Westmoreland, near Huntingdon, in West Vancouver, for the West Virginia Glass Manufacturing Co.; it will include a glass furnace, said to be the largest in the world, employ 400—500 work-people, and be ready for a trial run in April.—(*Oil, Paint and Drug Rep., Jan.* 31, 1921.)

FRANCE.

Industrial Notes.—*Coal.*—The French coal industry was decontrolled on March 1, and the supertax of 28 per cent. abolished; the pithead tax is retained in order to keep down prices. The supertax was intended to equalise the prices of home and foreign coal, but as the differences in price have of late been reduced by nearly 50 per cent. its continuance is unnecessary. The total output of coal in France, including Lorraine, was 25,276,304 tons in 1920, compared with 22,476,766 t. in 1919. The total production of coke made from Saar coal is about 87,000 t. monthly; the average selling price of the coal and coke is about 97 francs per ton, and the profit 13 fr. per ton, half of which has to be applied to extension work. In view of the possible eventual restoration of the Saar mines to Germany, it is proposed to exploit them to the fullest extent.

Metallurgy.—Opposition to the great metallurgical syndicates continues to grow. The Comptoir de Longwy, as already announced, has been liquidated; it is rumoured that the Comptoir des Fontes Hematites will soon share the same fate; and the Comptoir Sidérurgique, which sells and distributes semi-manufactured and manufactured products, is also becoming unpopular. The opposition emanates from the federation of producers that has been formed since the war, and which by reason of its control of blast furnaces, steel works, rolling mills and a powerful selling organisation, no longer requires intermediaries such as the syndicates mentioned above. It is, however, doubtful if these can be permanently dispensed with, as the country is already producing twice as much pig iron as it consumes, and central organisations will be required to dispose of the surplus production to foreign buyers.

Chemical Industry.—German competition in fine chemicals is steadily growing. French producers who had found a market in Brazil, Chile, and Argentina are being gradually ousted by Darmstadt and Hamburg firms which undersell them by about 10 per cent. on quoted prices. Competition is not so active in heavy chemicals on account of the long periods required for delivery and of the high transport rates. The prohibition of the export of new and scrap celluloid, oil of turpentine and fertilisers has been revoked in order to facilitate the liquidation of existing stocks.

UNITED STATES.

Treatment of Alkaline Soils with Sulphuric Acid.—Considerable interest has been aroused by favourable results obtained in the south-west by the direct application of sulphuric acid to adobe soils. Plots upon which nothing had been raised hitherto proved to be fertile after this treatment. This is said to be due both to the correction of super-alkalinity and to improvement in the physical character of soils treated.

Extraction of Potassium Chloride and Borax from Natural Brines.—At Keeler, California, a new process is being worked for recovering potassium chloride and borax in marketable form from natural brines. After securing the greatest possible concentration by solar evaporation the liquor is treated with carbon dioxide to free it from the carbonates of soda. It is then concentrated further in double-effect evaporators and submitted to fractional crystallisation.

Propyl Alcohol from Wood Waste.—A process for making propyl alcohol from the waste gases of the Burton petroleum-cracking still is being worked commercially. These gases contain large quantities of propylene, and after hydrogen sulphide has been removed they are passed through sulphuric acid, which combines with the propylene, and propyl alcohol is then obtained by distillation. Isopropyl alcohol can be oxidised directly to acetone, or a series of esters of commercial importance can be made from it. The new alcohol will be called "petrohol," and the present capacity of the plant is 250 galls. per day. It is anticipated that this alcohol will be produced in competition with methanol, the new commercial term for wood alcohol, as a solvent for gums and resins.

The Chemical Warfare Service.—The American Chemical Society, through its Committee on National Policies, has communicated the following resolution to members of the Senate and the House of Representatives:—

"While in complete accord with the spirit prompting the restrictions of appropriations by the present Congress, nevertheless the American Chemical Society's Committee on National Policies would urge upon the Congress more favourable provision for the Chemical Warfare Service than is contemplated by the amount set by the House of Representatives—$1,500,000. The carefully prepared estimates of the officers of that Service, slightly less than $4,500,000, represent less than 1¼ per cent. of the total appropriation for the army carried in the House bill. This amount is to care for the valuable property of the Government at Edgewood Arsenal, to enable the continuation of research on new lines of defence and offence, and to provide for the training of special troops and for the instruction of the entire army in all features of gas warfare. In view of the tremendous increase in the use of gases during the last year of the war, and of the fact that approximately 30 per cent. of the casualties of our army in the war was due to gas wounds, we feel that the proposed reduction to one-third of the appropriation asked would so seriously cripple the development of the Chemical Warfare Service as to constitute a matter of grave national concern. We therefore urge that the Congress appropriate the original amount asked for the Service in the estimates submitted."

Mica in 1918.—A report of the United States Geological Survey issued in 1920 gives the production of mica in that country in 1918 as 3114 short tons, which comprised 822 t. of sheet and 2292 t. of scrap mica. As in previous years (*cf.* J., 1918, 437 R), the greatest production was in North Carolina, but increasing quantities of excellent mineral are now being obtained from the Thomaston field in Georgia. Production is apparently at its maximum, the stimulus of high prices and a ready market having had little effect. Of the mica imported in 1918, 54 per cent. came from India, 26 per cent. from Canada, and 15 per cent. from Brazil. The value of the imports, $1,541,129, was approximately double that of the exports.

No figures are available for the world's production in 1918, but India and Canada produced 3062 and 374 t. respectively. To-day the largest consumers are the United States and Great Britain, followed by France and Italy, Germany having lost her leading position in the European electrical industry to England. The future development of mica deposits depends to some extent on the success of various substitutes, *e.g.*, compressed-paper products, bakelite, etc. So far there appears to be no satisfactory substitute for sheet mica used in electrical insulation, for which purpose no less than 86 per cent. of the sheet mica and splittings produced is utilised. About 98 per cent. of the world's output of sheet mica is supplied by India and the United States (muscovite) and Canada (phlogopite). The demand keeps pace with increasing production, and important developments may be expected in British East Africa, Nyassaland, and Rhodesia.

Nitrobenzene-Poisoning.—A peculiar case of poisoning due to nitrobenzene has been reported. A workman who treated his shoes with a preparation containing this substance and wore them immediately was taken ill within three hours. The desirability of not wearing shoes so treated within three or four days of treatment and applying the substance in a well-ventilated place are emphasised.

SOUTH AFRICA.

Industrial Progress.—The report of the General Manager of Railways and Harbours for the year 1919–20 records considerable industrial expansion. Although attention has been devoted mainly to expanding and modernising existing industries, new industries are still springing up, and they have been to a great extent shielded from foreign competition by the continuance of war-prices in exporting countries. Compared with the year 1915–16, there are 2044 additional factories, 41,910 more employees, and the value of the production has increased by £30,000,000.

The iron and steel industry should in time become one of the most important in the Union. Although small it is making satisfactory progress. In 1919 the production of iron and steel goods from local furnaces was valued at £406,000, and 1967 tons of pig iron, valued at £12,500, was produced from local ore. The trade in wattle bark and wattle-bark extract continues to grow; 96,124 tons of bark was shipped from Durban during the year ended March, 1920, and eleven mills for making extract have been established or are in course of erection. The value of the exports in this industry has increased from £195,000 in 1909 to £603,000 in 1919. The tanning and leather goods industry has been active throughout the Union, notably at Durban, Port Elizabeth, King William's Town, Wellington, Pretoria, and Middleburg There is a ready market for local products, and the factories are unable to keep pace with the demand. Leather and leather goods to the value of £62,000 were exported in 1919, or £56,000 more than in 1909.

JAPAN.

The Cement Industry.—The Nagoya Cement Co. has recently completed its plant at Tokyo, and the output, which it is anticipated will reach 200,000 barrels per annum, will be taken largely by hydro-electric companies. The company owns mining rights for limestone in the Shiga and Miye Prefectures.—(*U.S. Com. Rep., Jan.* 4, 1920.)

GENERAL.

Mercerised Cotton.—As announced on page 87 R, the Perkin Medal of the Society of Dyers and Colourists has been awarded to H. A. Lowe for his invention of mercerised cotton under tension.

The process of treating cotton with a strong solution of caustic soda produces a change in the fibre known as "mercerisation," a word derived from the name of John Mercer, who first drew attention to the phenomenon in 1844, but today it is more particularly associated with cotton upon which a lustre has been produced by treatment with caustic soda while under tension. The production of a permanent lustre was the discovery of Horace A. Lowe, whose patents were taken out in 1889 and 1890. Lowe, then a young chemist in a Lancashire bleach-works, experienced so much difficulty in getting the process taken up that he allowed his patents to lapse. The process was first carried out on a commercial scale in 1895 by Thomas and Prevost of Crefeld, who took out a patent, apparently in ignorance of Lowe's previous discovery. The mercerised yarns produced by this firm met with such success that the process was widely taken up. In the litigation which naturally followed, the priority of Lowe's invention was clearly established, and Thomas and Prevost's patent was annulled. Lowe subsequently carried out his process at a works opened for the purpose near Manchester, and after a short time this was taken over by the Fine Cotton Spinners' Association, who began the production of mercerised yarns on a very large scale. Today mercerisation is one of the most important processes in use in the cotton dyeing and finishing trade.

Former recipients of the Perkin Medal have been von Baeyer for the synthesis of Indigo, Graebe and Liebermann for the synthesis of Alizarin, de Chardonnet for the invention of the first artificial silk, and Prof. Arthur Green for the discovery of Primuline.

"**Bismuth** (1913—1919)" (pp. 14, price 6d.) has been recently published by the Imperial Mineral Resources Bureau as an advance "part" of its annual volume on the Mineral Resources of the British Empire and Foreign Countries. The Bureau does not appear to be able to add appreciably to our knowledge concerning the production and marketing of bismuth ores, metal, or compounds. The table headed "World's Production of Bismuth" shows figures which are of little value, as it only gives the production of ore, concentrates, residues, etc., without stating the bismuth content and without giving the values. The largest producing country is Bolivia, which in 1918 was stated to have produced 245 tons of bismuth ingots, presumably sent to England to be refined. As a rule, the Bolivian native bismuth and high-grade concentrates are shipped to Europe and the United States for treatment, only the low-grade concentrates carrying less than 10 per cent. bismuth being smelted locally. Australia is a producer on a considerable scale and, although no figures are given for the production in the United States, the supply obtained during the process of smelting and refining lead and copper ores in that country must be an important source of the metal. Smaller quantities of bismuth ore have been produced in Rhodesia, India, Burma, China, and Norway. Figures for Germany are not available, but this country is normally an important producer.

During the war there was an increased demand for bismuth both for the manufacture of certain low-temperature fuses and for medicinal purposes. Both the production of bismuth and the market price of the metal have been strictly controlled for many years. Messrs. Johnson, Matthey and Co., Ltd., are the chief buyers, and they report official prices per lb. of the metal as follows:—January, 1912, to August, 1914, 7s. 6d.; August, 1914, to March, 1916, 10s.; March, 1916, to January, 1918, 11s.; January, 1918, to January, 1920, 12s. 6d. It is stated that bismuth ore to be marketable should contain at least 10 per cent. metallic bismuth, but it is well known that tinny and other residues containing 5 per cent. have been readily saleable during the last few years.

Palm Oil as Fuel for Internal Combustion Engines.—Major Trentels, of the Belgian colonial army, has recently described some interesting trials of palm oil in a two-cycle semi-Diesel engine of 8—10 h.p. at 500 rev. per min. The only special feature related to the means for keeping the fuel liquid, and this was accomplished by using the cylinder cooling-water in conjunction with the hot exhaust-gases. The engine was started on petrol, and arrangements were made for the termination of the run to be carried out on the same fuel so as to remove palm oil from the feed pipes. The palm-oil consumption was 0·68 to 1·21 lb. per h.p.-hr. for powers between 3·5 to 120 h.p. The calorific value of the fuel was 16,610 B.T.U., and its price was 250 fr. per metric ton (crude petroleum being about 2000 fr. per metric ton). Other vegetable oils have been suggested at various times for use as motor fuel, such as castor oil and groundnut oil, but the advisability of using for fuel any oil which can be utilised for edible purposes is very doubtful.—(*Times Eng. Suppl., Feb.*, 1921.)

The Chemical Treatment of Seeds.—Various methods of treating seeds have recently been brought forward in France to improve vegetative growth and to obtain increased yields by steeping them in a solution containing a fertiliser, *e.g.*, potassium nitrate, ammonium sulphate, ammonium phosphate, etc., either singly or in admixture. Investigations by Dr. Worley, of Munich, in 1886 led him to conclude that the steeping of seeds in such a solution has no more effect than immersion in pure water; that germination in such cases is stimulated solely by imbibition; and that solutions of many fertilisers are harmful unless used in very low concentration. Later, M. André, of the Institut National Agronomique, found that most seeds are killed even by a very weak acid solution, and that although many saline solutions facilitate germination when used in concentrations not exceeding 0·2—0·4 per cent., they might be harmful in higher concentrations. Further trials were carried out in France by M. Bachelier, using barley seeds and potassium nitrate, but the results, like those obtained by various Agricultural Services, were inconclusive. The excellent results said to have been obtained by M. Pion-Gaud, who used a 2 per cent. solution of ammonium nitrate, were due less to steeping than to special methods of cultivation. Certain liquids of secret composition, reported to have given favourable results, are now being officially investigated. The general conclusion seems to be that, although germination can be stimulated by steeping the seed in a nutrient liquid, pure water is sufficient and preferable.—(*Official.*)

Guano Deposits on Latham Island, near Zanzibar.—The central plateau of Latham Island, a small island situated to the south-east of Zanzibar, is covered with a deposit of guano one foot deep, a sample of which was analysed at the Imperial Institute and found to contain: Citric-soluble P_2O_5, 19·1% (total P_2O_5, 29·52%); K_2O, 0·33%; and CaO, 35·36%. It resembles the guano obtained from Saldanha Bay, South Africa, and contains more phosphate and less nitrogen than typical Peruvian guano. Freight rates are at present too high to permit of exporting the guano to the United Kingdom, but a market might possibly be found for it in East Africa or Zanzibar.—(*Bull. Imp. Inst.*, **18**, 2, 1920.)

The Effect of the Inhalation of Gases.—Under this title, Dr. G. A. Welsh summarises his experiences at H.M. Factory, Gretna, in the January issue of the *Journal of Industrial Hygiene.* Volume for volume, says Dr. Welsh, the compounds of sulphur and oxygen are less dangerous than nitrogen oxides or nitrosyl chloride, and sulphuric acid fumes are less harmful than those of nitric acid. From the nature of the substance causing gassing and from observation of the symptoms, it is possible to give a fairly accurate prognosis in all cases except those of gassing by nitrogen peroxide and nitric acid mist. In the majority of severe cases the urgent symptoms subside in 24 hours, although a few last for 48 hours; and it is then a question of dealing with pharyngitis, laryngitis, bronchial irritation or bronchitis. With pharyngitis and bronchitis it is advisable to give the patients a change of air and surroundings for a week before certifying them as fit to return to work.

The wearing of respirators by operatives was discontinued at Gretna after many trials; the operatives dislike them, and as gassing is usually the result of an accident, it is impossible to be sure that the operative will be wearing a respirator at the time of the accident. The only exception is the wearing of moist cotton-wool well over the mouth and nose by nitrocotton dippers; this cannot be called efficient, and only a self-contained apparatus, such as the "Mecco" has been found to trap nitrogen peroxide fumes effectively. The Mecco provides an atmosphere of oxygen from a cylinder and removes carbon dioxide with caustic soda. Of the 361 cases of gassing which occurred at Gretna, only one—a man who inhaled vapours of fuming nitric acid while working in a closed space—ended fatally.

Systemic poisoning, due to inhaling small quantities of toxic fumes from time to time, can only be cured by removal from work and change of air, when a very simple treatment—light fluid diet and alkaline saline mixture—restores to health. There is no evidence that sound teeth are affected by inhaling harmful gases, but if a tooth is already diseased decay is accelerated. Operatives are warned in every case to pay especial attention to the cleansing of the teeth. The article also describes symptoms and first-aid treatment.

Chromium Deposits in Serbia and Bosnia.—The chromium deposit at Raotina, near Skoplje, along the Vardar river, has been worked sporadically in the past. During the war it was exploited by the Germans, who obtained a daily output of about 150 tons. They also worked a second deposit, about 2 kilom. distant from Raotina. Chrome ore was first worked at Dubostica, in Bosnia, in 1884, and during the war the output was about 2000 tons a month. The deposit, which is of considerable extent and width, is owned by the Jugo-Slav Government. Operations are at present suspended, but will be resumed. About 520 t. of high-grade ore was awaiting transportation in June last.—(*U.S. Com. Rep., Dec.* 20, 29, 1920.)

Bauxite Deposits in Istria and Dalmatia.—Little attention was paid to these deposits until during the war, when Germany was obliged to replace supplies formerly derived from France. Exploitation began in 1916, and by the end of 1918, 95,000 metric tons had been exported from Dalmatia and 70,000 t. from Istria. The deposits occur in two zones parallel to the Dinaric Alps, one zone—the most important—being on the mainland and the other on the islands. The ore contains 50—52 per cent. Al_2O_3, 20—24 per cent. Fe_2O_3, and small amounts of silica. Large reserves of ore are said to exist, and as ample water power could be obtained from the river Cherca, the district is suitable for the establishment of an aluminium factory.—(*G. Chim. Ind. ed App., Nov.*, 1920.)

Iron Ore in Switzerland.—The iron mines in the vicinity of Gonzen (Toggenburg) produce 80—100 tons of ore daily, which is transported by telpher. As Switzerland has no blast furnaces, the ore is sent to Germany to be smelted. At the present time production has been greatly reduced on account of the crisis in the iron industry.

The Lignite Mines of Semsales (Switzerland).—In 1920 these mines, which are situate near Fribourg, produced 8000 tons of lignite, of calorific power 5500, which were sold at an average price of 22 francs per car-load. Owing to the reduced price of coal, half of the labour employed has been dismissed, and the other half was offered a reduction in wages of 33 per cent., *i.e.*, from 1·20 fr. to 0·80 fr. per hour. The offer was accepted, as the workers knew that if they refused the whole undertaking would be closed down. The men working above ground now work for 10 hours daily.

Chemical Industry in Czecho-Slovakia.—Since the foundation of the Czecho-Slovak Republic its chemical industries have appreciably recovered from the depression which prevailed during the war; they are well organised individually and also form part of a larger association, the Federation of Czecho-Slovak Industries at Prague. The chemical factories were mainly erected in Bohemia and Moravia, doubtless owing to the excellent transport facilities afforded by the Elbe and the Moldau. Important fertiliser plants are located at Kolin, Slany, Prerau, and Brünn, and those at Slany and Prerau also manufacture glue. Pharmaceutical products are made at Chrast, near Chrudim, and in Prague acids and explosives by the Nobel Dynamite Co. at Bratislava, and paints, varnishes, and shellac at Usti (Aussig). Mineral colours, especially ultramarine and Paris blue, chrome, and zinc colours, are made in many Bohemian towns, and coal-tar dyes are produced by the Aussig Chemical Co. at Usti, and by Kinziberger and Co. at Prague. The dye industry is not firmly established, German competition having proved too formidable in spite of a special high tariff. Ink is made by many firms, and at Ceske Budejovice (Budweis) is the famous plant of L. C. Hardtmuth, making pencils and colours. The manufacture of shoe-blacking is rapidly developing chiefly in North Bohemia. Factories producing greases, oils, essential oils, etc., are found chiefly near the large towns; before the war the production of vegetable oils, *e.g.*, linseed oil, was an important industry in Bohemia, but recently it has had to face competition from the cheaper fish and mineral oils. The soap industry has also suffered from foreign competition, and, since the war, from the liquidation of Government supplies of fats and oils; the largest factory is that of G. Schicht, near Usti, which employs more than 4000 workers. Starch and starch-products are made almost entirely in Moravia and the adjoining parts of Bohemia (*cf.* J., 1920, 17, 275, 306, 400, 438 R).—(*U.S. Com. Rep., Jan.* 21, 1921.)

Discovery of Lead-Silver Ore in Italy.—A rich lode of argentiferous galena has been found in the Alpine part of Valtellina (the upper Adda valley, N. Italy); it is extensive and runs vertically for about 50 ft. into the mountain. About 15 square metres have been opened up, and the ore assays over 65 per cent. of lead, 8 per cent. of silver, with traces of gold and copper.

The Sugar Situation in Italy.—The Italian production of beet sugar in 1920 is estimated at 120,000 metric tons, compared with 192,000 t. in the previous year, the reduction being due, it is believed, to the fixing of the price of beets, which made it more profitable to grow other crops. Sugar is rationed at the rate of 1·1 lb. per head per month, but the home production is insufficient, and im-

portation is necessary. During 1919, 73,000 t. was imported, of which the United States supplied 60,000 t., but during the first eight months of 1920 the total importation was reduced to 6500 t.—(*U.S. Com. Rep., Feb.* 5, 1921.)

Italian Chemical Periodical Literature.—With reference to the statement which appeared on p. 2 R (1921) of this Journal, we are asked to state that the *Giornale di Chimica Industriale ed Applicata* is published jointly by the Associazione Italiana di Chimica Generale ed Applicata of Rome and the Società di Chimica Industriale of Milan.

LEGAL INTELLIGENCE.

Sale of Chemicals in a "Job Lot." *W. Barnes and Co.* v. *C. Wallington and Co.*

In the King's Bench Division on February 17, Messrs. W. Barnes and Co., London, sued Messrs. C. Wallington and Co., of London, to recover damages for alleged breach of contract.

On behalf of plaintiffs it was stated that, after inspection, they had purchased from the defendants some sulphate of soda and soda ash lying in a warehouse. According to the contract notes there were approximately 4½ tons of soda ash at £4 per ton and about 40 tons of sulphate of soda in bags at 30s. per ton, but the defendants only delivered 3 tons 12 cwt. of soda ash and 15 tons 3 cwt. of sulphate of soda. Damages were also claimed because some of the material had to be re-bagged. Without hearing evidence for the defence, Mr. Justice Rowlatt gave judgment for the defendants, with costs. It was abundantly clear that the goods sold and bought "as inspected by purchasers" were a heap—a job lot at a low price, and, in the position they occupied, uncountable; the words "about" and "approximately" meant that the amount was only estimated for the purpose of fixing the price. The plaintiffs' claim in respect of re-bagging also failed.

Validity of Pre-War Contracts. *E. W. J. Coppee and Others* v. *Blagden, Waugh and Co.*

This action was heard before Mr. Justice Rowlatt in the King's Bench Division on February 17. On behalf of plaintiffs it was stated that they carried on business in Belgium, and that early in 1912 they made nine contracts with the defendants for the sale to them of very large quantities of benzol and naphtha, deliveries to last from the beginning of 1914 to the end of 1918. Plaintiffs now asked for a declaration that the contracts were void on the grounds that (1) under the Proclamation of September, 1915, trading with the plaintiffs was forbidden as they were in territory occupied by the enemy; (2) long delay had occurred; and (3) under the Courts Emergency Powers Act, the Court could annul contracts if it was of opinion that the contracts could not be carried out without serious hardship to the contracting parties. Counsel for the defendant company agreed that the contracts still subsisted by virtue of the clause providing that contracts should be suspended in case of war. He also said that the Act referred to did not apply to Belgians, but only to British subjects.

His Lordship held that there had been complete frustration of the contracts owing to the German occupation of Belgium. The suspensory clause did not provide for such a casualty as that which had overwhelmed the plaintiffs and entirely changed the conditions of the contract. Judgment was given for the plaintiffs for the declaration claimed, with costs.

PARLIAMENTARY NEWS.

HOUSE OF COMMONS.

Imports from Germany.

In a written answer to Capt. Terrell, Sir P. Lloyd Greame gave the values of the imports from Germany during the third and fourth quarters of 1920 as £8,743,000 and £10,494,000, respectively. The more important increases were as follows:—

	Third Quarter. 1920. Tons.	Fourth Quarter Tons.
Earthenware	420·6	668·4
Glassware, illuminating	773·4	532·5
Glass bottles	4380·8	5665·4
Lead, pig	1762	3884
Zinc, crude	1644	7671
Potassium nitrate	12	806·4
Silver nitrate	6·2	13·2
Coal-tar dyes	1186·6	2968·4

The values of the coal-tar dyes imported during the two quarters were £1,010,546 and £3,041,798, respectively.—(Feb. 21.)

British America Nickel Corporation.

Sir P. Lloyd Greame, in an answer to Mr. Armitage referring to the statements made in the Seventh Report from the Select Committee on National Expenditure, said that the British America Nickel Corporation, in which the Government had invested $3,000,000 (*cf.* J., 1918, 14 R), had put forward a scheme to raise further working capital and to modify the rights attaching to the various capital issues of the Corporation. No further liability was imposed on the Government by the scheme, which offered the best prospects of a satisfactory realisation of the investment.—(Feb. 21.)

The Dyestuffs (Import Regulation) Act.

In reply to Major Barnes and Mr. Waterson, Sir P. Lloyd Greame said that no decision had been made to restrict the importation of goods under the Dyestuffs Act to those for which the applicant had a definite order, but it would facilitate the granting of licences if it were clear that the dyestuffs were ordered for persons who required them. A complete list of commodities covered by the Act would be available shortly, and information as to the quantities of dyestuffs and other products licensed under the Act would be published periodically; no useful purpose would be served by publishing a list of the firms that had received licences. The refusal to grant an import licence for 2 cwt. of salicylic acid (B.P.) for pharmaceutical purposes would be reconsidered if the applicants could satisfy the Dyestuffs Advisory Licensing Committee that the consignment was of B.P. quality, and intended solely for medicinal use, and if they would undertake to prove later that it had been so used.—(Feb. 21.)

Food Values.

Dr. Addison informed Capt. Elliott that the publication of a pamphlet giving information on the dietetic values of foods was being considered, and certain researches relating thereto were being conducted in collaboration with the Medical Research Council.—(Feb. 25.)

Imports of Gas Mantles.

In a written reply to Sir J. Norton-Griffiths, Sir R. Horne stated that 46,938 gross (value £101,973) of incandescent gas mantles was imported during the six months ended January 31, 1921, and that this quantity was small compared with that in pre-war years. He was aware of the difficulties experienced by the British industry through lack of orders.—(Feb. 28.)

Foreign Competition in the Coal Trade.

Answering Lieut.-Col. Sir F. Hall, Mr. Bridgeman said that the United States exported 476,000 tons of coal to Europe in the year ended June, 1913, and 13,383,000 t. in the calendar year 1920; the coal exported from Australia to Europe was 100 t. in 1913 and 113,000 t. in 1920. The British output of coal during the last six weeks of 1920 seemed to show that a further 13 million tons might have been produced during the year without employing additional labour.—(Feb. 28.)

Sugar Industry (Foreign Competition.)

Mr. Chamberlain, in a written reply to Capt. Bowyer, said that all restrictions on the import of sugar were removed on Febuary 26, after full discussion with the refiners. Apprehensions regarding the effect on the sugar industry of competition from countries enjoying cheaper labour and a favourable exchange were premature, but no statement as to future legislation could be made —(March 1.)

The Key Industries Bill.

Sir P. Lloyd Greame, replying for the Prime Minister to Mr. Terrell, announced that the above Bill would be introduced and proceeded with immediately after Easter.—(March 9.)

REPORTS.

General Report on the Industrial and Economic Situation of Norway in December, 1920. *By* C. L. Paus, *Commercial Secretary to H.M. Legation, Christiania. Department of Overseas Trade. Pp. 75. London: H.M. Stationery Office.* 1921. [*Cmd.* 1145. 9*d.*]

The previous report on Norway (*cf.* J., 1920, 364 R), which covered the war-period down to the end of 1919, has now been supplemented by a general report for the year 1920.

Norway, like other nations which knew prosperity during the war, has now become engulfed in the world-wide depression. The brighter prospects which were apparent in the early months of 1920 disappeared quickly, and the slump which followed has gradually extended to nearly every branch of industry and commerce; labour problems, social unrest, financial stringency, and an abnormal exchange, all contribute to the general depression. The balance of trade is very adverse, and much capital is locked up in stocks. German exporters, favoured by the conditions of exchange, can now undersell all competitors, and are in fact offering their goods, including drugs and chemicals, at very low prices for prompt delivery. Several large German firms have opened offices in Christiania.

The market for heavy chemicals was (in December) very uncertain, and owing to the curtailment of production by the pulp and paper mills, demand was practically non-existent. America sent considerable supplies during the year, and at the close Germany was offering cheap goods to an already glutted market. Many of the factories erected at great expense during the war cannot pay dividends on the invested capital, and with few exceptions production has been greatly curtailed. The carbide industry has suffered from the shortage and high price of imported anthracite; two factories have closed down and the rest are working at 30—40 per cent. of their capacity. The ferro-silicon works are in a still worse position, and the demand for aluminium and refined zinc, which was good in the early part of the year, has diminished.

Mining has been hampered by dear labour and fuel, high freights, and difficulty in obtaining payment from Germany. Production of iron ore has ceased, and pyrites mining is very restricted; it does not pay now to extract the copper from cupreous pyrites owing to the low price of the metal. Nickel, chromium, and molybdenite mines remained closed throughout the year. In the paper-making industry, Finnish and German competition is being felt; the boom which prevailed at the beginning of the year has passed, demand is negligible, and the mills have cut down their production to one-third or less. Exceptionally, the margarine industry has escaped the prevailing depression; demand is described as normal, but profits, owing to competition, will be small. Soap-makers, too, have been busy, and as they are independent of imported oils, they can undersell foreign manufacturers. The nitrate factories controlled by the Norwegian Hydro-electric Nitrogen Co. and the Cellulose and Mechanical Pulp Mills are reported to have been fully occupied throughout the year and to have sold their output some months ahead; it is, however, anticipated that prices will fall.

Report of the Departmental Committee on Control of Certain Therapeutic Substances. *Ministry of Health. Pp.* 13. *H.M. Stationery Office.* 1920. [*Cmd.* 1156. 2*d.*]

This Committee was appointed by the Minister of Health in April, 1920, "to consider and advise upon the legislative and administrative measures to be taken for the effective control of the quality and authenticity of such therapeutic substances offered for sale to the public as cannot be tested adequately by direct chemical means." The substances referred to are classified as follows:—A. Such products as vaccines, sera, toxins and antitoxins; B. Synthetic chemicals, such as salvarsan and its analogues; and C. Galenical and other preparations administered through the mouth, such as digitalis, strophanthus, squill, ergot, etc. Substances in A and B are not included in the British Pharmacopœia; the standardisation of those in A is left at present entirely to the manufacturer, but those in B are subject to a measure of Government control, *e.g.*, the Board of Trade issues licences for the manufacture of salvarsan, attached to which are conditions relating to maximum prices and testing by the Medical Research Council. Most of the substances in C are included in the B.P., but it is held by many that the standards therein prescribed are inadequate.

The recommendations of the Committee include the following:—Therapeutic substances which cannot be tested adequately by chemical means should be subject to supervision and control; the controlling authority to be the Committee of the Privy Council appointed under the Ministry of Health Act, 1919, assisted by an advisory committee. A central laboratory should be established under the Medical Research Council for preparing standards, conducting research, and testing samples taken from manufacturers' stocks or bought in the open market. Manufacturers should be licensed, and their plant, premises and processes inspected, but in the case of substances in B and C, inspection should be confined to the records and methods of biological testing, and, when necessary, to the filling and sealing of the containers. Similar restrictions should apply to products made abroad. Imported goods must fulfil the same conditions as to purity, etc., as home-manufactured goods; they should bear an approved form of label, and come under Section 42 of the Customs Consolidated Act of 1876. Fresh legislation would be necessary to give effect to these recommendations.

OFFICIAL TRADE INTELLIGENCE.

(*From the Board of Trade Journal for February 24 and March 3.*)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number:—

Locality of Firm or Agent.	Materials.	Reference number
South Africa	Glassware, paper	273
" ..	Druggists' sundries, disinfectants, fertilisers	274
" ..	Paint, varnish, crockery	250
Denmark	Non-ferrous metals, iron tubes ..	277
France	Industrial chemicals, drugs ..	279
"	Drugs	280
Italy	Heavy chemicals, copper sulphate, caustic soda, soda crystals, fertilisers, oils, fats ..	281
"	Chemicals, non-ferrous metals ..	282
Rumania	Sugar, olive oil, soap	283
Spain	Non-ferrous meta	284
Sweden	Paint	286
United States ..	Raw materials for paint manufacture, dyes for textiles ..	289
Mexico	Black and galvanised pipes, corrugated roofing, wall and floor tiles, sanitary ware	266
Argentina ..	Lubricating oils and greases ..	292
" ..	Earthenware	293

TARIFF, CUSTOMS, EXCISE.

Belgium.—Beet syrup may now be exported within limits to be fixed by the Ministry of Industry, Labour and Supplies.

British Guiana.—A copy of the new Preferential Customs Tariff may be seen at the Department. Among the articles that are admitted at half rates under the British Preferential Tariff are certain kinds of iron and steel, common soap, fertilisers, vermin killers, insecticides, and patent medicines containing not more than 50% of proof spirit.

British Honduras.—It is proposed to reduce the export duty on all alcoholic beverages to 5 per cent. *ad valorem.*

British India.—The tariff valuations of exported raw hides and skins have been revised with effect from February 5.

Chile.—It is proposed to exempt from increased customs duties condensed and dried milk, cocoa, sugar, petrol, and oils.

Denmark.—Import prohibitions have been removed from nitric, oxalic, and sulphuric acids, nitrates, chlorates, oxalates, perchlorates, glycerin, carbolic acid, aniline benzene, toluene, naphthalene, cymol, sulphur, phosphorus, iodine, mercury, sodium, potassium, aluminium powder, calcium phosphide, antimony sulphide, lead dioxide, and manganese dioxide.

Export prohibitions have been withdrawn from petroleum, benzine, fuel oil, and chocolate.

Egypt.—The prohibition of the import of sugar is extended to February 1, 1922.

Finland.—All exports except grain and sugar are now entirely free from licence.

Among the articles the import of which is prohibited except under licence are meat extracts, cocoa powder, chocolate, sugar, molasses, glucose, honey, saffron, vanilla, vanillin, mineral waters, silk, certain papers and paper manufactures, certain leather wares, many metal wares (except platinum wares for scientific or technical use), certain wares of porcelain, earthenware and glass, toilet soap, certain essences, and essential oils.

France.—Until further notice the export is permitted, without special authorisation of organic and chemical fertilisers, ammonium sulphate, nitrates of lime and soda, dephosphorisation slag, superphosphate of lime, calcium cyanamide, and undressed hides and skins.

Recent customs decisions affect the classification of, *inter alia*, anodes of molybdenum, artificial slates or tiles of asbestos and cement, cardboard cut for packing margarine, pneumatic tyres for side-cars, anti-friction fibres of lead impregnated with plumbago, alloys of magnesium and other common metals, artificial dolomite, lanolin, nickel, and residues of vegetable oils produced in the manufacture of edible fats.

France and Algeria.—The prohibition of the export of and the export duty on spirit of turpentine have been withdrawn as from February 12.

French West Africa.—"Coefficients of Increase" have been established on certain imports and exports, including kola nuts, sugar, alcohol, salt, silver, matches, groundnuts, palm kernels, palm oil, and gum arabic.

Germany.—The import of raw cocoa, tallow, certain oil fruits, and oil-seeds is permitted without licence.

The import and export of sulphur are permitted without licence as from February 23.

Gold Coast.—The new schedule of import duties came into force on January 22. Among the articles affected are alcoholic beverages, candles, cement, lard, lard compound, lead, matches, mineral oil, soap, and sugar. Drugs and medicinal preparations recognised by the B.P. and mineral fuel oil are admitted free of duty.

Hungary.—Among the articles on which the customs duties are temporarily suspended are sugar, molasses, colza seed, rape seed, butter, lard, goose fat, margarine, fish oil, seal oil, animal and vegetable tallow, palm oil, palm kernel oil, coconut oil, pyrites, mineral oils, lignite and schist tars, and crude lead and zinc.

Italy.—The import of crude and refined mineral oils is free from restriction, but the "sales" tax is to be maintained.

The surcharge on customs duties when paid in paper currency is fixed at 300 per cent. as from February 15.

Latvia.—Recent customs decisions affect linseed, coconut oil, edible vegetable oils, margarine, cocoa butter, and carborundum wheels.

New Zealand.—Gelatinised pigmented paper to be sensitised before use with a solution of potassium dichromate may be imported duty free under the British Preferential Tariff.

Poland.—Among the articles on which the import duty is suspended until April 1 are condensed and dried milk, margarine, fertilisers, train oil, graphite, ammonium nitrate and sulphate, Glauber's salt, sulphuric, nitric, and hydrochloric acids, dye-earths, pig iron, antimony, copper ingots, lead blocks and ingots, certain kinds of paper, and cotton wool.

The customs duty has been reduced on, *inter alia*, sugar, olein, textile leather, asbestos, ammoniacal soda, soda crystals, sodium sulphide and hydrosulphite, nitro- and amino-aromatic compounds, naphtho- and sulpho-derivatives, ether, certain metals and metal manufactures, and wood pulp. On all other goods the "agio" has been raised to 1900 per cent.

Rumania.—Export duties have been removed from carbide, carbon disulphide, calcium hypochlorite and chloride, and gypsum.

Serb-Croat-Slovene State.—The import of sugar is free from all restrictions but is subject to a "monopoly" tax of 200 dinars per 100 kg., in addition to other taxes.

Tunis.—A general sanction has been given for the export of 2250 metric tons of olive oil to foreign countries.

COMPANY NEWS.

ANGLO-PERSIAN OIL CO., LTD.—A special resolution was passed at an extraordinary meeting held on February 22 authorising, *inter alia*, (1) the conversion of the existing 6 per cent. cumulative participating preference shares into 8 per cent. cumulative non-participating first preference shares; (2) the repayment of capital to the holders thereof, in the event of liquidation, in priority to other issues, plus a minimum of 10 per cent.; (3) further issue of shares up to a maximum of £10,000,000. Sir Charles Greenway explained that the new capital was required to carry out the company's extensive programme of development. Net profits, which for the year ended March 31, 1920, amounted to £2,611,615, would not be less than £4,000,000 for the year ending on March 31 next. The company was particularly fortunate in possessing very productive wells worked at an extraordinarily low cost, and oil which contained an unusually high proportion of benzine and kerosene.

BRADFORD DYERS' ASSOCIATION, LTD.—The address of Sir Milton S. Sharp, delivered at the ordinary general meeting held on February 28, was devoted to a discussion of the general industrial situation and suggestions for improving it. The dyeing industry is most seriously affected by the great cost of coal, and the difficulties of the textile trade in this country are very much greater than in America because some 75 per cent. of our production is for export and the present state of the exchanges almost excludes the possibility of foreign trade; in the United States the ratio of exports to production is relatively very small. The profits of the Association for 1920 were slightly higher than for 1919, but owing to the necessity of meeting the depreciation in the company's investments, mainly Government securities, the total dividend for the year, 20 per cent., is 2½ per cent. less than that paid last year.

LEVER BROS., LTD.—At an extraordinary meeting held at Liverpool on February 28 it was resolved to create £15,000,000 of redeemable first mortgage debenture stock, and to make an immediate public issue of £4,000,000 of such stock. After referring to the impossibility of raising money at the present time by issuing shares, Lord Leverhulme said that during last year the company had purchased ordinary shares in the Niger Co., J. J. Crosfield and Sons, W. Gossage and Sons, Prices' Patent Candle Co., and John Knight, and, with the exception of the shares in the Niger Co., the company had realised at a profit all the stock taken over from the others. The financial assistance given to many of the associated companies made heavy calls on the company's resources, and money was also needed for the ordinary conduct of the business. The soap trade was suffering less from the prevailing depression than many other trades, but all new development work had been stopped, and until the debentures were cleared or greatly reduced the directors would not enter upon any new undertaking or acquire further capital.

COURTAULDS, LTD.—The directors' report states that the year 1920 was one of extraordinary vicissitudes; during the greater part of it business exceeded all records and the company's productive capacity was strained to the utmost, but towards the end this situation was reversed and production had to be restricted. In particular the textile department was seriously affected by the importation of foreign silk goods. During the year the share capital of the company was raised from 4 to 12 millions sterling by the capitalisation of the reserve account. Profits, after deducting all expenses and taxes, amounted to £1,804,796, which compares with £2,280,861 in 1919 and £1,184,938 in 1918. Dividends for 1920 total 12¼ per cent., free of tax, on the new capital, which is equivalent to 36¾ per cent. on the capital as in 1919, when the distribution was 30 per cent.; £200,000 is placed to reserves, against £999,993, and £383,874 is carried forward, compared with £229,077 brought in. The present value of the company's holding in the Viscose Co. is stated to exceed the valuation placed upon it in the balance-sheet. The course of business in America in 1920 was similar to that in this country, but improvement has recently set in.

GOVERNMENT ORDERS AND NOTICES.

PROHIBITED EXPORTS.—The Board of Trade (Licensing Section) announces that, as from March 1, 1921, lard has been removed from Lists A and B of Prohibited Exports. Also that the following new headings have been substituted for existing headings:—

(A) Opium and any preparation thereof containing not less than 0·2 per cent. of morphine or 0·1 per cent. of diamorphine; (A) cocaine and salts thereof, and any substance containing not less than 0·1 per cent. of cocaine; (A) diamorphine and salts thereof, and any substance containing not less than 0·1 per cent. of diamorphine; (A) ecgonine and salts thereof, and any substance containing not less than 0·1 per cent. of ecgonine; (A) morphine and salts thereof, and any substance containing not less than 0·2 per cent. of morphine.

PROJECTED NEW RESEARCH ASSOCIATIONS.—The Department of Scientific and Industrial Research notifies that the formation of associations for the jute and cast-iron industries has been approved, and that the memoranda and articles of association for two others dealing respectively with aircraft and liquid fuels for oil-engines are under consideration.

COMMITTEE ON PATENTS.—The Lord President of the Council has appointed an Inter-Departmental Committee on Patents (1) to consider the methods of dealing with inventions made by workers aided or maintained from public funds, whether such workers be engaged (a) as research workers, or (b) in some other technical capacity, so as to give a fair reward to the inventor and thus encourage further effort to secure the utilisation in industry of suitable inventions and to protect the national interest; and (2) to outline a course of procedure in respect of inventions arising out of State-aided or supported work, which shall further these aims and be suitable for adoption by all Government Departments concerned.

The sixteen members of the Committee include Mr. Kenneth Lee (chairman), Dr. H. H. Dale (Head of the Department of Biochemistry and Pharmacology, Medical Research Council), Sir Frank Heath, and the Hon. Sir Charles A. Parsons. The secretary is Mr. A. Abbott (16 and 18, Old Queen St., S.W. 1).

TRADE NOTES.

BRITISH.

Ceylon in 1919.—In spite of difficulties due to freight and rise in exchange, there was a general revival of trade in 1919. The imports, of which the U.K. supplied about 14 per cent. and British India and Burma over 54 per cent., rose in value from £11,847,784 in 1918 to £15,954,915 in 1919 (the value of the rupee being taken at 1s. 4d.). The most notable increases were in fertilisers, metals and metal-ware, and cement; of the last-named the U.K. supplied 173,119 cwt. and Japan, a keen competitor, 126,913 cwt. Exports, valued at £24,470,319, rose considerably, the chief increases being in tea, rubber, desiccated coconuts (five times the value of the export in 1918), copra, and coconut oil; the United Kingdom took over 42 per cent. and the U.S.A. over 33 per cent. (nearly double the percentage in 1918). The increase in the export of rubber, from 21,079 tons in 1918 to 44,818 t. in 1919, was partly due to stocks accumulated in 1918 owing to freight restrictions. The export of cacao decreased from 79,025 cwt. in 1918 to 54,742 cwt. in 1919, but that of cardamoms rose by nearly 50 per cent. to 561,244 lb.

In the mineral industry, there was a very sharp decline in the production of salt, the output of 319,463 cwt. comparing with 1,186,524 cwt. in the record year 1918, and representing only about half the annual consumption. Graphite mining has steadily declined since 1917, and is now at a very low ebb; 50 mines were working in 1919, compared with nearly 1300 in 1917, and the exports have decreased from over 33,000 t. in 1916 to 6671 t. in 1919. The position is viewed with anxiety, as the present slump, unlike previous slumps, is due not to lack of demand for graphite, but to supplies being obtained elsewhere. The few mines now working are producing more than the requirements, thereby adding to the existing large stocks. The attempt to revive mica mining failed, as the deposits are too small for profitable working, although some amber mica fetched good prices. The production of monazite sand on a small scale was continued at Induruwa. Materials suitable for the manufacture of Portland cement were discovered near Jaffna, and it was hoped that a cement works might be established. Sub-committees of the Industries Commission inquired into the production of hydro-electric power, for which favourable conditions are said to exist, and into glass, soap, sugar, tanning, vegetable-oil and other industries.—(*Col. Rep.—Ann., No.* 1049, *Nov.*, 1920; *U.S. Com. Rep., Jan.* 12, 1921.)

Egyptian Imports of Heavy Chemicals.—Practically all the heavy chemicals imported into Egypt are supplied by the United Kingdom, with the exception of zinc oxide, which is obtained mainly from Belgium. The imports of heavy chemicals during the first eight months of 1920 comprised:—Potassium and sodium bichromate, 202 long tons; nitrate of soda, 55,500 t.; sal ammoniac 198 t.; zinc oxide, 396 t.; caustic soda, 1500 t.; soda crystal and soda ash, 70 t.; glue, 88 t. The caustic soda imported included 33 t. from the United States, which was the only item of any importance supplied by that country.—(*U.S. Com. Rep., Feb.* 1, 1921.)

FOREIGN

The Celluloid Trade of Siam.—Celluloid goods are not manufactured in Siam, and the imports have been comparatively small during the past four years. The trade is practically in the hands of Japanese manufacturers who supplied 90 per cent. of the imports in 1919—1920, compared with 1·6 and 1·4 per cent. from the United Kingdom and the United States, respectively.—(*U.S. Com. Rep., Dec.* 31, 1921.)

Dutch Trade in Oils and Fats in 1920.—During the past year Dutch interests have acquired large holdings in German and Austrian margarine undertakings, so that in the future Holland is likely to become a clearing house for Central Europe in these trades. Although the high exchange value of the American dollar told against American exports and favoured those from Argentina, the United States nevertheless supplied four-fifths of the Dutch imports of lard, nearly all the neutral lard, about three-fourths of all other animal fats, 93 per cent. of the raw margarine, and 45 per cent. of the cottonseed oil. Difficulty was experienced in obtaining extra-quality oleo oil from the United States. Germany took 37 per cent., and Great Britain 50 per cent. of the margarine exported, and 55 and 25 per cent., respectively, of the coconut oil. —(*U.S. Com. Rep., Jan.* 26, 1921.)

Credit Organisation in the German Nitrogen Industry.—In order to encourage the purchase of nitrogenous fertilisers, the fertiliser manufacturing groups are now forming large credit organisations. It is understood that a kind of Guarantee Institute in the form of a Stickstoff-Kredit G.m.b.H. will be founded, with an original capital of 500 million marks, in which shares will be taken by the Nitrogen Syndicate and by the various associations of manufacturers, *e.g.*, the Deutsche Ammoniak-Verkaufs-Vereinigung, Bochum, the Economic Federation of German Gasworks, the Upper Silesian Coke Works, and the two firms which manufacture synthetic nitrogen products, viz., the Badische Anilin- und Soda-fabrik and the Bayerische Stickstoff-werke A.-G.

It is intended to induce farmers to purchase and accept delivery of nitrogen fertilisers in the early spring instead of in the late autumn, the Nitrogen Syndicate demanding only one-half of the purchase price on delivery, the rest to be paid by bills of exchange, which will first become due when the farmer receives the profit from his harvest. By this means no interest on the bills of exchange will be required from the nitrogen consumer for several months, and for the rest of the period he will be charged only a low rate of interest.—(*Bd. of Trade J., Mar.* 3, 1921.)

Nicaragua in 1918 and 1919.—Nicaragua, the largest of the Central American Republics, has an area of 49,200 sq. miles and a population of over 500,000. It has immense but largely undeveloped resources, including minerals (of which gold only has been worked), mahogany, dyewoods, cabinet woods, and vast stretches of uncultivated agricultural land. The production of gold, sugar, cacao, and tobacco constitute the chief industries; small amounts of soap, leather, etc., are manufactured, but only for local needs. The imports in 1918 amounted in value to £1,185,960, and included:—Cement, £4738; chemicals, drugs and medicines, £52,115; paper and manufactures of, £26,417; petroleum, £30,459. The exports, worth £1,550,988, included: Cacao, £9934; coconuts, £5460; dyewood and dyes, £2048; gold, £249,811; hides and skins, £63,266; rubber, £8523; sugar, £148,415; and silver, £45,328.

In 1919 the imports were valued at £1,582,530, of which 84 per cent. came from the United States and 9 per cent. from Great Britain; they included:—Chemicals, drugs and medicines, £89,637; cement, £6923; vegetable fibres, and manufactures of, £66,576; paper and manufactures of £31,020; petroleum, £26,087. The exports, worth £2,481,894, comprised:—Cacao, £6296; coconuts, £10,372; gold, £299,190; hides and skins, £83,748; lard, £5524; rubber, £17,181; sugar, 3847 metric tons, £123,759; and silver, £53,504; 62 per cent. of the exports went to the United States, 28 to France, and 4 to Great Britain.—(*U.S. Com. Rep., Suppl., July* 13, *Dec.* 31, 1920.)

REVIEWS.

THEORETICAL AND PRACTICAL INSTRUCTION IN ORGANIC CHEMISTRY.

A TEXT-BOOK OF ORGANIC CHEMISTRY. *By* A. F. HOLLEMAN. *Fifth English edition, edited and completely revised by* H. JAMIESON WALKER *and* O. E. MOTT. *Pp.* xviii+642. (*New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.* 1920.) *Price* 18*s.* 6*d. net.*

LABORATORY MANUAL OF ORGANIC CHEMISTRY. *By* HARRY L. FISHER. *Pp.* 331. (*J. Wiley and Sons, and Chapman and Hall.* 1920.) *Price* 12*s.* 6*d. net.*

The continuous growth of organic chemistry induces in many minds a feeling of repletion which occasionally finds utterance in a protest against the addition of further organic compounds to an already enormous list. It is sometimes pointed out that many of these substances appear to have no significance in a general purview of the subject and are often only of passing interest even to the workers who synthesise them with so much persistent industry. Yet, on the other hand, there are several classical instances of organic compounds buried in neglected corners of "Beilstein" which in the long run have proved to be substances of great practical or theoretical importance.

The aromatic arsenical derivative, atoxyl, is one example of these chemical "Cinderellas," and tri-αα-dipyridyl ferrous bromide, utlised by Werner in demonstrating the asymmetric iron atom, is another.

It cannot, however, be denied that the existence of this prodigious total of organic compounds imposes a great responsibility on those who compile a students' manual of organic chemistry, where the object in view is a concise and comprehensible presentation of the general principles of the science illustrated by a judicious selection of characteristic types of organic derivatives. The skill of the compiler is to be gauged by his choice of representative examples and by his inclusion within a reasonable compass of adequate references to all the chief divisions of the subject.

That Professor Holleman's well-known text-book has fully met this acid test is sufficiently attested by the fact that the work under review is the fifth English addition, and that 33 editions have appeared in other languages. One characteristic of this revised edition is the inclusion of a large number of data dealing with physical methods of determining the molecular complexity and constitution of organic compounds or of studying the conditions under which these substances interact with one another and with inorganic reagents.

The aliphatic compounds receive adequate treatment, but possibly some compression might be made in this section in order to allow a little more space for the discussion of aromatic derivatives. The three diaminobenzenes are aromatic bases of outstanding importance, but there is only one brief reference to ortho-phenylenediamine (p. 479) and no mention of the interaction of the diamine and nitrous acid. Yet since the production of an orthodiazoimine is the simplest way of determining the constitution of an aromatic compound containing two contiguous amino-groups, this reaction is of general interest.

In an account of the formation of the two hydroxides from crystal violet by addition of alkali (p. 545) the explanation is obscured by faulty terminology. The first product, a quaternary ammonium hydroxide, is the true colour base, and this designation should not be given to an isomeric colourless substance which is not merely a base but a carbinol. On the whole, however, the nomenclature, which has been carefully edited by the translators, conforms to the system adopted by the Chemical Society, a concordance likely to be of the greatest help to English students. The increasing difficulty of separating completely the descriptions of open-chain and cyclic compounds is exemplified by the inclusion of geraniol among the unsaturated aldehydes and ketones (p. 177), whereas it seems preferable to place this aldehyde among the terpenes (p. 525). The formula for β-naphthaquinone, which was correct in the last edition, has now become distorted (p. 558), but otherwise the treatise is remarkably free from typographical errors. The work, which has been thoroughly brought up to date, is to be recommended strongly as an unerring guide to modern organic chemistry.

Although "organic preps." are for many students the most attractive section of practical chemistry, it is doubtful whether they inculcate sufficiently those habits of tidiness, accuracy, and practical dexterity which are the best foundation of a training in the laboratory arts. When carried out in a casual and thoughtless manner, organic preparations become merely a hedonistic pastime without the mental and moral training gained in a course of chemical analysis. This danger has evidently been in the mind of Dr. H. L. Fisher in devising his course of laboratory experiments in organic chemistry, for he lays great stress on the accurate determination of carbon, hydrogen, and nitrogen in organic compounds. The author traces the gradual evolution of these methods of organic analysis, to which he has added important developments. He favours the use of an electrically heated furnace both for carbon and hydrogen estimations and for the determination of nitrogen. His employment of alumina as the absorbent for water in place of calcium chloride or concentrated sulphuric acid is an improvement likely to come into general use. These descriptions of the analytical processes occupy about one-third of the book, and attention paid to these very practical details will certainly conduce to success in organic estimations. The remainder of the treatise is devoted to laboratory experiments, including the preparation of a typical series of organic compounds, exercises on distillation, and precise determinations of melting and boiling points. The "quizzes" which form such a characteristic feature of American teaching are very much in evidence at the end of each experiment. The student who tries conscientiously to answer all these searching questions will, by the end of the course, have gathered a very considerable fund of information regarding the nature and behaviour of organic substances. The book includes many references to original literature and to other text-books. Certain of the exercises suggested are somewhat off the beaten track. such as the hydrolysis of butter, the preparation of lecithin and *l*-menthone, and several typical syntheses in the camphor series. These innovations are a welcome change from the more stereotyped preparations and lend additional interest to an original and inspiring manual of practical chemistry.

G. T. MORGAN.

THE TESTING OF DYESTUFFS IN THE LABORATORY. *By* C. M. WHITTAKER. *Pp.* 100. (*London: Heywood and Co., Ltd.* 1921.) *Price* 12*s.* 6*d. net.*

Although there were already numerous text-books on dyeing in existence, there has not previously been a treatise dealing with the subject so thoroughly from the point of view of the laboratory dyer. This book will undoubtedly be of great value to those engaged in experimental dyeing on a laboratory scale, and also to those who have to interpret the results obtained in the laboratory.

The first chapter deals in an excellent manner with the equipment and functions of a dyeing

laboratory, and contains a large amount of information based on the author's twenty years' experience. The next seven chapters deal with the dyeing of various classes of dyestuffs in the laboratory, and also with the tests to which the dyeings should be subjected and the results which may reasonably be expected. The treatment is fairly full and eminently practical. A useful chapter on the dyeing of mixed fabrics and a final chapter containing miscellaneous information follow. A series of tables and a full index complete the book.

It is unfortunate that more care has not been given to a revision of the English used in this book, particularly in view of the critical review of the author's previous book (*cf.* J., 1919, 38, 35 R). A sentence such as "Enter the material cold, raise carefully to boil in half-hour, and dye at the boil half-hour" (p. 11), may be satisfactory in a laboratory note-book, but it should not be allowed to appear in a work of this nature. Again, it is interesting to note that "The water in the dyebath should have had the oxygen taken out of it by adding hydrosulphite powder conc. . . . ." (p. 63). Another notable point is the failure of the author to use hyphenated words, which leads to the frequent occurrence in the text of such words as "dyetest." In other parts of the book, the language used is certainly forcible, but by no means elegant. A point of a different character is that the author fails to emphasise sufficiently the necessity of using a freshly-prepared dye-bath as a standard in dyeing most of the anthraquinone vat-colours.

The book is essentially practical, and should be in the hands of all who wish to be acquainted with the peculiar technique of the laboratory testing of dyestuffs.

F. W. Atack.

A System of Physical Chemistry. *By* W. C. McC. Lewis. Vol. II., Thermodynamics. *Third edition. Textbooks of Physical Chemistry. Pp.* viii.+454. *(London: Longmans, Green and Co.* 1920.) *Price* 15*s. net.*

The importance of thermodynamics in many branches of industrial chemistry is now admitted; the work of Haber on the synthesis of ammonia is but one of the recent highly successful researches undertaken with an understanding of this branch of physical chemistry. The records of technical chemistry contain more than one example of costly blunders which could have been avoided by an elementary knowledge of thermodynamics.

The applications of thermodynamics to chemistry are so peculiar and specialised that a distinct treatment is necessary; a book written from the engineering standpoint is of little service to the chemist. The difficulties of acquiring a knowledge of the science have been greatly exaggerated and perpetuated by tradition among chemists. Two methods of treatment suggest themselves. Either particular attention is paid to general principles, their meaning and fields of application being considered broadly, or else the fundamental laws and equations are regarded as something to be got over as quickly and painlessly as possible, so that after a little mental leapfrog the far-reaching fields of special applications are entered and the consideration of details begun.

Prof. Lewis has perhaps tended to go too lightly over the fundamental parts of the subject. He has treated a large mass of detailed applications in some cases less critically than he might with advantage have done. In the lengthy discussion of Tinker's contribution to the theory of osmotic pressure, for example, he might well have pointed out that the application to intermolecular volumes of equations deduced for matter in bulk is outside the region of legitimate application of these equations. In the summary of recent American work on solutions (which is presented without any attempt to connect it with the rest of the book), the reader might have been informed that it is impossible by a really legitimate use of thermodynamics to arrive from the same set of data at two diametrically opposite conclusions.

The sections on electrochemistry, affinity, and Nernst's heat theorem are the most satisfactory parts of the book, and these should appeal especially to technical chemists. A fair knowledge of the calculus is naturally assumed, and all chemists who are so equipped will find Prof. Lewis's book both interesting and useful. Thermodynamics is not of purely academic interest, as the Haber factories in Germany eloquently testify.

THE HABER PROCESS AT OPPAU.

J. R. PARTINGTON.

The synthetic ammonia plant of the Badische Company comprises two factories: the Oppau works, forming practically a continuation of the parent works at Leverkusen, and the Leuna works near Merseburg (Halle). Oppau, which is said to have cost £15,000,000, was commenced in 1913, with a capacity of 20 tons of ammonia per day; during the war this was increased to 200 tons. The synthetic nitrogen products made at Oppau in 1918 are stated to have been:—

	Tons per annum.	NH_3 equivalent.
Ammonium nitrate	10,000 ..	4,250
Sodium nitrate..	130,000 ..	26,000
Nitric acid	40,000 ..	10,800
Ammonia liquor*	— ..	40,000

* Exported to Höchst for oxidation to nitric acid.

The Leuna works was erected since 1916, and has a capacity of 400 tons of ammonia daily. The combined output of Oppau and Leuna, 210,000 tons of ammonia per annum, is equivalent to over 800,000 tons of ammonium sulphate or 1,050,000 tons of sodium nitrate. Importation of the latter by Germany is no longer necessary. The German Minister of the Interior reported that Germany in 1916 made, by all processes, 400,000 tons of synthetic fixed nitrogen. Besides synthetic ammonia other salts, such as the chloride and nitrate, and mixed salts for fertilisers, are made at the Haber factories.

The power for both plants is derived from lignite. That for the Oppau works comes from the Ruhr district. The fuel is gasified in "Bamag" producers, 12 ft. by 25 ft., with rotary grates, a little steam being added to the air. In the Oppau works (to which the following description applies) the power plant generates 15,000—16,000 h.p. A row of 12 gas producers, each consuming 20 tons of lignite and yielding 2 million cb. ft. of gas per day, is built alongside a similar row of water-gas generators which provide the hydrogen. The latter use Ruhr oven-coke, are of the Pintsch type with rotary grates, 15 ft. by 25 ft., gasifying over 30 tons of coke to 3,000,000 cb. ft. of gas each daily. Some air is added, and the resulting gas contains about 40% H_2, 30% CO, 12% CO_2 and 18% N_2. The water gas is treated by the Badische process (B.P. 26,770 of 1912; 27,117 of 1912; 124,760 of 1918; U.S.P. 1,115,776 of 1914; 1,200,805 of 1916), in which a mixture of water-gas and steam is passed over a catalyst consisting of ferric oxide, with promoters such as chromium oxide, at a temperature of 400—500° C., when the reaction $CO+H_2O \rightleftarrows CO_2+H_2$ takes place. The catalyst remains active for two years. The catalyst plant comprises 24 units in two sections of two rows of 6 to 7 units. Each unit has two heat-exchangers and one elevated catalyst chamber; the latter is 16 ft. by 12 ft. by 10 ft. deep, with an oval cover carrying two 8-in. pipes, and contains two trays of catalyst. The heat-exchangers are 30 ft. by 15 ft. by 6 ft., and the whole apparatus is lagged, so that the reaction takes place without external heating. (The addition of a little oxygen or air to the gas has been described as a means of maintaining the temperature, a free flame burning in the catalyst chamber.) The gas issuing from the converters (in which the reaction is conducted at atmospheric pressure) contains a little carbon monoxide (according to Greenwood, "Industrial Gases," p. 163, this may be 2·5%), and must be purified from carbon dioxide, residual carbon monoxide, and hydrogen sulphide (from sulphur in the coke).

The purification (B.P. 120,546 of 1914; 9271 of 1914; 120,546 of 1918; F.P. 389,671 of 1916; U.S.P. 1,196,101 of 1916) is carried out by washing out the carbon dioxide with water under pressure (B.P. 11,878 of 1910; 124,761 of 1918); washing finally with soda (B.P. 15,053 of 1914) is not used. Carbon monoxide is taken out by washing with ammoniacal copper solution and hot caustic soda solution under high pressure (B.P. 1759 of 1912; U.S.P. 1,126,371 of 1915; 1,133,087 of 1915; J. Amer. Chem. Soc., 1921, 43, 1), which also takes out hydrogen sulphide. The copper solution contains excess of ammonia (not less than 6%) to prevent iron being attacked; the soda solution may contain 25% NaOH, and is brought in contact with the gas at 260° C. under 200 atm. pressure.

In the purification from carbon dioxide the gas, carried by a 3 ft. main from the converters, is compressed at 25 atm. and passed to the bases of eight steel towers, 30 ft. by 4 ft., packed with rings, into the tops of which water at 25 atm. pressure is injected by circulating pumps. The water issues charged with carbon dioxide; it is passed through Pelton wheels, in which 60 per cent. of the power is recovered, and the carbon dioxide evolved is collected. It is important that the amount of carbon dioxide recovered should be more than sufficient to convert all the ammonia produced into sulphate by the gypsum process, or into chloride by the ammonia-soda process. The gas is now passed through steel bottles which act as spray catchers to the high-pressure plant. Here it is brought to 200 atm. and delivered to the carbon-monoxide purifiers.

This plant consists of 16 towers of special steel, each in one piece, 25—30 ft. high by 2 ft. 6 in. external diameter, with flanged ends, and packed with Guttmann balls. In the first eight of these an ammoniacal copper formate solution is circulated, in the remainder caustic soda ($CO+NaOH=H.COONa$). The liquids are circulated by eight hydraulic pumps of forged steel, 200 h.-p. total, and the ammoniacal copper solution, which absorbs ten times its volume of carbon monoxide, is passed down a 40 ft. tower, where the gas is released and collected. Spray traps in the form of vertical steel bottles are placed under these towers. The presence of 0·01 per cent. of carbon monoxide in the final gas is said to be injurious.

The purified hydrogen (with some nitrogen from the air mixed in the water-gas operation) is now passed to the catalyst plant by a high-pressure main. The nitrogen content is brought up to the ratio $N_2:3H_2$ from a Linde plant, and the gas is dried.

The catalyst plant, in which the mixture is converted into ammonia, consists of fifteen steel bombs, each comprising two straight flanged sections, each 19·7 ft. long and 31·5 in. internal diameter, the walls being 7 in. thick. These are bolted together and the covers are held on by fifteen 4-in. studs. The walls are perforated at intervals of 1 ft. with ½-in. tapering holes. Inside is a steel liner, making a gas-tight joint with the ends (U.S.P. 1,188,530 of 1916; D.R.P. 254,571 and 256,296 of 1911), and probably also a refractory lagging and a support for the catalyst, the internal diameter of the catalyst space being 19·75 in. The outer walls are heavily lagged, and reach 300—400° C.; the catalyst is at 600° C. The temperature is maintained by heat-exchangers, consisting of forged steel tubes, 19·7 ft. long and 15 in. external diameter, fitted internally with nests of ⅜-in. steel tubes autogenously welded into end-plates. Each catalyst unit (costing 100,000 marks) is mounted vertically with its heat-exchanger inside a brickwork compartment with strong iron doors and planking, with a little of the bomb projecting above. Starting is effected by

adding oxygen (which does not come into contact with the catalyst) (D.R.P. 359,870 of 1911) or by electrical heating (U.S.P. 1,202,995 of 1916). An iron catalyst with a promoter (possibly molybdenum) is used (D.R.P. 265,295 of 1912; U.S.P. 1,188,530 of 1916).

The gas is circulated through the catalyst; argon and methane may accumulate up to several per cent.; 10 per cent. of the gas is lost by leakage.

The ammonia is removed from the gas by solution in water under pressure (D.R.P. 235,421 of 1908; 270,192 of 1912); liquefaction (U.S.P. 1,202,995 of 1916) is not economical. Three water-injector pumps are connected with nine sets of absorbers, each consisting of three water-cooled steel spirals set vertically, the upper spiral being 60 ft. above ground. The gas passes down the lowest spiral, rises to the top of the second spiral and passes down this; and similarly with the third spiral. Water flows down all the spirals by gravity. A solution containing 25% NH_3 is obtained. The gas is dried and sent back to the catalyst system.

The personnel at Oppau comprises 1500 labourers, 3000 mechanics, 350 clerks and 350 chemists. The fuel requirements (McConnell, J. Ind. Eng. Chem., 1919, **11**, 837) are 1750 tons of lignite (400 for gas engines, 1000 for steam for hydrogen plant and 350 for power plant) and 500 tons of coke (for hydrogen) per day. The daily cost of labour is £2300, of fuel £2300, and working expenses, interest, etc., £6700. The progress made since the laboratory experiments of 1906 to this immense factory in 1913—a period of only seven years—represents one of the greatest technical achievements of all time. Of particular interest is the association of the synthetic ammonia plant with the ammonia soda process.

* * *

The only other synthetic-ammonia factory outside Germany is the United States Nitrate Factory No. 1, at Sheffield, Alabama, erected during the war. This utilises the modified Haber process of the General Chemical Co. (U.S.P. 1,141,947—8 of 1915; B.P. 120,546 of 1918; 124,760—2 of 1918). The catalyst is prepared by impregnating pumice with nickel or ferric nitrate, heating to 550° C., reducing at this temperature with hydrogen, and treating with sodium and ammonia gas at 450° C. Sodamide is formed in the spongy metal, and the mass acts at 500° C. under 70 atm. (a much lower pressure than that used in Germany). The plant was designed to produce 21·5 tons of ammonia daily, and cost $13,000,000; the synthetic ammonia section cost $7,000,000, but requires another million for completion. Three units are installed. The plant was operated for a short time, but great difficulties were encountered owing to faulty design, and the factory was closed in the beginning of 1919, about three months after work began. The process developed into a straight blue water-gas make, followed by addition of air in the hydrogen converters for flame combustion to maintain the temperature. Caustic scrubbing was discarded as giving too much sediment and ammoniacal cuprous carbonate alone used at low temperatures. The catalyst furnaces, which were operated at 100 atm., were similar to the well-known Badische converters for sulphur trioxide, but much thicker and capable of withstanding pressure. The catalyst was contained in the internal battery of iron tubes. Self-heating was not attained (R. S. Tour, J. Ind. Eng. Chem., 1920, **12**, 844).

APPOINTMENT OF COMMITTEE UNDER THE DANGEROUS DRUGS ACT.—The Home Secretary has appointed a committee of five to consider objections to, and to advise concerning possible modification of, the draft Regulations issued under the Dangerous Drugs Act.

THE MANUFACTURE OF HAND-MADE FILTER PAPER.

J. BARCHAM GREEN.

The following brief notes on the manufacture of hand-made filter paper will be of interest in view of the circumstances that the manufacture was practically initiated in this country during the war, and that English papers have now to a great extent replaced the foreign-made papers which were previously in general use.

The foundation of a good paper is suitable rag; old muslin curtains have been found to give the best results for fast filtration, but where strength is required a strong rag, like best canvas or old linen shirts, is often added. After the rags have been sorted and cut by hand the dust is shaken out in a rotary machine made of wire gauze, then buttons and other foreign matter are picked out, and the rag is boiled with alkali for 1 to 4 hours. Opinions differ as to whether alkali should be used, but 2 to 3 lb. per cwt. of dry rag should not be harmful if the boiling is done without high pressure. The boiled rag is reduced to pulp in water in a beater provided with bronze knives fitted on to a solid drum, which can be lowered until the knives touch a grooved bronze plate. Paper that filters quickly is obtained by reducing the proportion of rag to water and increasing the speed of the beating, but much depends on the skill with which the roll or cylinder is adjusted to the grooved plate; when the beating has been done very quickly the finished sheet will sometimes show the threads of the muslin rag used. The pulp is usually bleached with chloride of lime, the excess of which must be completely washed out with pure water. After beating, the pulp is strained to remove knots and lumps, run over magnetic separators to remove any particles of iron that may be present, mixed with water, and then run into a vat, either of stone or of iron lined with lead. A layer of pulp is obtained by dipping a mould covered with wire gauze into the vat, removing it and allowing the water to run off; the layer is pressed on to a felt and a pile of alternate layers of pulp and felt is put under a hydraulic press. The pressure applied largely determines the texture of the paper; if it be too great a hard paper that filters slowly will be produced. The paper is dried either on a steam-heated cylinder or by hot air, sorted, and stocked as sheets or circles. Circles are cut from a wad of about 100 sheets by means of a steel cutter, and when large circles of, say, 50 cm. diameter are cut from a sheet of 50 cm. square, the corners are wasted if they cannot be sold. This explains why the price of circles is apparently out of proportion to their actual size.

In the manufacture of filter paper particular attention has to be paid to its purity, strength, filtering speed, and ash content. To obtain a pure paper neutral spring water, free from organic matter and containing little calcium bicarbonate, must be used. When testing for strength the paper must be wet; the strength when dry is often very different from the strength when wet, especially in the case of very strong papers intended for use with a filter pump.

Roughly speaking, the stronger a paper the more slowly it filters, and to obviate this difficulty the manufacturer selects a very strong fibre, such as new linen, and beats it very rapidly to a pulp; otherwise it becomes slimy (if beaten long enough it would be converted into hydrocellulose and produce a sheet of parchment which would be waterproof). Strength can also be obtained by using thicker paper, but as this filters slowly some makers produce a paper with a crinkled surface. Such a surface cannot be given to hand-made papers, but a better result is obtained by folding the paper fan-

wise to produce a fluted surface. The speed of filtration is ascertained by finding the time required for pure water to pass through the paper at a definite temperature. Liquids containing suspended solids, such as barium sulphate, are less suitable, as mistakes may be made in preparing them; they must, however, be used in testing the clarity of the filtrate.

Before the war certain foreign firms sold "ashless" papers having a certain ash content, and their figures were usually taken as correct; but when the manufacture was started in this country it was found that the ash content of these papers varied very greatly and that it was seldom as low as the figure stated. English papers, as now made, usually contain a little less ash than is indicated on the wrapping. English manufacturers now produce a large variety of papers among which types can be found suitable for many special purposes; and the makers are usually prepared to satisfy individual requirements. Complaints of bad quality often arise from the use of papers for purposes for which they are unsuited; they could in most cases be avoided by careful reference to the manufacturer's catalogue before purchasing.

THE MANUFACTURE OF SULPHURIC ACID IN THE UNITED STATES.

Bulletin 184, recently issued by the U.S. Bureau of Mines, contains a considerable amount of information relating to the manufacure of sulphuric acid in the States. In 1865 only some 37,500 tons of acid, calculated as 100 per cent., was manufactured; in 1880 this had become 265,630 tons, and in 1900 over one million tons. The table which follows gives the production for the last six years before the armistice. It should be noted that all quantities have been calculated into the equivalent of 100 per cent. acid, as in the report different ways of stating the strength are given:—

Year.	Concentrated acid produced as 66° B. Tons.	Total production a strengths calculated to 100% H_2SO_4. Tons.
1913	810,000	2,239,930
1914	720,000	2,280,000
1915	1,160,000	3,173,800
1916	1,930,000	3,938,000
1917	2,100,000	4,505,000
1918	2,400,000	4,661,300

Towards the end of 1918 the producing capacity was approximately 6 million tons, about 40 per cent. of the total being contact acid. Government and explosive manufacturers' plants accounted for about 22 per cent. of the total production, the rest being fertiliser and general chemical works plants. When the armistice was signed work was stopped at once on plant in course of erection designed to produce some 450,000 tons per annum.

The distribution of the factories is described by means of a map, tables and a list of the individual works, the greater number being in the Eastern and South-eastern States.

The proportion in which the various industries were using acid in 1918 is shown below:—

	Per cent.
Explosives (military)	33·5
do. (domestic)	2·5
Fertilisers (superphosphates)	28·4
Oil refineries	8·8
Chemicals, drugs, and ammonium sulphate	9·9
Steel pickling and galvanising	9·3
Fabrics, textiles, etc.	1·3
Paints, lithopone, glue, etc.	1·4
Metallurgical, including storage batteries	3·9
Miscellaneous	1·0
	100·0

The normal requirements of the United States are estimated to be equivalent to about three and a half million tons of 100 per cent. acid, of which about one-half is required for superphosphates, so that a considerable margin of producing capacity exists.

The influence of the war on the proportions of the various sources of sulphur as raw material is well illustrated in the next table:—

	Percentage of total quantity. 1914.	1917.	1918.
Brimstone	2·6	32·6	48·0
Pyrites (Spanish)	50·0	22·9	7·6
do. (domestic, including coal brasses and pyrrhotite)	15·8	11·8	12·7
do. (Canadian)	7·9	6·9	7·5
Zinc ores	13·2	18·1	16·1
Waste gas from copper smelters	10·5	7·7	8·1
	100·0	100·0	100·0

Practically all the brimstone was obtained by the Frasch process of mining from the coastal plain deposits of Louisiana and Texas. Owing to the ease of handling and to the cleaner gas obtained, brimstone is considered to be worth 3 to 4 cents more per unit than a 40 per cent. pyrites if the acid maker gets nothing for his burnt ore. The price of Spanish pyrites rose during the war to as much as 30—35 cents per unit, but it has since fallen again, the quotation in July last being 16 cents. Much attention has been given to the recovery of pyrites from waste coal, and it is concluded that the coal mines of the Eastern States could produce over 1½ million tons of pyrites per year with an average content of 40% sulphur.

All the zinc works of Illinois, Indiana, Ohio, Pennsylvania, and West Virginia are producing acid, but those of Kansas, Missouri, and Oklahoma have not yet done so. At the copper works some very large plants exist, that of the Tennessee Copper Co. being capable of producing acid equivalent to over 625 tons (of 100%) per day.

Both the chamber and the contact systems are described at considerable length, and the following are the chief points noticeable about the American practice:—Owing to the large use of brimstone, special devices for burning this material have been developed, among which may be mentioned the Tromblee and Paul rotary and the Vesuvius vertical burners; Herreshoff and Wedge types of mechanical fine pyrites roasters seem to be most in favour, and Hegeler, Spirlet, and Wedge (muffled) are in use for zinc ores. The Cottrell electrical precipitator has given satisfaction both as a dust eliminator for burner gas and as a condenser for fumes from acid-concentration plants. Towers constructed of acid-proof brick and cement without a lead casing are in use, and steel framing is replacing wood as a material for supporting the chambers. Much attention appears to be given to intermediate towers of various types, and a full description is given of the "Anaconda Packed Cell" system, in which the chambers are replaced by towers packed with special tiles.

In metallurgical and other works where the composition of the burner gas is likely to vary the Fairlie system of analytical control is advocated. Concentration is effected in cascades, Kessler plants, and in tower systems of local design, such as the Kalbperry and the Chemico Concentrators, but no mention appears to be made of the Gailliard system. The Mannheim, Badische, Grillo-Schroeder, and Tentelew contact systems are all in use and are described and compared, as are also the various types of gas-cooling towers, dust filters, drying and absorbing systems, and the methods of preparing and revivifying the catalysts.

Comparisons of pre-war and post-war costs of plant and acid for both chamber and contact systems are given, and the report concludes with a short account of the methods of utilising burnt pyrites and nitre cake.

SOCIETY OF CHEMICAL INDUSTRY.

ANNUAL MEETING, 1921.

With reference to the cancelled sailing of the s.s. "Megantic" from Liverpool to Montreal on August 13, it has been decided to postpone for another month the choice of the steamship to convey the presidential party.

The following communication has been received from the Committee of the Montreal Section:—

Plans are rapidly maturing for the Annual Meeting of the Society to be held in the latter part of August. A strong committee of the Montreal Section is arranging an elaborate programme of great interest to visiting members, details of which will be announced later. The Windsor Hotel, situated in the upper heights of the city of Montreal, one of the beauty spots of the Canadian metropolis, has been chosen as headquarters. A unique feature of Montreal is the glimpses it affords of the old French *régime* side by side with examples of the modern spirit of commercialism, *e.g.*, the historic Bonsecours Church with its immense statue overlooking one of the world's most modern harbours, where huge grain elevators give evidence of one of the main sources of the country's wealth. Plans are being made for an extended trip in Canada which will provide opportunities to inspect typical Canadian manufactures and to view the primitive beauty of forest and stream. As the steamships plying between England and Montreal touch at Quebec, a few enjoyable hours may be spent in rambling round the ancient capital and its environs so rich in historic interest. It is considered none too early for members to begin making their plans with a view to attending what should prove to be a particularly interesting meeting.

MARCH MEETING OF COUNCIL.

At the monthly meeting held on March 11, the President moved a vote of condolence to the family of the late Lord Moulton, which was carried unanimously, and the Secretary was asked to attend the memorial service. Sir William Pope intimated that the nomination of the president for 1921–22 would be considered at the next meeting, also the nomination of vice-presidents and the election of hon. treasurer and hon. foreign secretary. Thirty-nine new members were elected (21 home, 4 colonial, 3 Indian, and 11 foreign), and Mr. John Spiller, an original member who has done valuable work for the Society over a long period of years, was unanimously elected an honorary life member.

The Hon. Treasurer reported that the sum of £13,124 had been received as proceeds of the realisation of the non-trustee securities of the late Dr. Messel's bequest, and it was resolved to invest the whole of this sum in 5 per cent. War Loan, 1929–47. It was also stated that the Finance Committee would in due course prepare a statement showing how the legacy had been dealt with. A separate account will be kept of the monies derived from this bequest.

On the report of the Publications Committee, it was decided to authorise the reprinting and circulation of approved articles from the Review bearing upon public policy, as occasion required and due regard being paid to expense; and it was agreed that the Council, through the Government and Parliamentary Committee, should associate itself with the Pharmaceutical Society and other interested bodies in opposing the regulations recently issued under the Dangerous Drugs Act. The report of the Edinburgh and East of Scotland Section was presented to the Council.

CHEMICAL ENGINEERING GROUP.

A conference on "Waste Waters" was held at the Technical College, Huddersfield, on February 24. Dr. H. H. Hodgson, who presided in the absence, through illness, of Mr. J. A. Reavell, commented upon the importance of the work done by the Society and the Group in spreading useful knowledge applicable to the development of industry, and complimented the Group upon its enterprise in holding its meetings in various parts of the country instead of in one locality, as was the practice of many societies. He then called upon Mr. E. V. Chambers to read his paper on "Plant for the Purification of Industrial Waste Waters, with Recovery of Useful By-products."

The woollen industry yields three classes of effluent—that from washing the raw wool, that from scouring yarn and pieces, and the effluent from the dyeing process. In each case the effluent is passed through a rotating circular screen to remove fibre, and the subsequent treatment, which is partly mechanical and partly physical, varies with the nature of the liquid to be purified. Suspended solids are eliminated in settling tanks by gravity or centrifugal filters, and colloidal matter is similarly removed after pre-treatment of the liquor with alumino-ferric or other precipitant. The author then described—first generally, then in detail—the process for purifying the effluent from a woollen piece-scouring factory, which consists, briefly, in removing the grease by saponification with alkali, and then treating the liquor for recovery of soap, soda, and oil. A typical plant with a capacity of 22,000 galls. a day of strong scouring liquor was described and illustrated. The next portion of the paper dealt with the treatment of general effluent to produce a non-polluting discharge into a stream. In its broad outlines the scheme is the same as that mentioned above, but additional factors have to be taken into account, and labour charges must be cut down to a minimum. A good example of the feasibility of conducting effluent treatment as a source of profit is shown by the recovery of wool grease, lanolin, and potash from wool scourings; it is estimated that nearly 50,000 tons per annum of wool fat and about 20,000 tons of potash (reckoned as carbonate) are available for recovery in this country. The successful Smith-Leach process was described and also the modern centrifugal method which yields wool fat of twice the value and at half the cost of the "acid" or chemical process. Details were given and photographs and diagrams shown of a plant for carrying out the centrifugal process. The treatment of the pickling liquor obtained in various metal-working factories, *e.g.*, wire-drawing works, where it contains about 0·5 per cent. by weight of free hydrochloric acid and about 20 per cent. of ferrous chloride, consists in adding enough sulphuric acid to liberate all the combined chlorine as hydrochloric acid and in obtaining this by distillation, the iron being recovered as ferrous sulphate. The operation of a typical plant was described and explained.

Mr. O. Reynard, of Bradford, said that he had found that the centrifugal method of extracting wool fat was very successful from the qualititative standpoint, but that he had only been able to recover about 40 per cent. of the fat instead of 60—75 per cent., as mentioned by the author. The difficulty probably lay in the existence in the emulsion of the wool fat in two states of "fineness"; the coarser was rapidly removed and represented the 40 per cent. extraction, but the finer could not be completely separated. Mr. Chambers, in his reply to Mr. Reynard and others, said that the results given in his paper had mostly been obtained on a commercial scale at works in Huddersfield. The "frothing" process had been tried but had invariably led to bacterial decomposition of the wool

fat unless the air had been sterilised or filtered before use. The "churn" process had also been experimented with, but it was only partially successful and far less effective than the methods described in the paper. No trouble had yet been experienced from the presence of arsenic in the acid recovered from waste pickling liquor (*cf. s.*), as the design of the plant obviated this.

The full report of the meeting will be published in Volume III of the *Proceedings* of the Group.

NEWS FROM THE SECTIONS.

TORONTO.

"The Story of Petroleum" was the subject of an address delivered by Mr. W. A. P. Schorman, of the British-American Oil Co., on January 28. The chairman of the Section, Mr. M. L. Davies, of the Standard Chemical Co., presided, and there was a very large attendance of members and visitors. The address was illustrated by kinematograph pictures showing the activities of the oil industry from the drilling and shooting of the oil wells to the distillation processes in the refineries. Referring to the recent discovery of oil at Fort Norman in North-West Canada, Mr. Schorman said that he believed that oil had been found there in paying quantities, but actual figures were not yet available. The oil that had been found would flow freely at a temperature well below $-60°$ F. and did not solidify above $-90°$ F. This was a very valuable characteristic of the oil, for the temperature in that territory often reached $-60°$ F. during the winter. Another very valuable circumstance was that the oil yielded over 50 per cent. of the lighter hydrocarbons, so that when the territory was sufficiently developed a large supply of gasoline should be secured. The discovery of the oilfield was made by a Canadian geologist, Mr. Boswell. Mr. C. B. Parsons, president of the British-American Oil Co., spoke optimistically of the development of the oil industry in Canada, and expressed his belief that oil would yet be found in other more accessible parts of the Dominion. The need for developing an oil industry in Canada was very great.

OTTAWA.

On December 16, 1920, about 40 members of the Section assembled to see a kinematograph film entitled "The Story of Coal," kindly lent by the Sullivan Machinery Co., of Chicago. The film showed the mining of coal in one of the model mines in Pennsylvania and many views of plant used in manufacturing mining machinery.

At a meeting in the Carnegie Library, Ottawa, on January 13, Mr. E. Stansfield presiding, a discussion arose on the Bill to be introduced in the Ontario Legislative dealing with the legal status of the engineering profession, and it was decided to convene a meeting of the chemists of Ottawa to discuss the subject more fully. Dr. R. S. Stevens then gave an address on "Vitamins" in which he traced the history of the development of this branch of biochemistry and summarised our present knowledge of the subject. Colonel J. T. Janson followed with an address on the more chemical aspects of these food factors. Sixty-five members and guests were present at this meeting, including medical men and representatives from the University Women's Club.

A joint meeting was held with the Engineering Institute of Canada on February 10, the chair being taken successively by Lt.-Com. C. P. Edwards, chairman of the Ottawa Branch of the Engineering Institute, and Mr. E. Stansfield, chairman of the Section. The attendance numbered 65. Capt. E. M. Dawson read a paper in which he reviewed the cement industry and described recent work on super-cements. He outlined the processes involved in the manufacture of Portland cement, dealt more in detail with the methods of testing raw materials and products, and finally reviewed the improved methods of making cement involving the use of what he termed "cata-cell," a substance which is introduced into all super-cements. He claimed that super-cement is superior in every way to Portland cement, because it is waterproof and more durable, owing to the fact that a "cata-cell" promotes more complete hydration. A long discussion followed.

LONDON.

A meeting of the London Section was held at Burlington House on March 7, Mr. Julian L. Baker presiding. Two papers were presented, the first of which was by Dr. J. C. Drummond on "Factors Influencing the Food Value of Lard and Lard Substitutes." It has often been stated that animal fats contain the fat-soluble vitamin A, and that vegetable fats are deficient in this substance; no such general rule, however, can be laid down since it has not hitherto been identified in lard. Two causes contribute to the low vitamin content of lard:—(1) The diet usually given to pigs in this country is often deficient in vitamin A; and (2) during the process of lard manufacture much of the vitamin, if present, is destroyed owing to exposure of the fat to oxygen at high temperature. If pigs are fed with a material rich in vitamin, such as grass or cod-liver oil, not only do they grow much better, but their fat contains plenty of this important factor. It would appear that the destruction of the vitamin is due less to the high temperature to which the fat is subjected in the subsequent refinement of the lard than to the action of atmospheric oxygen.

The second paper, entitled "The Stability of Benzoyl Peroxide," was read by Dr. R. C. Farmer. Benzoyl peroxide is of industrial interest as an oxidising agent, and has been used for several purposes under the name of "Lucidol." It is a powerful antiseptic, and has been used for the treatment of burns and ulcers. It acts as a drier for linseed and other drying oils, and has been used to a small extent as an explosive. The substance is unstable whether it be crude or pure, but immunity against explosion can be attained by mixing it in the wet condition with excess of salt and then drying.

NEWCASTLE.

At a joint meeting of the Section with the Cleveland Institution of Engineers, held at Middlesbrough on March 7, Mr. C. F. Tidman, in a paper on "Alcohol from Coke-oven Gas," described further experiments which had been carried out at Skinningrove on the absorption of ethylene by sulphuric acid and its conversion into alcohol.

In a brief historical introduction it was stated that Hennell had published papers in 1827-28 on the production of alcohol from ethylene, and that he therefore deserved to rank with Wöhler as the first to produce an organic compound from inorganic constituents. A series of laboratory experiments was described which showed that the ethylene was most rapidly absorbed by sulphuric acid of 95·4% at about 80° C. with turbulent contact; and it was deduced that nine towers, each 10 ft. diam. by 80 ft. high, would be required for the absorption of the ethylene contained in the coke-oven gas at Skinningrove, where 800 tons of coal are carbonised daily; of these nine towers the volume of six would be occupied by packing material. In further laboratory experiments it was observed that when ethylene and sulphuric acid are shaken in a flask, the addition of silica increases the absorption by about 5 per cent.; and it was concluded that whether

absorption towers or mechanical washers be adopted for large-scale use, it should be possible to remove 70—80 per cent. of ethylene from the coke-oven gas by allowing a contact of 2½—3 minutes between it and the sulphuric acid. Mr. E. Bury found that 18 per cent. of the sulphuric acid put into circulation was available for ethylene-absorption, *i.e.*, that a 95% acid would continue to absorb until its concentration was reduced to 77%; further work has shown that the absorption can be carried still further when a mechanical agitator is used. The great advantage of a mechanical washer over a tower-scrubber system is the much smaller size of the plant required.

The recovery of the alcohol from the reaction mixture was found to be best effected by distillation with steam under reduced pressure, the bulk of the alcohol being obtained as a 15% concentrate. After rectifying up to 87%, it gave good results when used as motor fuel. The alcohol obtained by this method contains various impurities, including diethylene disulphide and a yellow oil of unknown composition, the former of which is due to the action of the hydrogen sulphide present in the coke-oven gas, and a method of eliminating it has been worked out which consists in treating the coke-oven gas with a large excess of sulphur-dioxide solution on the counter-current system, the excess of dioxide being removed by subsequent scrubbing with water and used over again. That pure alcohol can be made from coke-oven gas is certain, but it has yet to be done on a commercial scale. By using purified coke-oven gas and alcohol recovered by distillation under reduced pressure, it should be possible to obtain an 80% conversion of the absorbed ethylene, and by using an acid stronger than 95% it should be possible to obtain a higher ethylene absorption than 70%.

Prior to the meeting, at which over 150 were present, a visit was made to the By-product Works of Messrs. Sadler and Co., Ltd., Middlesbrough.

EDINBURGH AND EAST OF SCOTLAND.

The hon. local secretary's report on the work of the session, which was read at the annual meeting held on March 8, records the holding of six meetings attended by an average of forty members. Twenty new members joined the Section, twelve were lost by deaths and resignations, and ten by transference to other Sections; the total membership to date is 157. The Committee has now lost the able services of the chairman, Dr. D. S. Jerdan, who is leaving to take up an appointment in Brussels, and Dr. A. C. Cumming is also leaving Edinburgh to engage in chemical manufacturing work in Liverpool. The thanks of the Committee are accorded to the Council of the North British Branch of the Pharmaceutical Society, and to its secretary, Mr. J. Rutherford Hill, for allowing the Section to use the Society's hall for its meetings.

BIRMINGHAM.

A paper on "Colour in Water: Its Nature and Removal" was read by Mr. Joseph Race at a meeting held on March 10 at Birmingham University. The paper was confined to a consideration of brown peaty waters which are found in various countries. The properties of these waters were fully described, and a *résumé* was given of the evidence of the colloidal nature of the colouring matter, together with details of experiments illustrating the practical importance of the behaviour of the colloids on the addition of an electrolyte, such as alum. It was stated that the effect of alum on coloured waters had been intensively studied in America, because the colour in many waters in that country is often very high and the water consumption is four to five times that in England. The effect of these causes on filter design was indicated. The study of alum flocculation has led to the adoption of the "excess alum" method, and this has resulted in considerable economies being effected at many plants.

Removal of colour by electrolytic methods was also discussed and a detailed description was given of an experimental plant in which aluminium electrodes were employed. The results showed that when precipitation is effected in this manner the amount of aluminium consumed is very much less than when alum is used; also that the alkalinity, and consequently the carbonic acid content, remain unchanged. The costs, calculated on a run of 20,000 gallons, were given, together with analyses of the various precipitates obtained with both aluminium and iron electrodes.

An informal dinner for members of the Section —the first since 1913—was held in the White Horse Hotel on March 14, and was attended by about 30 members.

MANCHESTER.

The annual supper of the Section was held on March 10 in the Albion Hotel, Manchester. Mr. John Allen presided, and about 130 members and friends were present. On the announcement of the death of Lord Moulton all present rose in silence to express their regret. An informal musical programme occupied a portion of the evening.

MEETINGS OF OTHER SOCIETIES.

INSTITUTE OF METALS.

The Spring Meeting of the Institute of Metals, held at the Institution of Mechanical Engineers on March 9 and 10, was presided over by Sir George Goodwin and was well attended. The subject of season-cracking in brass was brought forward in a paper by Messrs. H. Moore, S. Beckinsale and Miss Mallinson, who produced evidence, from the examination of a very large number of cold-worked articles at Woolwich, in favour of the view that the cracking is caused by chemical corrosion, especially by traces of ammonia, acting selectively on the intercrystalline material. The presence of initial stress is essential to the development of season-cracks, and the composition of the alloy is of secondary importance. The discussion showed that cracking may sometimes occur in new rods, especially in winter, under conditions which seem to exclude the possibility of corrosion, and it was also pointed out that the phenomena of fire-cracking and season-cracking are essentially similar, although the former are almost certainly not of chemical origin. Fortunately, the liability to crack is removed by low-temperature annealing, which is without any softening effect on the metal. As is usual when this subject arises, a part of the discussion resolved itself into a duel between the defenders and the opponents of the hypothesis of an amorphous intercrystalline cement. The whole subject is to be considered at the forthcoming joint meeting arranged by the Faraday Society. The same authors also dealt with another form of intercrystalline brittleness, produced in copper by the action of reducing gases. This action is due entirely to the presence of cuprous oxide, and copper which has been thoroughly deoxidised is immune. The addition of a small quantity of zinc is particularly recommended for this purpose, and attention is called to the useful properties of an alloy of copper containing from 2·5 to 3% of zinc, which works well hot or cold, and will stand severe deformation. It casts well, and is not subject to season-cracking.

Prof. C. A. Edwards and Mr. A. M. Herbert described measurements of the dynamic hardness of copper-zinc and copper-aluminium alloys at high temperatures, showing that critical temperatures in such alloys are more readily revealed by dynamic testing than by the slow application of a tensile stress. An interesting point mentioned in the discussion was that workmen when heating billets of such alloys determine their approximate temperature by poking with a pointed rod, a rough application of a dynamic hardness test. Mr. P. H. Brace, of Pittsburgh, communicated an account of the metallurgy of calcium, describing the modern form of electrolytic cell, using pure calcium chloride as the electrolyte, and tabulating the principal properties of the metal. It is possible that calcium may find more extended uses in metallurgy. In the absence of Prof. H. C. H. Carpenter, through illness, the further paper on the recrystallisation and crystal growth in metals, in collaboration with Miss C. F. Elam, was read by the latter. The new results deal mainly with aluminium, and it is shown that the complete destruction of the crystal structure, often described by previous workers as resulting from severe cold-working, does not take place, and that the confused micro-structures so often recorded are due merely to the difficulties of etching this material. The birth of new crystals in the metal during annealing is clearly shown, and a comparison with brass and with aluminium-zinc alloys proves that the new crystals arise in the boundaries of the old. The remaining paper, by Dr. J. L. Haughton, continued his earlier work on the revision of the copper-tin system, and included a diagram covering the range from 35 to 100 per cent. of tin. Even now, some of the transformations are difficult to understand, and the author's careful determinations of electrical resistance at varying temperatures indicate changes of which there is at present no explanation.

THE CHEMICAL SOCIETY.

The Annual General Meeting was held at Burlington House on March 17, when the following elections were announced by Sir J. J. Dobbie:—*President:* Sir James Walker; *Vice-Presidents:* Prof. H. E. Armstrong, Sir J. J. Dobbie, Prof. W. H. Perkin, Sir W. J. Pope, Dr. A. Scott, Sir W. Tilden, Prof. F. G. Hopkins, F. S. Kipping and J. F. Thorpe. *Ordinary Members of Council:* Prof. J. S. S. Brame, C. H. Desch, T. S. Patterson, Drs. T. Slater Price, R. Robinson, N. V. Sidgwick, and Messrs. E. V. Evans, H. B. Hartley, and W. Rintoul. The Longstaff Medal was presented to Prof. J. F. Thorpe, and Sir J. J. Dobbie read in abstract his presidential address on the value of the study of the history of chemistry.

In the evening the Anniversary Dinner was held at the Hotel Cecil, Strand, W.C. 2. Among the guests were the Right Hon. Sir Alfred Mond, the Right Hon. Lord Bledisloe, Prof. C. Moureu (vice-president of the Société Chimique de France), Sir J. Dewar, Sir W. Tilden, Prof. C. S. Sherrington, and the Hon. Mr. Justice Sargant. The number present was 224.

After the loyal toasts Sir Alfred Mond, in proposing the Chemical Society, referred to its distinguished past presidents, and expressed the fear that the spirit which drove Hofmann from England and which helped to drive the dye industry to Germany was not yet extinct. "Science and research are not the fads of the few or the follies of the aged, but vital necessities to the existence of the nation." The exhaustion which followed the Napoleonic wars was greater than that which existed today, and the key to recovery lay in some great improvement in our methods of production, some great discovery as fundamental and far-reaching as that of the steam engine in its epoch.

Sir J. J. Dobbie, in reply, outlined the more important changes and developments which had occurred in the Society during the past two years. In particular, he emphasised the reformation of the charter on a more democratic basis, the admission of women to the fellowship, and the financial stringency. The number of fellows had increased from 3205 in 1914 to 3569 in 1919, and last year there were 3721; but more important than this growth in membership was the recent increase in the number of papers printed in the Transactions; from 272 papers in 1914 the number had fallen to 89 in 1918, but last year it rose to 182. The insufficient accommodation afforded by the Society's rooms in Burlington House was then referred to, and the hope expressed that means would be found to realise the aspirations of chemists as embodied in the proposals of the Federal Council for Pure and Applied Chemistry.

The toast of the Past-presidents, coupled with the names of Sir James Dewar, Sir Edward Thorpe, and Sir William Tilden, was given by Prof. H. B. Dixon, who outlined in brief but witty terms the outstanding achievements of these three guests of honour, and in their acknowledgments, Sir J. Dewar and Sir W. Tilden gave interesting reminiscences of their early associations with some of the chemical pioneers of the last century. Sir E. Thorpe was, unfortunately, absent owing to illness.

Prof. F. G. Donnan gave the toast of the Guests, which was replied to by Prof. Moureu, the Hon. Mr. Justice Sargant, and Prof. C. S. Sherrington.

THE OPTICAL SOCIETY.

At a meeting of the Optical Society held at the Imperial College on March 10, Mr. T. F. Connolly described and exhibited "A Handy Form of Measuring Microscope." The instrument comprises a microscope system of relatively low power; a double image prism traverses the object space, and is controlled by the rotation of a milled band operating a spiral slot. Exit pupil discs of telescopes or other optical instruments and Brinell impressions can be measured by a single contact setting of the edges of the duplicated discs. The range in the experimental instrument is from 1 to 6 mm., and the accuracy when used with a fixed focus for Brinell impressions is about $\pm 0{\cdot}02$mm. The reading scale is very open and is divided to 0·1 mm. No vernier is used.

PERSONALIA.

Dr. F. H. Hatch has been appointed adviser to the Mines Department on questions relating to the metalliferous mining industry.

The Albert Medal of the Royal Society of Arts for 1920 has been presented to Prof. A. A. Michelson, professor of physics in the University of Chicago.

Dr. F. C. Thompson, Sorby Research Fellow in the University of Sheffield, has been appointed to the chair of metallurgy in the University of Manchester.

Prof. J. S. S. Brame, professor of chemistry in the Royal Naval College, Greenwich, has been elected president of the Institution of Petroleum Technologists for 1921-22.

Sir Edward Thorpe (Great Britain), Prof. Le Chatelier (France), Prof. Ciamician (Italy), and Dr. Ernest Solvay (Belgium) have been elected honorary foreign members of the Chemists' Club, New York.

The principalship of the Manchester Municipal College of Technology has been filled by the appointment of Prof. B. Mouat Jones, who has been professor of chemistry in the University of Aberystwith since 1919.

NEWS AND NOTES.

JAPAN.

The Wood-Distillation Industry.—The wood-distillation industry in Japan originated during the war, when the rubber planters in the East were entirely cut off from the German sources of supply of acetic acid, and Japan was called upon to meet their entire requirements. The consumption of calcium acetate in Japan has been large but variable during the last eight years; in 1913 it was 4049 long tons, in 1916, 577 t., and in 1919, 5398 t. Imports, formerly derived mainly from England and the United States, have since 1916 come from the latter country only. The demand for acetone is estimated at 600—700 tons per annum, and the country can now supply its own requirements. Much progress was made in the production of methyl alcohol until 1917; but since that year it has diminished considerably, partly owing to increased importation from America. The chief product exported is acetic acid, which goes to the Straits Settlements, British India, and the Dutch East Indies. Exports of this acid were 669 t. in 1915, 2470·6 t. in 1917, 2137·8 t. in 1919, and 890 t. during the first four months of 1920. The export trade diminished in 1920.—(*Chem. Ind., Dec.* 29, 1920.)

Menthol and Peppermint Oil in Japan.—Menthol is obtained as a residue in the refining of the oil distilled from a variety of peppermint grown in the Okayama and Hiroshima prefectures, in Yamagata, and in Hokkaido (the chief source). The crystals are exported mainly to America and the peppermint oil to England (formerly Germany). The total production, average prices, and exports during the period 1909—1920 were as follows:—

	Menthol.			Peppermint Oil.		
	Production.	Average price.	Total exports.	Production.	Average price	Exports from Yokohama.
	Long tons.	Sh. per lb.	Long tons.	Long tons.	Sh. per lb.	Long tons.

—(*U.S. Com. Rep., Feb.* 3, 1921.)

UNITED STATES.

Magnesium in 1919.—A report of the United States Geological Survey, issued in 1920, states that 127,465 lb. of metallic magnesium, valued at $247,302, was made by three companies in 1919, a decrease of 55 per cent. in quantity and 60 per cent in value compared with 1918. The decrease was due to the cessation of the demand for war purposes and to lack of foreign orders. Most of the magnesium marketed was in stick form, but over one-tenth of the output was sold as powder. Average prices were $1.83 per lb. for stick magnesium and $2.85 for the powdered metal. Magnesium is prepared from anhydrous sodium-magnesium chloride, left after the extraction of salt from brines at Midland, Mich., and Pomeroy, Ohio; from magnesium chloride from the waters of the Great Salt Lake, Utah, and from sea water at San Francisco Bay; from Californian magnesite; and from precipitated magnesium carbonate. Metallic megnesium is mainly used as a deoxidising agent in metallurgy, but its use as a constituent of alloys is increasing and may eventually become the more important.

Abrasive Materials in 1918.—According to "Mineral Resources of the United States" (1918, Pt. II., pp. 1171–87), the total value of all abrasive materials, exclusive of felspar and quartz, consumed in the United States in 1918 was $10,991,964, of which about 26 per cent. represented natural abrasives. Imported abrasives were valued at $1,187,632. The production of grindstones and pulpstones, garnet, pumice, and grinding pebbles increased, and that of emery, corundum, diatomaceous earth and tripoli, and tube-mill lining decreased. American millstones are still mainly made of quartz sandstones and conglomerates, but some are made of granite; the production in 1918 was greater than it had been for about 30 years. Pulpstones are heavy grindstones used for grinding wood in the manufacture of pulp and paper; the increased production of 26 per cent. compared with that in 1917, and of 320 per cent. over that for 1915, was probably due to the difficulty and high cost of importing stones from Great Britain.

North Carolina is the sole producer of corundum; the output in 1918 was about 10,000 short tons, or 38 per cent. less than in 1917. Of diatomaceous earth, 2965 short tons was sold, but there was also a considerable production for special uses which the Geological Survey is not at liberty to report. Owing to the embargo placed upon all overseas imports of pumice, domestic supplies were developed and these proved quite satisfactory except for the finest work, viz., lithography and metal-polishing prior to plating; the production was 30,637 short tons. Similarly, the cutting off of supplies of "flint liners" for tube-mills (blocks cut from flint or other hard silicious rock) developed a domestic supply which proved quite satisfactory.

Three different kinds of artificial abrasives are manufactured in the United States:—(1) Metallic abrasives, including "diamond crushed steel" (crushed crucible steel), "angular grit" (crushed chilled iron), and "crushed cast iron" all made by the Pittsburg Crushed Steel Co.; (2) silicon carbides, including carborundum, crystolon, and carbolon; (3) aluminium oxides, including alundum, aloxite, etc. In 1917 the production of artificial abrasives amounted to 57,911 short tons, valued at $8,137,242; the production figures for 1918 are incomplete.

Peat in 1919.—The quantity of peat, excluding raw and including air-dried and mechanically-dried peat, produced in the United States in 1919 was 69,197 short tons, valued at $705,532, an average price of $10.20 per ton. This represents a decrease of 35 per cent. in quantity compared with the 1918 production. Most of the output was used for fertiliser purposes, either directly or as a nitrogenous ingredient of compound fertilisers; 6402 t. of carbonised peat was used as a constituent of cattle foods and a small amount as fuel.—(U.S. *Geol. Surv., Oct.* 14, 1920.)

SOUTH AFRICA.

Coal By-Products.—According to the General Manager of Railways, considerable attention is being given by the collieries to the recovery of coal by-products. There are large accumulations of waste and low-grade coal at the various collieries which, though not suitable for sale purposes, can be treated for by-products. The utilisation of this waste material has received greater attention during recent years, and it is said that the percentage of waste has been halved since 1910. Even to-day the waste coal is estimated at 1 million tons per annum. Much experimental work has been done recently on the testing of coal for the production of coke and tar and the distillation of oils and creosote. The companies are hopeful of the outcome of these by-product industries, and there is

certainly a large field for development. The building up of a trade in coal by-products, which can be used in such a variety of ways, would be of inestimable value to the Union and would no doubt result in the creation of a number of new industries.

Mineral Production in 1920.—The Imperial Mineral Resources Bureau has received from the Department of Mines and Industries of South Africa the following statistics relating to the production of minerals and metals in 1920:—

	Weight. Fine oz.	Value. £
Gold (output)	8,158,455	34 654 922
Silver (sales and shipments)	892 205	224,769
	Carats.	
Diamonds (output)	2,551,665	14,762,956
	Tons.	
Coal (total coal sold)	11,473,452	4,506,572
Copper ore and concentrates (sales and shipments)	10,874	445,007
Tin concentrates and metallic (sales and shipments)	2,451	446,284
Other base minerals (output) ..	—	153,694
Total value ..		55,194,204

* Value calculated at the standard rate of £4·24773 per fine ounce.

CANADA.

Projected New Sodium Carbonate Plant.—The Soda Mining and Products Company is to erect a new evaporating plant at Soda Lake in British Columbia. Soda Lake is situated 3700 feet above sea level, is 100 acres in extent, and its waters contain 6 per cent. of sodium carbonate.

Mineral Production in 1920.—The Chief of the Division of Mineral Resources and Statistics for Canada states that, viewed as a whole, the mineral industry was prosperous in 1920, although in Central Canada the fuel supply was inadequate and transport facilities insufficient; and in many camps labour was scarce and expensive. The production of copper, nickel, zinc, coal, etc., quickly recovered from the depression of 1919, but the present trade slump began too late in 1920 to have much effect on the mineral production of that year. Canadian mineral production has risen in value from $176,686,390 in 1919 to roughly $200,000,000, thereby closely approaching that for the maximum year, viz., $211,301,897 in 1918.

With an output of 27,455 long tons, nickel production showed an increase of 38 per cent. over that in 1919; the annual production of this metal for some years hence will be limited only by the demands of the market, as reserves are ample and the smelting capacity is in excess even of the highest war-time production (41,295 t. in 1918). There was an increase of 10 per cent. in the production of copper (36,830 t.), but the output of lead, including lead ingots and lead recovered from ores exported decreased to 19,565 t. British Columbia produced 13,524·5 long tons of refined zinc out of an estimated total of 18,750 tons (14,373 t. in 1919). The value of the gold output is estimated at $16,000,000 ($15,850,423 in 1918), over two-thirds of which was produced in Ontario. There was a general reduction in the output of silver; British Columbia produced 13,500,000 oz. compared with 16,020,000 oz. in 1919. Shipments of asbestos in 1919 included 136,765 t. of fibre and 22,471 t. of powder, a production which, it is estimated, was exceeded by 25 per cent. in 1920. The estimated output of coal, 16,000,000 short tons, was about 18 per cent. greater than in 1919, but the production of iron ore did not exceed 120,000 short tons, compared with 197,170 short tons in the previous year. There were larger outputs of pig iron and steel, the production in 1919 and 1920 being:—Pig iron, 917,781 and 1,080,000 short tons; steel ingots and steel castings, 1,030,342 and 1,220,000 short tons. (*Bd. of Trade J.*, *Feb.* 17, 1921.)

AUSTRALIA.

Mineral Production in 1920.—The following table, showing the mineral production of Australia in 1920, has been compiled by the Imperial Mineral Resources Bureau:—

	Production. Long tons.	Exports. Long tons.
Copper—		
Bar copper..	24,069	28,612
In blister copper	2,000	2,000
In copper ore	115	115
Lead	4,077	50,069
In lead bullion	1,939	1,798
In concentrates	4,122	4,122
Zinc	9,665	5,689
Zinc concentrates	—	52,732
Tin	4,108	3,015
Pig iron	344,000	22,657
Arsenic..	1,202	582
	oz.	oz.
Silver	701,177	341,001

The zinc concentrates contained approximately 11 oz. silver per ton, 47 per cent. zinc, and 7 per cent. lead.

Glassware Manufacture.—The annual imports of glassware into Australia are so great as to indicate that locally manufactured supplies fall far short of the demand. In view of the absence of any domestic glassware manufactory in Western Australia, the discovery at Wanneroo, near Perth, of a particularly high grade of glass-making sand is considered an excellent opportunity for establishing a useful secondary industry. Reports of the test of a bulk sample of the sand carried out in a well-known works in New South Wales fully confirm the opinion of the Government Mineralogist, Dr. G. S. Simpson, whose analysis gave:—Ignition loss, 0·08%; on ignited sand Fe_2O_3 0·4%, CaO nil, Al_2O_3 nil, TiO_2 0·007%, and SiO_2 99·81%. Colour of ignited sand, white.

The owners of the mineral claim have decided to form a company to work the deposit, and it is intended to secure the most expert advice that can be obtained. The raw material is so abundant and the quality so good that success seems assured. Western Australia is so situated that there is a big market in the Dutch East Indies and the Federated Malay States for goods of the description that it is proposed to manufacture, and there is every reason to believe that a good foreign market can be establised, apart altogether from the home demand.—(*Ind. Austral.*, *Dec.* 9, 1920.)

BRITISH INDIA.

Chemical Industries in Western India.—The annual report of the Director of Industries of the Bombay Presidency for 1919-20 states that Dr. A. N. Meldrum and Mr. D. M. Gangolli have written the first bulletin of the Department on the preparation of sulphuric casein. A large amount of casein is produced in the Bombay Presidency, but it is very crude, and the authors are working to produce a high-grade product. The hand-made paper industry at Ahmedabad has been studied by Dr. Meldrum and Mr. Bharucha, and efforts have been made to popularise the unglazed paper for filter work and as an absorbent for drying plants. The investigation of the Kharaghoda bitterns has been continued and a promising sample of Epsom salts has been obtained by Mr. A. J. Turner, who has also examined the economic production of refined salt from ordinary salt crystals. Favourable results were obtained, and a plant will, it is hoped, shortly begin working. The extraction of bromine from the bitterns at Kharaghoda and Aden has been investigated, but appears economically unpromising under present circumstances. The wood-distillation industry has been closely investigated and the conclusion was reached that it was inadvisable to erect a fully-equipped plant, as the demand for by-

products had decreased. The demand for charcoal, however, is rapidly growing, and a plant producing charcoal of good quality, together with one or two by-products for which there is a market, would have a chance of success. Possible developments of hydro-electric power in the Presidency are being examined, as the price of Indian coal, like that of oil fuel, is increasing and supplies and labour are difficult to obtain. Power alcohol has also been considered, and a plant for producing a mixture of alcohol and ether is being completed in Hyderabad State, but development is hindered by the circumstance that any scheme to distil alcohol on a large scale in India would have to reckon with the competition of cheap alcohol imported from Java.—(*Indian Tr. J., Jan.* 21, 1921.)

GENERAL.

Sugar Beet in England.—It now appears certain that the beet-sugar factory of Home-Grown Sugar, Ltd., the company in which the Ministry of Agriculture holds half the share capital, will be ready by next autumn; much of the plant ordered from France has already arrived. Supplies of sugar beet for the present year have been contracted for, and although the factory will be able to deal with 600 tons of beet per day for 100 days, the tonnage for the first year is to be limited to 20,000, grown on 2365 acres, in order not to overload the factory, while the machinery is new, and to allow the staff to be adequately trained by the French specialists engaged. There are 425 farmers in Nottinghamshire and Lincolnshire who are cultivating an average of 5½ acres each, and it would have been possible to have doubled the acreage actually contracted for. For the reasons stated above, only 200 of the 400 acres originally contemplated are being grown on the Kilham Estate. The price payable per ton of beet delivered at the factory has been fixed at £4, equivalent to £3 17s. 6d. delivered on rail, and as experimental trials showed that the cost per acre of 12 tons (with an average sugar content of 20 per cent.) delivered on rail was £29 3s. 4d., there should be sufficient margin to induce the farmers not to limit expenditure on fertilisers, cultivation, and supervision, all factors that materially affect sugar content as well as yield.—(*Official.*)

Asbestos, 1913—1919 (H.M. Stationery Office, 34 pp., 1s.) is one of the most interesting pamphlets yet issued by the Imperial Mineral Resources Bureau. The name " asbestos " is applied to several fibrous silicate minerals differing from one another in chemical composition and physical properties. The principal asbestos mineral used in commerce is *chrysotile*, or serpentine asbestos, which is essentially a hydrated silicate of magnesium. It has great tensile strength and flexibility, is unattacked by acids, and is remarkably fire-resisting, although at 500° C. it becomes dehydrated and loses its tensile strength. It is a good insulator for both heat and electricity and is well adapted for spinning. *Crocidolite*, or blue asbestos, is a silicate of iron and sodium and is found in large quantities only in South Africa. It has great heat-insulating capacity, but its fire-resisting properties are poorer than those of chrysotile owing to its comparatively low fusibility. Asbestos cloth, rope, felt, etc., can be manufactured from crocidolite fibre, as also can sheets, tiles, cement, and other building material.

The commercial value of asbestos depends chiefly on tensile strength, flexibility, length and fineness of fibre, dehydrating temperature, and temperature of fusion, but other factors of importance are heat-insulating capacity, electrical insulating power, and colour. For spinning and weaving into fabrics, ropes, and engine packing, the qualities of first importance are tensile strength, fire resistance, and length of fibre. Although of greater monetary value, such articles form only a small proportion of the total output of asbestos manufactures. The larger proportion of the asbestos mined is used for sheets, tiles, slabs, millboard, joint-packing, etc. in the building, engineering, and electrical industries. Finely ground *anthophyllite* (silicate of magnesium and iron), low-grade *tremolite* (silicate of magnesium and calcium), and the residues from the chrysotile mills are used extensively in the manufacture of asbestos cements, fireproof bricks, tiles and other roofing material, paints, etc. Asbestos wool mixed with a solution of sodium silicate makes a fireproof cement of great strength.

The largest and most valuable deposits of asbestos occur within the British Empire. Canada has long been the chief producer of chrysotile asbestos (137,000 tons in 1919, or about 80 per cent. of the world's output). Rhodesia is second with about 8700 tons, but, arising out of the keen demand for Rhodesian fibre, a policy of rapid and extensive development is being pursued in that country. The Union of South Africa, which is the only producer of crocidolite, exported 3500 tons in 1919. Russia was formerly an important producer (17,200 in 1913), and other producing countries, in order of importance, are Australia, Cyprus, United States, India, and Italy. The price of Canadian No. 1 is stated to have risen from \$300—\$350 in 1913 to \$2500—\$3000 per ton in 1919. Cheaper grades range down to \$25—\$30 for "C short fibre." Most of the Rhodesian and South African asbestos is exported to Great Britain, but the Canadian output is exported largely to the United States, only relatively small quantities being sent to the United Kingdom.

The International Chemical Union.—The full report of the meeting which was held in Rome in June last has now been published from the offices of the secretariat at 46, Rue des Mathurins, Paris. (*Cf.* J., 1920, July 31, 251 R.)

Importation of Dyes and Dye-Intermediates.—The list of products covered by the Dyestuffs (Import Regulation) Act, which has been drawn up in consultation with the Dyestuffs Advisory Licensing Committee, is now available and may be obtained on application either to the Board of Trade, Industries and Manufactures Department, Great George Street, Westminster, London, S.W. 1, or to the Dyestuffs Advisory Licensing Committee, Board of Trade, Danlee Buildings, 63, Spring Gardens, Manchester.

Chemical Industry in Belgium.—The shortage of fuel and raw materials has prevented the Belgian chemical industry from recovering its pre-war position, but exports have been increasing. Supplies of sulphuric acid are very short, the production in the Gand district being at the rate of 40,000 tons per annum, compared with the pre-war output of 125,000 t., and owing to the strike the Vieille Montagne works are producing at only 40 per cent. of their capacity. The oil industry is in a difficult position on account of the high prices and shortage of raw materials, and the rubber industry is similarly situated. Full time, however, is being worked in the artificial silk industry, and export orders have been plentiful.—(*L'Ind. Chim., Dec.*, 1920.)

The Belgian Iron and Steel Industry.—In spite of the active reconstruction work carried on since the armistice, the Belgian iron and steel industry is still far from attaining its pre-war position, mainly because a large proportion of the labour has had to be diverted from production to repair work. Out of 51 blast furnaces, 21 are producing at the rate of 65 per cent. of the total 1913 production and 7 are ready for blowing in. There is sufficient coke for present needs, but gas coal for generators and Martin converters is in short supply. By the autumn of 1920 the iron and steel industry was producing 51 per cent. of its pre-war output of pig-

iron, 69 per cent. of finished iron, 54 per cent. of steel ingots, and 62 per cent. of finished steel. Since May, 1920, the high prices have led to a reduced demand, and French, Belgian, and Luxemburg producers have had to agree to fix the price of pig iron at 500 fr. per ton. Further, the re-adjustment of labour costs to falling prices is a difficult problem, and, in spite of the progress made in reconstruction, the present market outlook provides no incentive for further expansion (*cf.* J., 1921, 15 R).—(*U.S. Com. Rep., Feb.* 7, 1921.)

The Belgian Glass Industry.—The Belgian glass industry, and in particular the plate-glass industry, profited by exceptionally favourable conditions during the early months of 1920, but now there is a general lack of new business and plate-glass manufacturers are curtailing production in order to maintain prices; the production of plate glass in the first eight months of 1920 was 98·5 per cent. of that in the same period of 1913. Window-glass manufacture is also seriously affected by the decline in demand, and prices have dropped by nearly 50 per cent. The problem of diminishing production costs by reducing labour charges has become so acute that arrangements are being made to introduce a process for drawing glass mechanically. The flint-glass industry has been less affected by the prevailing depression. There are at present 35 plants producing table-ware, and some of them, especially the Cristalleries Val St. Lambert, manufacture the highest and most artistic grades of cut-glass. Cut-glass and table-ware are exported to the United States to the value of about 500,000 fr. monthly. Much of the effectiveness of Belgian flint glass depends on the skill of the workmen, machinery being but little employed. The wages of glass workers and cutters vary from 25—30 fr. and 35—40 fr. a day, according to the district; increases have been at the rate of 320 and 400 per cent., compared with an increase of 370 per cent. in the cost of living since 1914. The exports of glass (in metric tons) during the first 8 months of 1920 were: Rough plate, 662; polished plate, 22.463; window glass, 120,466; common glass, 67; table-ware and cut glass, 15,225; bottles, demijohns, etc., 10,810. There has been an enormous increase in exports to the United States during the past year, viz., 3599 t. in the first ten months, compared with 162 t. in the same period of 1919.—(*U.S. Com. Rep., Jan.* 21, 1921.)

The Window-Glass Industry in Sweden.—Competition from Belgium has very seriously affected the Swedish window-glass industry; only three or four factories are now working. It is reported that Belgian firms are dumping window-glass on the Swedish market at prices below the cost of production, and that the industry has applied to the Government for higher tariffs and temporary import prohibition. During the period April to July, 1920, 1870 metric tons of window-glass was imported, and the home production was 2130 t.—(*U.S. Com. Rep., Feb.* 3, 1921.)

The German Fluorspar Industry.—The largest fluorspar deposits in Germany are situated in the Hartz district, Upper Palatinate, the Thuringian Forest, and the Black Forest; that found in the Upper Palatinate contains 95—98 per cent. of calcium fluoride and relatively little silica. The quantities supplied to the various consuming industries before the war were distributed as follows:—Iron and metal smelting, 79—84%; glass industry, 10—15%; chemical, enamel, and optical industries, 5% each. The use of fluorspar in the iron industry has increased since the armistice, as it effects an economy in fuel. Owing to the depreciated currency, German producers are able to sell fluorspar for exportation at lower prices than any of their foreign competitors.—(*U.S. Com. Rep., Feb.* 9, 1921.)

Carbon Dioxide as Fertiliser.—The possibility of manuring plants with furnace gases containing carbon dioxide by Dr. Riedel's method appears to be established, as his results have been confirmed by independent researches and trials by Bornemann and Reinau. Dr. Claassen, however, criticises the practicability of the method and its economy when used on a large scale. The plant for distributing the gases is inexpensive; all that is required is the main pipe and smaller pipes for conducting the gases to the different parts of the fields. Then by opening or closing the valves, the farmer can treat his plants with larger or smaller amounts of carbon dioxide according to the weather and the state of the plants. From the results it appears that lupins after treatment with gas gave, in the dry state, a yield 2·9 times greater than an untreated crop. A sugar-beet crop was increased by 85 per cent., with 1½ per cent. more sugar.—(*Chem.-Z., Feb.* 15, 1921.)

The Potash Industry in Germany.—A resolution to increase the inland prices of potash compounds by 50—55 per cent. was considered by the Potash Council (Reichskalirat) on February 1, but not carried as the voting for and against was equal. The representatives of agriculture and labour voted against the resolution. The case for increasing the prices included the following considerations. In spite of enormously increased costs of production, potash prices have not been raised since December, 1919. Whereas the price of potash has only risen five to sixfold since 1913, that of nitrogen has risen 9 times, phosphoric acid 19—20 times, and agricultural produce 10¼ times. Costs in the potash industry have increased since 1913 as follows:—Lignite 20 times; coal 13 times; wages 10 times; and costs of materials have risen far more than any of these items. The doubling of the railway freights in March, 1920, hit the industry particularly hard because coal from the Ruhr district being unavailable (under the Spa Agreement), the potash works have to use three times the amount of lignite, and this has to be transported distances up to 250 kilom. About 88 per cent. of the losses on inland sales in 1920 were made good by the export trade, but this was no longer possible in 1921. Employees have been dismissed from 21 of the works, further dismissals are taking place daily, and working hours have been curtailed at 46 works. The Labour Minister has just notified further increases in wages and fuel which, it is estimated, will entail additional charges on the industry of 42 million and 17 million marks, respectively. The Potash Syndicate is anticipating the closing down of many more works.—(*Z. angew. Chem., Feb.* 2, 18, 1921.)

The Balsam-Resin Industry in Germany.—A translation of an article on the German balsam-resin (Balsamharz) industry by Vice-Admiral D. F. Funke (*Handelszeitung, Feb.* 10, 1921) has been made available, together with supplementary information, by the Department of Overseas Trade.

Prior to the war the production of resin was increasing and imports were decreasing. Thus 113,481 tons, of which the United States supplied 78 and France 19 per cent., was imported in 1912, and 96,265 t. (U.S.A. 80, and France 16·5 per cent.) in 1913. The exports were 17,060 t. in 1912, and 25,893 t. in 1913, Austria-Hungary taking 31·4 and 30·5 per cent., and Russia 29·6 and 26·5 per cent., respectively. During the war the industry, controlled by the German Government and under the supervision of technical experts, was developed to a remarkable extent. Government control was abolished at the end of 1919, and the new companies that had been formed to treat the raw material were placed in a very precarious position. However, as a result of the intervention of the German Minister of Economics, an agreement was reached

between the refiners and the consumers, under which a new company, the Deutsche Harz-Gesellschaft, was formed to take over the distribution of all the resin produced. All risks were borne by the consumers, who agreed to order what they required annually at a price to be based on the world's market prices at the time of the order. Resin manufacturers and merchants, however, have met with opposition from the Forest Authorities, who apparently have done all they could to obstruct the industry. Various excuses were made to diminish production, private forests were closed down, and finally a charge of 8 marks per kg. was made for the balsam-resin. Owing to the heavy fall in price in 1920, the demand ceased and representations were again made to the Minister of Economics which resulted in the price being reduced to 6 marks per kg. This did not satisfy the consumers, and efforts were then made to obtain statistics of the cost of production to the forest authorities. No figures were available for 1920, but official figures for 1919 showed that the Prussian forest authorities in 1913 made a profit by selling at 3 marks per kg. Further, the cost of production was so low that with a production of 1307 kg. per hectare (10·4 cwt. per acre) a profit of 2·57 marks per kg. was made. During the war the forests in the Oberost district actually produced 1500—2000 kg. per hectare, and these figures are now being put forward to prove that the forest authorities are over-charging.

The Beet-Sugar Industry in 1920.—In an article on the progress achieved in various branches of the beet-sugar industry during 1920 (Chem.-Z., Feb. 22, 1921), Prof. E. O. von Lippmann insists that this industry should be thoroughly re-organised. The American statement that single-germ seeds show increased resistance to animal and vegetable pests is not corroborated; opinions, in fact, differ as to the desirability of growing these single-germ seeds at all. Concentrating syrups on an extensive scale by means of low temperatures is, according to Pokorny, Linsbauer and others, impracticable both from the technical and economic standpoints. Stenzel's process for fermenting waste waters by means of yeast, with the object of manufacturing food-material, does not offer any prospect of success. Opinion is unanimous in Germany, France, Bohemia and other countries that the usual chemical control in beet-sugar factories is inadequate. Teyssier calls attention to the inaccuracy in calculating the "rendement," or net sugar, of samples of raw sugar from ash determinations. British, American and most French sugar chemists have declared themselves in favour of adopting 20 grams as the new normal weight. Zeller, in his exhaustive treatise on the relation between cane and beet sugar, comes to the conclusion that the world's sugar requirements cannot be satisfied by cane sugar alone since its supply is limited by technical, industrial and economic considerations. According to Bartens, the world shortage on September 1, 1920, amounted to 6 million tons, and in his opinion only the re-establishment of the beet-sugar industry can relieve the situation. The conditions in Czecho-Slovakia are the most promising. In Russia and Russian Poland all progress is checked for many years to come. In France also it will take years before the efforts now being made to re-organise the industry can materialise. In Germany, owing to all the reserve stocks having been exhausted by September 1, 1920, the price of refined sugar ultimately rose to 40 marks per kg. Moreover, according to a U.S. Consular Report of February 4, 1921, the total sugar production for the year 1919–20 was only 733,000 t., as compared with 1,346,000 t. in the previous year. To meet her domestic requirements in 1919–20, Germany had actually to import 57,000 t., or more than twice as much as during the preceding year, and a larger importation was only avoided by the existence of reserves from the previous season amounting to 216,000 t. The average yield of 7·5 t. per acre was the lowest for many years. Only 269 beet-sugar factories are now working in Germany.

Emil Fischer Bequest.—The late Prof. Emil Fischer left the sum of 750,000 mk. to the Prussian Academy of Sciences for the establishment of an "Emil Fischer Foundation"; the income from the fund is to be applied to the maintenance of young German chemists studying organic, inorganic, or physical chemistry.—(*Chem.-Z., Jan.* 22, 1921.)

Technical Education in Germany.—The number of students attending the Technical "Hochschulen" in Germany, including 1200 at the Köthen Polytechnic, is 21,000, compared with 18,900 in the winter semester of 1920–21, and 12,200 before the war. In electrotechnology the number of students has increased from 1300 to 3229; in mechanical engineering from 3100 to 6540; in chemistry, natural science, and pharmacy from 1544 to 3174; and in mining and metallurgy from 576 to 785. There are 3209 students at Charlottenburg, 2923 at Munich, 2591 at Hanover, 2264 at Dresden, 2206 at Darmstadt, 1631 at Stuttgart, 1491 at Karlsruhe, 1088 at Aachen, 872 at Brunswick, 837 at Breslau, and 779 at Dantzig.—(*Chem.-Z., Jan.* 22, 1921.)

New Carbide Factory in Hungary.—The first carbide factory to be established in Hungary has been erected at Felsögalla by the Ungarische Allgemeine Kohlenbergbau A.-G. and is now ready to start; it will have an initial output capacity of 80 waggon loads per annum, and will utilise charcoal as coke is in short supply. The chief consumers of carbide in Hungary include the State railways, mining enterprises, the oxygen industry, etc., and it is hoped that a large part of the country's needs in carbide will now be covered.—(*Handelsmuseum, Feb.* 10, 1921.)

Sicilian Phosphate Deposit.—A deposit of phosphate, extending over 10 kilometres, occurs on the shore at Donna Lucata, south of Scicli (Syracuse). The phosphates, present in the form of nodules of varying size, contain an average of 33 per cent. tricalcium phosphate (hand-picked specimens), and the reserve of utilisable mineral is stated to amount to 2 million metric tons.—(*G. Chim. Ind. ed. App., Feb.*, 1920.)

Graphite Production in Madagascar.—The French Colonial Ministry reports that trade conditions were so unfavourable during 1920 that no new graphite deposits were opened up, that operations at some of the old deposits were abandoned, and that the mineral has recently been sold at a loss. The export of graphite has declined from 27,838 metric tons in 1917, to 15,015 t. in 1918, and 4056 t. in 1919.—(*U.S. Com. Rep., Feb.* 5, 1921.)

Tung Oil in China.—Tung oil, or Chinese wood oil, is obtained from the nut of certain species of *Aleurites* which grow luxuriantly in hilly districts and seem to thrive in poor soil. The oil is usually extracted in the interior and shipped to Hankow, where it is stored. Its high price often leads to adulteration, soya bean, groundnut, sesame and cottonseed oils being used for this purpose. The exports from China from 1913 to 1919 were as follows:—1913, 37,598 tons; 1914, 26,164 t.; 1915, 18,473 t.; 1916, 30,665 t.; 1917, 23,890 t.; 1918, 29,098 t.; 1919, 36,515 t. There is room for considerable improvement in the methods of cultivation, harvesting and expressing, and the installation of modern machinery would, it is stated, increase the production by at least 10 per cent. Attempts to cultivate the tung tree in the United States are said to have been successful.—(*U.S. Com. Rep., Feb.* 9, 1921.)

CORRESPONDENCE.

A BRITISH CHEMICAL NEWS SERVICE.

Sir,—There is one notable omission from the literary activities proposed by the Federal Council for Pure and Applied Chemistry, recently made public. Sound suggestions are put forward for making scientific information available to chemists, but nothing is said as to one most important aspect of chemical publicity, namely, the means for keeping the lay public fully informed of the activities of chemists and their bearing on public welfare, for the success of both pure and applied chemistry is ultimately dependent upon an active and well-informed public opinion on all that relates thereto.

You, Sir, have already put forward the suggestion some time ago (*cf.* J., 1918, 27 R, 85 R) that the question of publicity should be taken up by technological and scientific societies on this side of the Atlantic, and I feel that the time is now more than overdue for a revision of our present policy of "laisser faire" in this matter. It is well known to chemists how strong a position the American Chemical Society now holds in forming public opinion in the United States, and there are more than sufficient indications in this country that we also need to make use of the medium of publicity for urging necessary reforms in order to ensure that an adequate weight of educated public opinion will be felt whenever chemical matters come up for consideration, whether the objective be peace or war.

The activity of the American Chemical Society in this direction forms so strong a contrast to our neglect that perhaps I may be permitted to quote from a recent issue of the *Journal* of the American Chemical Society:—

"The A.C.S. News Service continues to grow in usefulness. More and more it is finding a definite and accepted place in the newspaper offices of the country and, under the increased appropriation recently granted, it is proposed to extend this work as far as possible into the field of the weekly newspapers, thereby increasing more and more the public understanding of the significance of chemistry to the nation. Much time has been required to get the monthly clip sheet issued by the News Service thoroughly established. The first attempts to include in this clip sheet textually-reproduced sections of the Journal did not yield very great success. This was then modified in form to cover popular treatment of articles appearing each month in the Journal, and the clippings being received show that this feature is now on a thorough basis and is being widely made use of by the press."

[The clip sheet referred to and the weekly bulletins are being sent to 900 of the leading American newspapers.]

To come to definite suggestions, the Chemical Industry Club might form a nucleus for the project, and weekly meetings might be arranged at the Club, at which a number of typed or printed slips could be distributed to the representatives of various papers and news agencies, with a word of explanation as to the possibilities of each article; the journalists could be trusted to make the best use of such free copy once they understood the nature of the work. By degrees the Club might be made a centre for all inquiries of a chemical nature, and with the formation of a definite *liaison* between the press and chemistry the news service would soon attain to very respectable dimensions. Now is the time to make the necessary preparations, and I would suggest that a meeting be called of all those interested in order to discuss ways and means for getting such a British Chemical News Service under way.—I am, Sir, etc., Fredk. A. Mason.

Manchester, March 14, 1921.

PARLIAMENTARY NEWS.

HOUSE OF COMMONS.

Trade in Dyes and Dyestuffs.

In a written answer to Major Barnes, Sir P. Lloyd-Greame stated that the imports into and the exports from the United Kingdom of coal-tar dyes and dyestuffs during 1920 were as follows:—

	Imports.	Exports. U.K. manufactures.	Exports. Foreign and colonial manufactures.
	Tons.	Tonsi	Tons.
Coal-tar intermediates, including aniline oil and salt, and phenylglycine	2,487·5	3,668·4	201·75
Coal-tar dyes:—			
Alizarin	600·4	372·2	1·05
Indigo, synthetic	715·55	690·9	158
Other dyes	8,516·95	5,048·65	195·25

The imports were valued at £8,365,294, the exports of United Kingdom manufactures at £3,258,133, and exports of foreign and colonial manufactures at £305,555.—(Mar. 8.)

Coal Mines (Decontrol) Bill.

This Bill was read a third time on March 18. Its object is to put an end to financial control over the coal-mining industry on March 31, 1921, and to repeal as from April 1, 1921, Section 3 of the Mining Industry Act, 1920, which gives the State power to control prices, export, and wages. Further, it is proposed to divide the period of operation of the Coal Mines (Emergency) Act, 1920, into two periods, in the first of which the owners' profits are to be limited to the pre-war standards, and in the second the owners are to pay the surplus above or receive the deficit below nine-tenths of their pre-war standards, instead of the whole.

Opium.

Mr. Montagu informed Mr. Gilbert that the agreement for the supply by the Government of India to the Government of Hongkong of 10 chests of opium per month at a fixed price had been renewed for a further period of five years as from January 1, 1921.—(Mar. 9.)

Dangerous Drugs.

Mr. Shortt, in reply to Mr. Woolcock, said that he had decided to appoint a small committee to consider and report what further modifications could safely be made in the draft Regulations, having regard to the principle that the use of the drugs under the Dangerous Drugs Act must be safeguarded in the public interest.—(Mar. 9.)

Coal Mining Industry.

Mr. Bridgeman gave the following statistics relating to coal mining in a written answer to Mr. G. Lambert:—

		1913.	1920
		s. d.	s. d.
Cost of raising an average ton of coal:—			
Wages		6 4	29 5¼
Timber and stores		1 10	5 4¾
Other costs			2 3¼
Royalties		0 5½	0 7¾
Total cost		8 7½	34 1¼
Number of persons engaged		1,110,884	1,204,300
Amount of coal raised	tons	287,412,000	229,295,000
Amount of coal raised per person engaged	tons	259	190
Coal exported as cargoes	tons	73,400,118	24,931,853
Coal exported as bunkers	tons	21,031,550	13,840,360

In 1913 the owners' profits were at the rate of 1s. 6d. per ton, and the standard profits payable in 1920 are estimated to be at the rate of 2s. 6½d. per ton.—(Mar. 11.)

Basic Slag Supplies.

Sir R. Sanders informed Mr. A. T. Davies that there was no shortage of basic slag, as the decrease in production within the last two months had coincided with a still greater reduction of demand, and the stocks which had accumulated were twice as large as those held on the same date a year ago. Supplies of phosphatic fertilisers, including superphosphate, basic slag, and ground mineral phosphate for the coming season would probably equal, if not exceed, the supplies in any previous year.—(Mar. 17.)

Anglo-Persian Oil Co.

Mr. Chamberlain informed Col. Wedgwood that the Government holds two-thirds of the ordinary shares and 1000 out of a total of 8,500,000 preference shares in the Anglo-Persian Oil Co.; there was no intention of allowing the voting control over the company to lapse.—(Mar. 14.)

German Reparation (Recovery) Bill.

The German Reparation (Recovery) Bill, which was read a third time on March 18, provides that 50 per cent. of the money due as payment for German goods, or such percentage as the Treasury may prescribe, shall be paid, not to Germany, but to the Treasury through the Customs on account of German reparation. German goods are defined as (a) goods first consigned from Germany, and (b) goods consigned from elsewhere of which less than 25 per cent. of the value is attributable to production outside Germany. Transhipment goods are not affected. The Bill also contains provisions relating to valuation of goods, contracts, etc.

The Prime Minister, in reply to Mr. Pennefather, stated that the Bill would not in any way affect the promised legislation relating to dumping, collapsed exchanges, and key industries.—(Mar. 15.)

OFFICIAL TRADE INTELLIGENCE.

(*From the Board of Trade Journal for March* 10 *and* 17.)

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number:—

Locality of Firm or Agent.	Materials.	Reference Number.
Canada	Tiles	301
"	Pure iron sheets for the manufacture of tanks and roofing ..	329
"	Whitening	335
South Africa ..	Earthenware, china, mirrors ..	304
Belgium	Metals, rubber	309
"	Lubricating oils	310
Bulgaria	Hides, textiles	342
Italy	Oils, fats	349
"	Crude leather	350
.. ..	Machinery for rubber manufacture	351
Latvia	Raw materials for soap making, soda, potash, tallow, coconut oil	313
Poland	Chemicals, raw materials for tanneries, leather	353
Spain	Chemicals, colours, paint, varnish	319
Argentina	Cheap glassware	358
Panama Republic ..	Vegetable oils, paper	361

TARIFF, CUSTOMS, EXCISE.

Argentina.—The export duty on certain hides is suspended until February 2, 1922.

Australia.—Glycerin, crude and refined, for the manufacture of explosives may be imported duty free under the British Preferential Tariff.

Austria.—As from March 1 customs duties when paid in bank notes must be paid at 70 times the rates prescribed by the tariff.

Belgium.—Among the articles under the control of the Ministry of Industry, Labour and Supply that still require export licences are alcohol, matches, butter, lard, fats, malt, yeast, sugar, syrups, and molasses.

Authorisation of this Ministry is still required for the import of butter, malt, sugar, syrup, and molasses.

British India.—The general *ad valorem* duty of 7½ per cent. has been increased to 11 per cent. as from March 1. The customs duty on matches is fixed at 12 annas per gross of boxes, and that on imported liquors has been increased by 3 annas per degree of proof per gallon. The *ad valorem* duty on foreign sugar has been raised to 15 per cent.

Bulgaria.—The surcharge on customs duties when paid in paper currency is now 900 per cent.

Chile.—The increased customs duties take effect as from February 23. Condensed milk, cocoa, sugar, petrol, and oils are exempted from increase.

French Equatorial Africa.—A copy of the Decree establishing new customs regulations may be seen at the Department, 18, Queen Anne's Gate, London, S.W. 1.

Grenada.—The complete text of the revised schedules of Import and Export Duties may be seen at the Department.

Italy.—The stamp tax on perfumery, medicinal specialities, alcoholic beverages, and mineral waters has been doubled.

Kedah.—Export duties have been modified on, *inter alia*, rubber, rambong, damar, wood oil, tin ore, tin, wolfram, hides, bones, bricks, and tiles.

Kenya.—The import of condensed skimmed milk containing less than 9 per cent. of milk fat is prohibited as from February 5.

Netherlands.—The prohibition of the export of toluene has been removed.

Peru.—The export duty on vanadium ores and concentrates is fixed at £p.4.529 per metric ton, irrespective of their vanadic acid content.

A copy of the new customs tariff and customs regulations, effective as from October 15, 1920, may be seen at the Department.

Rumania.—Export duties have been reduced on rape seed, common soap, and toilet soap.

St. Christopher Nevis.—The revised schedules of customs duties came into operation on January 2. The complete text may be seen at the Department.

San Salvador.—The export duties on sugar, hides, and minerals have been revised.

Senegal.—Groundnuts may now be exported to the U.K. without restriction.

Sierra Leone.—The *ad valorem* import duties have been increased to 20 per cent.

The export duty on palm kernels prescribed by the Order in Council of March 29, 1920, has been revoked.

South Africa.—Asphalt, bitumen, pitch, and preparations thereof imported under item 76*a* of the customs tariff must contain less than 60 per cent. of mineral matter, and heavy oils imported under the same item must not lose more than 10 per cent. of their weight on being heated at 160° C. for 6 hours.

Trinidad.—The export of sugar is prohibited except under licence as from February 14.

Tunis.—The export tax on superphosphates is fixed at 1 franc per metric ton.

LEGAL INTELLIGENCE.

Rail Conveyance Classification of a Washing Powder.—*Joseph Crosfield and Sons, Ltd., v. London and North Western Railway Co.*

On March 4 the Railway and Canal Commissioners dismissed an application by Messrs. J. Crosfield and Sons, Ltd., that their preparation "Carbosil" should be classified in Class 2 for the purpose of railway conveyance. Until July 1, 1917, it had been so classed, but then the railway company decided to classify it as soap powder and charge for it in Class 1.

The case for the railway company was that the applicants had for years enjoyed the advantage of having "Carbosil" carried at Class 2 rates, and that their competitors had objected as all other washing powders were carried in Class 1. Applicants had refused to pay Class 1 rates because they maintained that "Carbosil" was an alkali. The amount of extra rate it was sought to obtain was about £1000 a year, and the business was growing.

In the course of the hearing, counsel for applicants admitted that in 1907-8 "Carbosil" had been advertised as a soap powder, but submitted that throughout the whole period the railway company had carried it in Class 2 with full knowledge of its composition; and it devolved upon the railway company to prove that the increased charge was a reasonable one.

Mr. Justice Lush said that the fact that "Carbosil" had been advertised as a washing powder showed that its classification in Class 1 was correct. On the point of the reasonableness of the increased charge, it was conceded that the railway company had the right to alter a classification after finding out that it had been incorrect; without deciding that question he thought that this was what had been done. He had much doubt if the charge under the Act had been increased at all, but assuming that the onus was on the railway company to prove that the increase was a reasonable one, he thought that it had abundantly proved its case. The applicants were liable for payment of any sums due.

Breach of Contract for the Sale of Calcium Carbide. *Acetylene Corporation of Great Britain, Ltd. v. Canada Carbide Co., Ltd.*

The action brought by the Acetylene Corporation of Great Britain against the Canada Carbide Co. of Montreal for alleged breach of contract in respect of the supply of calcium carbide during the war was terminated on March 9 in the King's Bench Division.

Plaintiff's case was that at the outbreak of war the defendant company had agreed to supply it with calcium carbide on condition that the Corporation had sole control of the sale of all the company's products in this country. The first contract was made for the delivery of 3600 tons beginning in December, 1915, all of which was delivered, but under the second contract only 200 tons was delivered out of a total of 7000 tons. The terms of both contracts stated c.i.f. United Kingdom, and provided that if freight cost more or less than 75s. per ton, the difference should be paid by or allowed to the defendant company. After the price of carbide had begun to rise in the middle of 1916, the company commenced secretly to sell direct to the Admiralty, f.o.b. Montreal, for shipment to this country, alleging that shipping space was not procurable for sending the goods to the Corporation. The latter claimed that shipping space was available, and that it had been declined because the company was supplying to the Admiralty. Hence the Corporation had to buy carbide at £25 per ton in order to fulfil its contracts to sell to the Admiralty at £18 per ton. In 1917 the Admiralty cancelled its contracts with the company, whereupon the latter offered to sell to the Corporation at $20 above the contract price, as it was obtaining $65—95 per ton from the Imperial Munitions Board in Canada. By 1919 the company had repudiated all liabilities under the contracts and had initiated a campaign for the sale of its goods in this country. The result was that the Corporation had to pay £25, £35, and £45 per ton for carbide it had contracted to supply, and that the company made large profits on goods it had contracted to sell to the Corporation at $45 a ton. The Corporation alleged a breach in 1917 and a continuing breach afterwards.

For the defence it was submitted that owing to manufacturing difficulties and lack of shipping space, the suspensory clause contained in the contracts came into operation from 1917 onwards; and that it was not established that the carbide sold to the Canadian War Department was sent to this country and thus came under the contract.

Mr. Justice Rowlatt gave judgment for the Corporation for damages to be ascertained.

TRADE NOTES.

BRITISH.

Canadian Imports.—Despite the adverse rate of exchange that prevailed during the year, the value of imports into Canada from the United States increased very greatly, the increase in the value of imported chemicals and allied products alone amounting to about $6,000,000 over that for the previous year. The fact that imports from the United Kingdom also increased greatly during 1920 show the splendid possibilities that exist in Canada for the development of a market for British goods. The following figures may be of interest in this connexion:—Imports from the United Kingdom into Canada for the twelve months ending November (December totals are not yet available) were valued at $229,925,844, as compared with $84,638,900 for the corresponding period in 1919-20; imports from the United States during the same periods were $927,564,711 and $725,968,553 respectively. Imports of chemicals and allied products, including such items as dyestuffs and explosives, from the United Kingdom for the period in 1920 were valued at $27,030,165, compared with $21,126,643 from all sources in the previous year. Exports to the United Kingdom for the period decreased, while exports to the United States increased, the figures being: to the United Kingdom, $352,083,388, against $514,012,960; to the United States, $545,283,365, against $443,416,125.

Ashanti in 1919.—The chief industries of Ashanti are the production of cocoa, kola, and gold. The cacao plantations suffered from drought and insect pests, factors which are limiting the extension of the crop; the production in 1919 amounted to 31,944 tons, but though this represented a decrease as compared with previous years, the quality showed a marked improvement. The kola crop was up to the average and 6171 tons was exported. Groundnuts have not been cultivated except on an experimental scale, but large areas are available for this purpose. The total yield of dry rubber was 6150 lb.; and 108 tons of skins was exported. Gold production was maintained during the year, the yield being 99,269·76 oz., valued at £421,698, as against 99,278·85 oz., worth £421,736, in 1918. Local industries, *e.g.*, weaving, basket-making, and pottery manufacture, are general throughout the country, but are not exported.—(*Col. Rep.—Ann., No.* 1058, *Jan.*, 1921.)

FOREIGN.

Deliveries of German Potash to America.—The *Deutsche Bergwerks-Zeitung* of February 19 publishes a report that the Potash Syndicate intends meeting America half way in regard to the sale of potash. The unsold stocks of chloride of potassium in America amount to 20,000 tons, and a further 29,000 tons, valued at 47,421,400 mk., is lying at German harbours ready for despatch. In order to put an end to the dispute concerning the " Baisse clause," the German Potash Syndicate intends to deliver 40 per cent. of the amount of potash already delivered at a rate far below that agreed upon for the old contracts. Owing to the depreciation of the American exchange, large sums of money have been lost on the 20,000 tons lying in America, the value of which is estimated at $1,043,357, and the German Potash Syndicate, by these supplementary deliveries, wishes to make good to a certain extent these American losses in order to create a new basis for trade.—(*Official.*)

The Chinese Soap Trade.—The use of washing soap in China is practically limited to the areas at or near treaty ports and large trading centres. In the interior a kind of vegetable soap, known as soap bean, is used in laundry work. Imported soaps were formerly widely sold in the treaty ports and outlying districts, but have now to face considerable competition from native products. Some 60,000 cases of soap are produced yearly in Hankow by four native soap works, which are equipped with little or no machinery. Foreign firms that sell soap in China require cash in advance, whereas the native manufacturer sells on consignment and allows long credits and other facilities, with the result that several foreign soaps no longer command a market. The imports of washing soap in 1913, 1915, 1917, and 1919 amounted to 1029, 916, 1099, and 468 tons, respectively. There are almost unlimited possibilities for the development of this industry, and the abundance and cheap supplies of both raw materials and labour would suggest the establishment of foreign-owned factories in China. Apparently the possibilities of developing the toilet-soap trade are even greater, and the establishment of a factory in China for this purpose would doubtless meet with success. The value of the imports of toilet soap in 1919 was £48,148.—(*U.S. Com. Rep., Dec.* 20, 1920.)

Foreign Company News.—*Czecho-Slovakia.*—A group of German textile manufacturers has formed a new company in Prague to manufacture artificial silk.—(*U.S. Com. Rep., Dec.* 13, 1920.)

France.—The capital of the Société Chimiques des Usines du Rhône is to be increased to 21 million francs.

The Compagnie Nationale de l'Azote (capital 12,500,000 fr.) has been formed to take over the contract made between the French Ministry of Reconstruction and the Badische Anilin- und Soda-fabrik for the exploitation of the company's process of manufacturing synthetic ammonia and derivatives thereof (*cf.* J., 1920, 305 R). The directorate of the new company includes representatives of various banks, the Cie. des Mines de Béthune, the Cie. Nationale des Matières Colorantes et de Produits Chimiques, the Etablissements Kuhlmann, the Société des Products Azotés, and Solvay et Cie. (Brussels).—(*Rev. Prod. Chim., Jan.* 31, *Feb.* 15, 1921.)

The Upper Alsatian Potash Mines (Société des Mines de Potasse du Haut-Rhin, Société par actions à Mulhouse) has just formed a subsidiary company with a capital of 1,500,000 fr. to exploit the potash mines in Alsace, which will endeavour to acquire all mining concessions, mines or works, whether belonging to companies, private persons of the State. The original capital is 1,500,000 francs.—(*Deutsch. Bergwerks-Z., Feb.* 19, 1921.)

United States.—It is announced that the Society of Chemical Industry in Basle has decided to enlarge the Ciba Co., Inc., and to take over the whole organisation and branches of the Aniline Dyes and Chemicals, Inc. The Ciba Co. will distribute both the Swiss and American dyes. The factories owned by the Society of Chemical Industry in Basle are situated at Basle, Petite Huningue and Monthey in Switzerland, at St. Fons, in France, Pabianice in Poland, Moscow in Russia, Manchester in England, and Cincinnati in the United States.—(*Oil, Paint and Drug Rep., Feb.* 7, 1921.)

REVIEWS.

Introduction to Qualitative Chemical Analysis. *By* Th. W. Fresenius. *Seventeenth edition of the original work by* C. R. Fresenius. *Translated by* C. A. Mitchell. *Pp.* 954. (*London: J. and A. Churchill.* 1921.) *Price* 36*s. net.*

The appearance of an English translation of the seventeenth German edition of Fresenius's " Qualitative Analysis " will be welcomed by all English-speaking chemists. The present volume is twice the size of its predecessor, published in 1897, and there is much alteration in detail, although the same general plan is maintained. Part I deals with chemical principles and methods and the behaviour of substances towards reagents. Here are brief accounts of physico-chemical theory as it affects analysis and of the operations of the laboratory. Then follow the reactions of kations and anions, including those of the rare elements and various organic acids. Part II is concerned with the systematic course of analysis and embraces practical methods of the general course and for special cases, together with explanatory notes. Lastly, the appendix includes the reactions of alkaloids and glucosides, remarks on the choice of exercises, the method of tabulating results, and solubility tables. There is an adequate index.

The guiding principle of the book is denoted by these words from the preface:—" Chemical analysis demands a knowledge of the fundamental laws of general chemistry, of analytical operations, and of the behaviour of individual substances towards reagents. Given these essentials, it is possible, with the aid of a systematic procedure, to undertake the investigation of unknown substances." The whole volume is an elaboration on a most extensive scale of this fundamental thesis.

Perhaps the analyst will find the book too large to be a bench companion, but in this case he will desire to have it near for reference, because it is a chemical classic which has been brought thoroughly up to date. Especially noteworthy is the information regarding the chemical reactions of the rare metals; probably in no other place can this information be obtained in so convenient and extensive a form. An improvement on former editions is the inclusion of tables of separation for the successive groups of metals.

A few comments on details may be made. The use of iron is quite the simplest method of separating antimony from tin, and the beginner can hardly fail to succeed with it; but most of the acid used to dissolve the two sulphides should be removed or neutralised to facilitate the reduction of the antimonious solution by the iron. The method of separating calcium from strontium by ferrocyanide is interesting and little known. The statement (p. 630) that permanganate may be formed when a manganese compound is fused with potassium chlorate and sodium carbonate cannot pass; manganate, not permanganate, is the stable salt under

these conditions; indeed, potassium permanganate is converted into manganate when fused with alkali carbonate even in presence of chlorate.

On pp. 634–5 it is said that the ammonium sulphide precipitate may possibly contain, not only hydroxides and sulphides of various metals, but also phosphates, borates, oxalates, silicates, and fluorides; and there follows a very elaborate scheme for the separation of all these components. It is unnecessary for this precipitate to contain any of the latter salts, and the elaboration may consequently be avoided.

By various means interfering anions can be eliminated from solution before testing for kations, just as interfering kations are eliminated, by means of sodium carbonate, before testing for anions.

On p. 113 the compounds $HAuCl_4$ and H_2PtCl_6 are wrongly called aurohydrochloric acid and platinohydrochloric acid respectively; and on p. 199 the salts of tervalent titanium are unfortunately called titanic salts.

The translator and publishers are to be congratulated on their work. The style and arrangement leave nothing to be desired. It is necessary, however, to call attention to one blemish, viz., that some of the formulæ are misprinted. In the table above referred to (pp. 634–5) the following erroneous formulæ occur: $H_3B_2O_3$, $K_2Co(NO_2)_6$, CaF_3, $Ba_3(PO_4)_3$, $Mg(NH)_4PO_4$; and there are a few other similar errors elsewhere. Small defects like the above, however, scarcely detract from the value of so great a work.

R. M. Caven.

Chemistry of Pulp and Paper Making. *By* E. Sutermeister. *Pp.* 479, *with* 55 *text-figures and* 31 *plates.* (*New York: John Wiley and Sons; London: Chapman and Hall.* 1920.) *Price* 33*s. net.*

This volume has been prepared "with the idea of helping the young technical man, whether chemist or chemical engineer," in the pulp and paper industry. The author is a well-known mill chemist of some twenty years' experience, and the book is based on his "personal notes and experiences" collected during that period.

As a scientific introduction to the chemistry of the industry it falls below the level of Griffin and Little's "Chemistry of Paper Making" (now old and out of print), and as a manual of technology cannot be classed with Cross and Bevan's "Text Book of Paper Making" (fifth edition, 1920). We make this comparison because in our opinion these are the two text-books which have had the most influence on the industry in America and England, and also because the general arrangement and aim of the book now before us follow on the lines laid down in these "classics" of paper-making.

On the whole, this book may be fairly described as a mill chemist's note-book, based on a limited but practical experience of the industry, arranged on a well-conceived plan, and enlarged by copious references to current literature on the subject. Its chief points of interest to the paper-mill chemist in this country are:—(1) An excellent and concise account of American woods and wood-pulp processes (comprising about one-third of the volume); (2) about two dozen well-reproduced half-tone plates of paper-making fibres (from photomicrographs); (3) the numerous references (over 300) to technical literature given in the foot-notes; and (4) indications of American practice in certain routine tests from which some very useful hints may be gathered by the practical man who has sufficient experience to read between the lines.

The author writes in a simple and clear style, but we do not consider his habit of stating inconsistent conclusions suitable to the young student. For example, his claim (p. 250) that bleached sulphite possesses greater strength than the unbleached fibre, compared with his statement (p. 252) that the more bleach used the greater will be the attack on the cellulose, is confusing. The first parapraph on rosin (p. 264) contains an obvious mis-statement concerning reasons for selection of the grades used in sizing.

From the consulting chemist's point of view this volume is a commentary on a certain aspect of the technical chemist's work. It is neither pure nor practical chemistry, and applied chemistry is only incidental and explanatory. The successful paper-mill "chemist" is expected to have a knowledge of practical botany, mineralogy, engineering, and physics in addition to chemistry, and his chemical analyses are done largely to interpret and confirm the results of physical tests.

The author presents much valuable information in a readable and handsome form, but we do not consider that he succeeds in attaining fully the aims outlined in the title and preface.

James Strachan.

The Practice of Lubrication. *By* T. C. Thomsen. *Pp.* x.+607. (*New York and London: McGraw-Hill Book Co., Inc.* 1920.) *Price* 36*s. net.*

Mr. Thomsen in his preface rightly states that lubrication has for many years received only scant attention. Surely this was inevitable so long as lubricating oil companies regarded the scientist as an unnecessary adjunct to their advancement. Now that the engineer is demanding more exact information about the oil he uses, there is a growing feeling that more chemists are needed to investigate the many problems presented. Lately several well-known workers in the industry have written books to meet the growing demand for knowledge, and Mr. Thomsen is one of them. Mr. Thomsen's opportunities for acquiring information on lubricating systems have probably been unique; therefore, a record of his experiences is very welcome.

The book is designed chiefly for the engineer, but since the chemist is called upon to understand lubricating systems, it must also appeal to the chemist. The engineering sections are really well done, and the illustrations are very clear. The chemical portion is scanty, but doubtless this was deliberate, as the main object of the book was to deal with the actual use and application of lubricants in practice. There is just a hint, however, in the preface that the chemist is merely an assistant to the engineer!

From time to time various theories have been advanced to explain the production of acids and of solid deposits from mineral oil, and perhaps the belief that the unsaturated hydrocarbons are the progenitors of these decomposition products has been the most popular. The theory appears to have been based upon speculative arguments and not upon experimental results. Thomsen's faith in this theory appears to be evident from the fact that he states that hydrocarbons of the formulæ C_nH_{2n-2} and C_nH_{2n-4} are more or less unsaturated; in fact the former group is characterised by the acetylene linkage. Further, he states that the colour of an oil is due to the presence of unsaturated hydrocarbons, and that colour is a criterion of the stability of an oil. It does not require much experimental work to shed considerable doubt upon the accuracy of these statements.

One would prefer to have seen the word "adsorbed" instead of "absorbed" on page 9; and on page 14 it would have been better to state that nitronaphthalene masks the fluorescence instead of removes it. The apparatus described on p. 591 was surely designed at the National Physical Laboratory, and that which Thomsen suggested and described in the J. Inst. Elect Eng., 50 (1915), 239,

155, is quite different from this. In this connexion it might be suggested that a few references to other workers would enhance the value of the book.

The large number of oil specifications are of great value, although in some cases differences of opinion may be expected. The inclusion of the subject of oil consumption is also very valuable, but no doubt the reader will be astonished at the wide limits given; but these are inevitable owing to the different conditions prevailing in engines of even the same class.

Whenever a chemist is called up to report upon a lubricant, he will benefit by referring to "The Practice of Lubrication" before appending his signature.

E. A. Evans.

Bibliotheca Chemico-Mathematica. *Catalogue of Works in Many Tongues on Exact and Applied Science, with a Subject-Index. Compiled and Annotated by* H. Z. *and* H. C. S. *Two volumes. Pp.* xii+964. *(London: Henry Sotheran and Co.* 1921.) *Price* 63*s. net.*

These volumes are of so unusual a nature that they are worthy of detailed notice. The main contents of the work were first issued as a series of annotated sale catalogues, and in their original form they were of considerable value to bibliographers and librarians for reference purposes. Their publication in two well-bound volumes, together with an adequate subject index, should increase the scope of their usefulness. The addition of portraits and facsimiles of high artistic and technical merit adds to their attractive character. The portrait of Dr. Thomas Young is a particularly fine example of photo-reproduction. The biographical and descriptive references are both interesting and instructive, though it is a pity that extraneous comments were introduced in the last few pages published during the war. We may agree with the sentiments, but the remarks hardly appear to have any direct connexion with the items to which they are attached.

In view of the large field covered by these volumes, it is not remarkable that a few inaccuracies occur. On page 208 there is a statement that only one volume was published by the Royal College of Chemistry, that of 1845-7, whereas a second was published in 1853, covering the years 1848–51. That Storer's Dictionary, Cambridge (Mass.), is "the only dictionary of chemical solubilities ever attempted" is also erroneous, as one was compiled by Comey in 1896, and another by Seidell in 1907 (2nd edition 1920). The first edition of Accum's "Chemical Amusement" is dated 1819, but as the copy contains a list of chemical apparatus not included in the 1819 edition, this is obviously a misprint for 1817.

The mention of a "neatly written" MS. as possibly the one used by Robison when compiling his edition of Black's Lectures suggests the speculation as to how many of these manuscript copies are still in existence. From time to time the writer has come across these MSS., the owners of which fondly supposed that their copy was either the original, or that of Robison. Reference to Robison's preface shows that the former consisted of single octavo leaves, full of erasures and difficult of transcription, whilst the latter contained whole pages and many alterations in Black's autograph, so that either should be easily identified.

Messrs. Sotheran are to be congratulated on their enterprise in producing a catalogue of books which is also a record of permanent utility, and by publishing it in its present form they have rendered a distinct service to those interested in the history and bibliography of science.

F. W. Clifford.

OBITUARY.

S. H. BLICHFELDT.

By the death of Sören Höy Blichfeldt at the early age of 44, the margarine industry loses one of its ablest technologists. Blichfeldt, who was Danish by birth, graduated from the Royal Pharmaceutical College, Copenhagen, and came to England in 1906 to take up the position of technologist to the Maypole Works at Southall. He had previously been engaged for a few years on bacteriological and fermentation research work, and having a remarkable gift of applying science in the works he was able very soon to improve and develop methods of manufacture. This service was rendered not merely in the narrower sphere of his company, but in the wider interests of the margarine industry generally.

S. H. Blichfeldt's name will be familiar to members as a contributor to the Society's literature, and one could not meet him without being impressed by the great fertility of his mind and his wonderful power of conceiving methods and processes. Many men with faculties so fully developed are so absorbed in their theories that all else in life is excluded; but Blichfeldt was a keen sportsman, a skilled musician and, to all who knew him, a charming companion—a wonderful combination which makes his loss the more keenly felt by his colleagues and friends.

E. Skjold.

Corrigendum.—In the last issue, p. 97 R, col. ii., in the sixth line from top, read "geranial" instead of "geraniol."

SOCIETY OF CHEMICAL INDUSTRY.

THE ANNUAL MEETING, 1921.

MESSAGE FROM THE PRESIDENT.

As has already been announced, the next annual meeting of the Society of Chemical Industry will be held in Canada, in response to a very hearty invitation extended by the Montreal Section; the formal meeting extends from August 29 to August 31, but our Canadian friends have expressed the wish that the party from Europe will arrive a few days earlier so that they may be shown some parts of Canada not included in the extensive official programme now being compiled. It will thus be convenient if as many of the visitors as possible will travel with me by the "Melita," which leaves Liverpool on Friday, August 12, and arrives at Montreal on or after August 22.

At the close of the business meeting on August 31, the members will leave Montreal by a special train for a four days' triangular tour of Eastern Canada, during which visits will be paid to the paper and pulp works at Grand Mere, the largest in Canada, to the carbide and synthetic-acetic-acid factories at Shawinigan, and possibly to the aluminium and magnesium electrolytic plants. September 2 will be spent at Ottawa and the next two days at Toronto. A boat trip across the Lake has been arranged in connexion with a visit to Niagara and to the chemical works and fruit farms on the Canadian side of the river. September 6 will be spent in an inspection of the electrochemical works on the American side of the Niagara Falls, and the party will then proceed by train to New York.

From September 7 to September 10 the party will co-operate in a joint meeting of the Society of Chemical Industry and its American Section and the American Chemical Society; it will visit the great Chemical Exposition which opens at New York on September 12, and which will certainly be one of the most important exhibitions of the chemical industry which has ever been held.

During the critical period through which all branches of the chemical industry are at present passing, when old markets are falling away and must be replaced by new ones, it is more than ever essential that British industrial chemists should seize every opportunity of gaining acquaintance with the conditions which prevail in the British Dominions and abroad; only by personal visits and by the establishment of new friendships and fresh business relationships can our members hope to be able to raise our chemical industries to the position indicated for them by the history and the geographical environment of these islands. Our Canadian and American friends have intimated their desire to furnish uncommonly extensive facilities for the inspection of works concerned with every branch of chemical industry, and it is certain that similar facilities cannot be granted to private individuals travelling alone apart from an official party such as is now being formed. The Council therefore desires to urge the members of our Society to make every effort to accept the generous invitation extended to us by our transatlantic friends; we are convinced that the maximum benefit to our Society and to the chemical industries of Great Britain, of Canada, and of the United States can only be derived by the attendance of a large British party at the coming annual meeting.

WILLIAM J. POPE.

Supplementary to the provisional programme which appeared in the *Journal* for December 15 last, we are now able to give the following details concerning the arrangements which have been made for the period August 26—31, to be spent at Montreal:—

Friday and Saturday, August 26—27:—Reception Committee meets Visitors.

Sunday, August 28:—Golf. Motor-trip around City and Island.

Monday, August 29:—

Morning: 10 a.m., Council Meeting at McGill University; 11 a.m., Annual Meeting. (a) Address of Welcome; (b) Reply; (c) General Business of the Society.

Afternoon: 1 p.m., Civic Reception and Lunch. 3 p.m., Special Visit to McDonald Agricultural College. Supper and Garden Party.

Tuesday, August 30:—

Morning: 10.30 a.m., (a) Address by a prominent Canadian chemist; (b) Pulp and Paper Symposium (3 papers).

Afternoon: 1 p.m., Luncheon at Windsor Hotel, given by Montreal Section. 3 p.m., Visits to various industrial plants.

Evening: 7.30 p.m., Banquet at Windsor Hotel.

Wednesday, August 31:—

Morning: 10 a.m., Special Addresses and Technical Papers.

Afternoon: 1 p.m., Luncheon at Windsor Hotel given by Montreal Section. 3 p.m., Special Convocation at McGill University. 4 p.m., Trip down Lachine Rapids.

Evening: 11.55 p.m., Leave by night train for Shawinigan.

NEWS FROM THE SECTIONS.

SHAWINIGAN FALLS.

At a meeting held on March 12, Dr. F. W. Skirrow presiding, Dr. John S. Bates, formerly director of the Forest Products Laboratories of Canada, gave an address on "Pulp and Paper."

The subject of forestry should be taken more seriously by the public, because the time has come when plans must be carried out on a large scale to protect and reproduce our crop of trees for all the wood-using industries. Canada's reserves of timber rank next to those of Russia and the United States, but even this strong position must be protected to ensure permanent supplies for the Dominion and the rest of the world. Forest fires have burned down ten times as many trees as the loggers have felled. In the east there are still large supplies of pulpwood trees, but British Columbia has most of the big timber. Fortunately, over 90 per cent. of the timber land remains under Government ownership, and the problem is fairly simple if the public will only demand and assist State action in conserving the timber resources. As over two-thirds of the land area in the settled portion of Canada is unfit for agriculture, there is ample scope for development.

The pulp and paper industry now heads the list of manufactures in Canada, and also leads all others in export trade. This may be traced directly to the natural resources of pulpwood and water power. To a large extent paper is made from raw materials not suitable for other purposes. Cotton goes into textiles, and the waste clippings, rags and linters supply the higher-grade paper mills. The best trees are cut into lumber, but the smaller sizes and inferior species are good enough for most grades of paper products. The problem in making paper pulp is to dissolve out the lignin and other carbohydrates in the wood, and to separate the flexible fibres of white cellulose. Wood is the outstanding source of fibre for papermaking, because the length of the natural fibre is just right, the yields of pulp are high, wood is cheap, abundant and compact, and, finally, it floats down our rivers

and is easily handled. The conifers such as spruce, balsam fir, hemlock, and jack pine are low in resin content, and have fibres about ⅛ in. long and 0·01 in. wide. The hardwoods such as poplar, basswood, and birch are more resistant to pulping, and have fibres about one-third the size of the softwoods, so that their use is more limited.

The speaker then outlined the groundwood, sulphite, sulphate, and soda processes by which wood is converted into mechanical and chemical pulp. The characteristic properties of the different kinds of pulp fibres were illustrated by samples of paper pie-plates, newsprint, wrapping paper, board products, magazine paper, writing paper, and bank-note paper. The methods of beating, bleaching, sizing, and loading to give the desired formation and finish were described. In conclusion, the scientific trend of the industry in the direction of improvements in processes and machinery, saving of by-products, and quality of products was pointed out.

BRISTOL AND SOUTH WALES.

A meeting was held at the University College, Cardiff, on March 4, with Prof. C. M. Thompson in the chair. Mr. Donald Brown read a paper on "Paper-making," in which he described the various processes employed from the felling of the timber in Sweden to the finished roll, and explained the different types of machinery used. The paper had special reference to the Ely Paper Mills, Cardiff, which were subsequently visited by the Section on March 10, by the courtesy of Messrs. T. Owen and Co., Ltd.

At Bristol on March 17, Mr. E. Walls (chairman) gave an address on "Chemical Industry in Bristol."

Except for the purely engineering, boot manufacturing and clothing trades, there was no productive industry in Bristol which was not interested in technological chemistry. Chemical engineering was strongly represented in gas manufacture, an industry which was introduced into their city in 1811 by a Mr. Briellat, who was accused of having "unholy dealings with an infernal power." The Bristol Gas Co. started operations in 1816 with a capital of £5000 and experienced many vicissitudes (among which was the refusal to lay pipes on account of the danger), but it outlived the competition of a works which started producing oil gas in 1824. The local tanning industry derived much benefit from the importation of hides from Ireland, and the oil, paint, and varnish industry probably owed its origin to local supplies of ochre and importation of logwood from the Indies. Floorcloth, the forerunner of linoleum, was introduced in Bristol by John Hare in 1782. The fame of Bristol brewing went back many centuries. The distillation of petroleum for toluene was carried out on an enormous scale during the war; in fact, no less than 80 per cent. of the total output of toluene in 1915 was produced at Portishead, the plant for which was shipped *en bloc* from Rotterdam. Alcohol was distilled locally for munitions purposes during the war, as were also aromatic hydrocarbons, phenol, and glycerin. At Netham there was the large plant of the United Alkali Co. producing soda by the Leblanc process, also caustic soda, chlorine, bleaching powder, sulphuric acid and other products. Glass-making was an old-established Bristol industry largely engaged in making bottles for imported wine; in 1797 there were 14 glass works in operation. The Avonmouth works, erected during the war, might have given Bristol a preponderating position in chemical industry, the total capacity of the sulphuric acid plant being sufficient to supply the whole requirements of Europe, but, unfortunately, it had been closed down. In fine chemicals they had no standing, but Bristol had always been a pharmaceutical centre. The refining of copper and manufacture of brass from cupriferous residues from Cornish tin-ore was started about 1705, calamine from the Mendip mines being also used. The brass-wire industry was developed on a large scale, and in 1712 it was stated that the brass and copper works consumed 2400 tons of coal per week. There was also an important lead industry in the 17th and 18th centuries. The oldest chemical industry in Bristol was soap manufacture, which dated back to the 13th or 14th century; this industry suffered severely in 1631 when the King granted the monopoly of soap-making to certain Londoners. In conclusion, Mr. Walls referred to the help which the local chemical industries and the Section had received from the Chemical Department of the University, and stated that with such assistance there should be a bright future for chemical industry in Bristol.

GLASGOW.

At an informal meeting of the Section held on March 9, Mr. J. H. Young presiding, Mr. Crooks read a paper on the "Electric Charge on Colloids." Reference was made to the importance of Colloid Chemistry and the growing necessity for all technical chemists to have a sound knowledge of the subject in view of the fact that many of the processes which the chemist controls deal with colloidal phenomena. The work of Graham was mentioned, and emphasis was laid on the fact that the term "colloid" connotes a "state" and not a "form" of matter, and that many of Graham's crystalloids have, by various methods, been obtained in the colloidal state.

Malfitano's work on the conductivity of sols after filtration through a collodion membrane was referred to, but it was pointed out that his method was open to objection as the filtration might change the concentration of the medium as well as remove the disperse phase. The method of prolonged electrolysis used by Whitney and Blake was recommended as a more suitable method. The necessary precautions to be taken in observing migration velocities were fully discussed. The action of electrolytes on sols was described and the "Valency Rule" generalisation enunciated and explained. Burton's estimation of the charge on a colloid particle (by assuming that the amount of aluminium ion necessary to precipitate a certain amount of a sol carried the same amount of positive electricity as the precipitated colloid did of negative) was also dealt with. In concluding, reference was made to the theories regarding the electrical charge, particular attention being given to the "differential diffusion" explanation of Taylor, the more or less generally accepted "adsorption" explanation, and Burton and Hardy's explanation for the oxidisable and non-oxidisable metals.

A paper on "Lead Corrosion" was read by Mr. W. G. McKellar.

NEWCASTLE.

Two papers were read at the meeting held on March 23. Mr. C. F. Tidman re-read the paper on "Alcohol from Coke-oven Gas," which he had previously read at Middlesbrough on March 7 (*cf.* J., 1921, 103 R), and Mr. C. L. Haddon contributed a paper on "The Effect of Some Physical Conditions on Calcium Sulphate Cement." Prof. P. Phillips Bedson presided.

Mr. Haddon has carried out tests on the expansion of a flooring plaster consisting of 3 parts of plaster to 1 part of water or of a 5 per cent. solution of calcium chloride, potassium sulphate, or ferrous sulphate. Le Chatelier's apparatus was used, and no measurements were made with the cement in a plastic state. He found that expansion was least with accelerating solutions and

greatest when retarders were employed. With the potassium sulphate solution, wet-set plaster continued to expand during recrystallisation. Both the degree of wetness and the amount of expansion have an effect on the tensile strength; briquettes which had expanded 5 per cent. had less than a quarter of the strength of similar briquettes allowed to dry in air (when the expansion is very much less). Under normal conditions, expansion does not exceed about 0.1 per cent., and ceases within the time required for complete setting.

The weakening of flooring plaster was investigated by immersing briquettes (after six hours' immersion in water and air-drying) in various liquids for definite times and then breaking them. It was found that mineral oils were without effect, but the tensile strength was reduced by mixtures of methylated spirit and water to an extent varying with the amount of water in the mixture. The strength was reduced by over one-half by water and by a concentrated solution of calcium sulphate. Similar results were found for crushing strengths.

The value of the published data on the mechanical strength of flooring plaster is impaired by the circumstance that no standard has been laid down concerning the condition of the briquette on breaking, and it is suggested that the method used in testing Portland cement should be generally adopted, and that the proportion of flooring plaster to water should be 3:1 by weight.

MANCHESTER.

The annual meeting was held at the Textile Institute, Manchester, on April 1, Mr. John Allan presiding. Five members of the committee retired, and as there were seven nominations to fill the five vacancies a ballot was taken; Messrs. R. H. Clayton, J. R. Hannay, W. B. Hart, J. A. R. Henderson, and J. Huebner were elected.

The Hon. Secretary, Mr. L. Guy Radcliffe, then read his report for the session 1919–21, which stated that the original syllabus, issued last August, arranging for eight meetings and about twelve papers, had been carried out with very few alterations. The change of meeting-place from the Grand Hotel to the Textile Institute, which was decided upon by a unanimous vote of the members present at the February meeting, has had the success anticipated, and the Section has now the advantage of an excellent locality for scientific meetings and social intercourse. The numerical strength of the Section has diminished in spite of many new members having joined the Society. About 20 members were lost by resignations, and 5 by deaths, but removals from the district were very numerous, and the membership now stands at about 620. The committee has elected Dr. E. Ardern to be chairman in place of Mr. John Allan, who now becomes vice-chairman in succession to Mr. W. Thomson, and the hon. secretary was re-elected for a further year. The report also refers to the annual dinner held in November and the annual supper held in March.

At the ordinary monthly meeting which followed, Mr. H. J. Bailey, formerly of the Explosives Department of the Ministry of Munitions, read a statistical paper on "Sulphuric Acid during the War Period." It was shown that whereas the production of sulphuric acid in the United Kingdom is normally about one million tons per annum of 100 per cent. strength, 1,208,000 t. was produced during 1916 in chamber-acid plants; and that the production of concentrated or fuming sulphuric acid made in contact-acid plants reached 221,000 t. during the year 1917.

The raw materials for the manufacture of sulphuric acid were dealt with, and tables were given showing the various main uses in the heavy chemical industries of the country. In addition, summarised statistics were given of the consumption of sulphuric acid in the manufacture of the various types of explosives, and it was shown that in the period 1916 to 1918 the overall consumption per lb. of explosive manufactured was reduced to less than one-half of that used during 1915 by obtaining increased efficiencies and necessary economies in working.

The author also discussed the production and use of fertilisers during the stressful period of the submarine menace in 1917–18, and showed that whereas during the first two years of the war the manufacture had seriously declined, before the war had ended the full pre-war production had been surpassed, thus enabling much larger supplies of sulphate of ammonia to be available for agriculture.

LONDON.

At a meeting held on April 4 at Burlington House, with Mr. Julian L. Baker in the chair, a paper entitled "The Scientific Principles of Cold Storage" was read by Prof. W. Stiles.

Food materials that can be preserved by cold storage—and they are the majority—may be roughly divided into:—(a) Those, such as fruit, which deteriorate on freezing and therefore must not be cooled below 0° C.; and (b) those, such as mutton and rabbits, which, after being frozen solid, practically revert to their original condition on thawing. A few materials, *e.g.*, beef and some species of fish, occupy an intermediate position. Cold storage above 0° C. allows enzyme and other actions, which may lead to deterioration, to continue, but below this temperature these processes are stopped or greatly retarded. Further advantages of frozen storage are:—Longer preservation, the possibility of close packing, and the small amount of supervision required. One of the greatest problems of cold storage is therefore to devise means by which materials belonging to class (a) may be stored in a frozen condition instead of at temperatures above 0° C.

The cold storage of fruit is influenced by variation in the rate of cooling, light, relative humidity, movement of the air, and other factors. Even at 0° C. biochemical changes take place which result in the conversion of carbohydrates and organic acids into other substances, and the production of carbon dioxide by respiration. The rate of respiration is greatest in those fruits that keep in cold storage for the shortest time, and this rate is doubled for an increase of temperature of 8° C. Although chemical changes are reduced by cooling, all reactions are not depressed to the same extent. Fruit may be chilled slightly below 0° C. without freezing, owing partly to the lowering of the freezing point by the salts etc. present in the juices, and partly to the effect of the small amount of heat produced by respiration. When rotting commences the temperature of the fruit increases rapidly. In storage by freezing, the change from liquid to solid is not completely reversible on thawing, and with beef and fish, water separates which runs out on thawing, thus leading to loss of soluble substances and probably causing toughness. The rate of cooling much affects the condition after thawing, and experiment has proved that with rapid chilling the changes produced are reversible on subsequent thawing. Although agitation of the cooling medium has little effect upon the rate of cooling, this property is largely influenced by the conductibility for heat of the medium. Gases are unsatisfactory, and the most efficient practicable media are water and aqueous solutions of common salt, calcium chloride or magnesium chloride. Materials of small bulk, such as fish or small joints of meat, are very effectively frozen in brine, but with larger pieces the outer layers are often dull in

colour, although the salt present is insufficient to affect the flavour after cooking. Calcium and magnesium chlorides may give rise to a bitter flavour. But little experimental work has so far been done in this subject, and its extension would prove of the greatest value to all civilised races.

JAPANESE CHEMICAL INDUSTRIES FROM THE STANDPOINT OF FOREIGN TRADE.

As is well known, the chemical and allied industries of Japan underwent a sudden and great development during the war, owing mainly to the country being cut off from extraneous sources of supply, but also to the great demand for warlike materials. The progress achieved is well reflected in the following statistics of foreign trade, which afford a comparison between the average yearly trade during the three years immediately preceding the war and the trade in 1918. During this period the value of the imported chemicals, etc. rose from 63 million to 93·4 million yen, an increase of 47 per cent., and that of the exports increased from an average of 51·56 to 246·79 million yen, a gain of 378 per cent. The appended table gives some details (the negative sign indicates a decrease, and the yen is taken at 2s.):—

	Imports. Total inc. or dec.	Imports. Rate per cent.	Exports. Total inc. or dec.	Exports. Rate per cent.
Sugar	£216,200	356	£1,385,000	133
Leather	111,300	36	940,000	753
Oils and waxes	181,300	39	3,420,000	426
Chemicals and drugs	2,394,600	227	2,856,900	474
Explosives	160,900	183	1,708,200	150
Dyestuffs	417,600	58	—	—
Pigments	129,900	95	1,024,800	2601
Paints	27,400	16		
Rubber	−104,600	−42	—	—
Celluloid	−426,000	−100	—	—
Photographic materials	101,800	104	—	—
Paper	502,900	45	2,654,100	857
Porcelain	−1,800	−18	1,413,500	242
Glass	−134,600	−42	1,296,600	416
Enamelled ware	−3,800	−100	—	—
Bricks	−400	−2	—	—
Cement	—	—	560,200	1376
Electric-furnace products	117,400	970	—	—
Fertilisers	−1,269,200	−98	21,900	32
Total	£2,985,400	47%	£19,522,800	378%

It will be observed that very remarkable increases occurred in the imports of chemicals and drugs, dyestuffs, paper, sugar, oil and wax, leather, explosives, pigments, photographic materials, and electric-furnace products. On the other hand, celluloid, enamelled ware, and fertilisers all showed noteworthy decreases. Of the chemicals, very large quantities of soda ash, caustic soda and soap were imported, although production has increased to such an extent that at the present time Japan can supply 80 per cent. of her consumption of caustic soda from home sources. The increases shown are to a very large extent due to the enormous rise in market prices; the quantities imported actually diminished.

The following figures show the percentage value of the imported chemical products compared with the total value of the whole import trade of the country:—

	Average of 3 pre-war years.	1918.
(a) Total imports	£61,990,500	£166,814,200
(b) Technical products	—	67,386,700
(c) Chemical products	6,354,900	9,340,300
Ratio of (c) to (a)	10.1%	5.6%

The largest increase in the value of exported products was obtained by the oil and wax industry, mainly as a result of the new export trade in palm oil, rapeseed oil, and soap. The chief increases in chemicals and drugs were in calcium carbide, acetic acid, and potassium chlorate. The ratio of the average value of the chemicals, etc. exported before the war to the whole export trade rose from 9·6 to 12·2 per cent.:—

	Average of 3 pre-war years.	1918.
(a) Total exports	£53,562,500	£196,210,000
(b) Technical products	—	£172,890,000
(c) Chemical products	5,156,500	24,679,400
Ratio of (c) to (b)	—	14.1%
Ratio of (c) to (a)	9.6%	12.2%

The most important countries of destination of exported Japanese chemical products are China, India, Oceania, and South America.

THE INTERNATIONAL NORMAL WEIGHT FOR THE SACCHARIMETER.

At the present time the normal weight that is in almost universal use for the saccharimeter (or polarimeter reading the percentage of sugar directly) is 26·0 grams, this standard having been adopted by the International Commission for Uniform Methods of Sugar Analysis in 1900. On dissolving 26·0 grams of pure sucrose in water, and making the liquid up to 100 metric c.c. at 20° C., a solution is obtained which in a 200-mm. tube reads exactly 100·0 scale divisions corresponding with $34·657 \pm 0·023$ angular degrees with spectrally purified sodium light. In France a normal weight of 16·29 grams is largely used.

The proposal was, however, recently made by Dr. C. A. Browne and other American chemists to adopt a sugar scale having a normal weight of 20 grams, the principal advantages claimed being:—(1) It is a compromise between the 26·0 and 16·29 gram scales; (2) the results obtained are easily converted into percentages by multiplying by 5; (3) aliquot portions of 50, 25, 20, and 5 c.c. of the 20 per cent. solution represent even gram quantities; and (4) the specific rotation of sucrose at a concentration of 20 grams. in 100 c.c. (18·62 per cent. by weight) is about the maximum. It was further argued that the factor for conversion into circular degrees, namely $100 = 34·657$, is inaccurate in view of the work of Bates and Jackson published in 1916, and that the present is an opportune time for adopting a new factor and a new standard. French chemists decided to support their American colleagues in adopting the 20 gram normal weight.

In order to elicit the opinion of British chemists in the matter, a committee was formed consisting of the following:—Prof. Arthur R. Ling (chairman), Prof. Thomas Gray, and Messrs. L. J. de Whalley, Hugh Main, and J. P. Ogilvie (secretary). This committee drew up a statement of the arguments *pro et contra*, nearly 2000 copies of which were sent to chemists engaged in the sugar and allied industries, both in this country and in the British Dominions.

An analysis of the replies received shows about 72 per cent. of the correspondents to be opposed to the adoption of the new standard. Most of these replies stated as the reason for the decision that the advantages claimed for the proposed new standard were too slight to compensate for the considerable inconvenience, expense, and confusion that would (it was considered) be involved by its adoption. A very frequent additional reason was that, owing to the smaller amount of sample taken for the assay, the accuracy of observation would be diminished. In an addendum to his reply, Mr. A. F.

Blake, Chief Chemist, Atlantic Sugar Refineries, Ltd., St. John, N.B., Canada, said that he thought the 26-gram value should be retained regardless of whether Herzfeld's or Bates and Jackson's factor is the correct one, or whether future investigations provide still another, "new instruments being made according to the best factor available at the time, and old ones being controlled and corrected by quartz plates standardised according to the latest factor."

It would therefore appear that British chemists are largely in favour of retaining the present international standard, which in fact is now in almost universal use (excepting in France and Mauritius).

CHEMISTRY AT THE INDIAN SCIENCE CONGRESS.

The Eighth Science Congress was held this year from January 31 to February 5, at Calcutta, under the presidency of Sir Rajendranath Mukerjee. About 150 papers were presented.

On February 1, Dr. E. R. Watson, Director of the Cawnpore Research Institute, gave an address on "Chemical Research for the Development of Industries in India." Speaking of the dye industry, he said that the amount of coal tar at present available was quite insufficient, but if more were produced he saw no reason why the industry should not thrive. He was not very hopeful about wood distillation, but white lead, potassium permanganate, and various other chemicals might be made cheaply. The manufacture of sulphuric acid was handicapped by the want of indigenous sources of sulphur. There was some talk of making it from natural sulphates, but it was very doubtful whether this would pay. Industrial alcohol could be prepared from grain. There were three classes of industries possible in India, viz., (1) iron and steel, (2) textiles, and (3) chemicals.

In the discussion that followed, Dr. H. K. Sen, who has had considerable experience in the manufacture of sulphuric acid and sulphates in India, said that unless there were State protection chemical industries could not stand competition from outside. Sulphuric acid of sp. gr. 1·84 was sold in England at 28s. per ton before the war, but it could not be manufactured in India for less than Rs.97.5 per ton (rupee=1s. 4d. at par). Nitric acid would cost 4·5 annas (6¾d. at normal exchange) per lb. Magnesium sulphate used to sell in Germany at Rs.1—8 per cwt., whereas it could not be manufactured in India for less than Rs.4—14 per cwt. Dr. Sen advocated the manufacture of industrial alcohol from calcium carbide, which, according to the calculations of Drs. Simonsen and Sudborough, could be manufactured in India at £6 per ton. He said that 1 ton of carbide would yield as much alcohol as 8 tons of potatoes, viz., 700 kg. Tertiary pyritic shale was mentioned as a possible source of sulphur for the manufacture of sulphuric acid. India produced 6000 tons of saltpetre and exported 4000 tons annually. Nitric acid could be manufactured from it cheaply if the by-product potash salts could be disposed of profitably. Dr. H. E. Watson, of Bangalore, remarked that the manufacture of one or two dyes would not do; either a large number should be made or none at all. He was in favour of manufacturing industrial alcohol from cellulose by a biochemical process. It should stand competition with petrol. Prof. Gilbert Fowler, of Bangalore, expressed the opinion that the proposed manufacture of dyes in India was hopeless; nor was the manufacture of sulphuric acid from gypsum possible in India on a commercial scale on account of the high temperature required. In Europe calcium sulphide and sulphate were waste products in the manufacture of soda, yet no one thought of making sulphuric acid from them. Industrial development must grow side by side with the solution of the food problem, which was of the utmost importance at the present time.

In the Section of Chemistry some two dozen papers on the pure or applied science were read or taken as read. The president, Dr. H. E. Watson, discussed the development of Indian chemical industry in his address. Taking into consideration the vastness of the Indian Empire and the difficulties of railway communication, he was not in favour of erecting large factories in one or two places. Small factories distributed all over the country would be more suitable. He tabulated all the industries, giving figures of merit to each and taking into consideration all the conditions as to raw material, labour, transport, demand, competition, etc. He found that the salt industry took the first place, and tiles and bricks came next. Then followed iron and steel, sugar, oil, cement, essential oils, drugs, milk products, etc. For wood distillation the conditions were unfavourable. Hardening of oil for edible purposes was quite possible. The manufacture of sulphuric acid would succeed if small contact-plants were erected in different parts of India. The soda industry could not stand competition from the Brunner, Mond or Magadi Soda companies. The manufacture of bichromate was possible, as there was a great demand for it in the tanneries. Cyanamide could be produced cheaply, but it would be very difficult to induce the Indian cultivator to use it as a fertiliser.

Messrs. G. J. Fowler and D. L. Sen described an investigation carried out on behalf of the Indian Munitions Board upon the bacteria associated with rice and other cereals, in order to study the sources of infection in starch factories, the consequent loss of starch, and allied questions. The bacillus employed by Weizmann for the manufacture of acetone and butyl alcohol from starch is very resistant and survives the ordinary cooking process, but unpolished rice carries a small quantity of an alkaloid which acts as a selective antiseptic and protects the rice from bacterial attack. Marked differences were observed between the behaviour of polished and unpolished rice even after cooking, and microscopic examination showed that the polished grain carried more organisms of greater variety. Rice can be sterilised by a dry treatment with sulphur dioxide, which, however, also inhibits germination; this is an advantage in the case of grain that is to be used for the manufacture of starch, but, of course, not for seed grain. Weizmann's bacillus can be isolated by making successive sub-cultures from an original unsterilised mash of grain into a sterile mash maintained for one or two minutes at 90° C. A very fair acetone fermentation is obtained after nine sub-cultures, showing that the isolation is a selective process rather than the acquirement of new characteristics by the organism in the course of generations.

Dr. Fowler, in conjunction with Mr. K. C. Srinivasiyer, found that sulphur dioxide was also a good antiseptic for use in the manufacture of glue and gelatin. In this case it must be in aqueous solution, the strength of which should be about N/8, equivalent to about 0·75 gm. of sulphur per kg. of the final product. It also clarifies the material and decolorises it. A paper by G. J. Fowler and B. Bannerji on the utilisation of *megasse* (the residue left after the pressing of sugar cane, now usually used as fuel) described how by hydrolysing it with dilute sulphuric acid under pressure a solution was obtained which, after the addition of some ordinary sugar, can be fermented for the manufacture of power alcohol. After heating under pressure with

caustic soda the residual fibre can be worked up into cheap paper stock.

Another biochemical paper, by G. J. Fowler and M. Srinivasiyer, dealt with the indigo dye vat. Instead of hydrosulphite, the Indians add the seeds of "cassia tora" to reduce the indigo to indigo white. These seeds contain a sulphur protein and bacteria that ferment and produce hydrogen, which effects the change of the indigo. There is also a bitter substance which acts as a selective antiseptic restraining the growth of other bacteria.

RECENT DEVELOPMENTS IN THE ELECTROLYTIC PRODUCTION OF HYDROGEN AND OXYGEN.

A. J. HALE.

Much of the plant employed up to 1913 for generating hydrogen and oxygen by the electrolysis of water was composed of cells which had been designed prior to 1903, and although some improvements in design and efficiency were introduced during the two or three years before the war, the demand of the Allies for these gases was no doubt responsible for much of the activity recently displayed in this branch of industrial chemistry.

The cells on the market today, many of which have been devised during the last six years, may be classified as bell, filter-press, or unit type. Each cell is usually capable of taking 300—600 ampères, and the electrodes are placed near together to diminish electrical resistance. Apart from the filter-press bi-polar type, the tendency has been to develop the construction of flat-diaphragm units of maximum capacity which occupy a minimum of floor-space. These single units possess the advantage over the filter-press type that any cell in need of repair may be cut out of the series without stopping the remainder, whereas in the filter-press cells the whole group must be stopped while the repair is effected.

Bell Cells.—Under this head may be included all non-diaphragm cells, for the predominant idea in this type is to prevent the mixing of oxygen and hydrogen by encasing the electrodes in such a manner that the discharged gases are directed upwards to their respective mains. Sometimes the construction is unnecessarily complex, as in the Vareille cell (Fr. Pat. of 1905) and Tommasini cell (U.S. Pat. of 1912), and others; but the plant of the Hydrogen, Oxygen and Plant Co., based upon Jaubert's patents of 1916, and the Churchill cell (Pat. of M. Geeraerd of 1916) are of simple construction and reasonably efficient. Each of these cells gives over 6 cb. ft. of hydrogen per kw.-hr.; the former has been put down at several French factories, and the latter is used in several English works.

The principle of the Jaubert cell is shown in Fig. 1, taken from the patent specification. The cell consists of a rectangular heat-insulated tank, in which there are five pairs of electrodes connected in parallel. Each electrode is partly covered by a steel bell, and the dimensions of the bells and electrodes are in proportion to the volumes of gases evolved at each, *i.e.*, 2:1; but, as indicated in the diagram, the length of electrode exposed below the bell is inversely as the volume of gas evolved. Each cell is rated to take 300—600 ampères at 2·3—2·5 volts, and the purity of the evolved oxygen is 97·5—98·5 per cent. before passing through the purifiers.

The Churchill unit resembles a filter-press in construction but has no diaphragms. Each electrode plate is so constructed that the oxygen and hydrogen are prevented from mixing when discharged from adjacent electrode faces by vanes of insulating material which guide the gases upwards to their respective channels. Obviously any number of plates may be screwed together to make up a battery. The advantage claimed for this cell is that the absence of an asbestos diaphragm diminishes resistance considerably, so that only 2·0 volts is needed per cell.

Non-diaphragm cells are usually equipped with gas purifiers (consisting of heated platinum spirals) in order to increase the purity of the gases up to 99·5 per cent. or more.

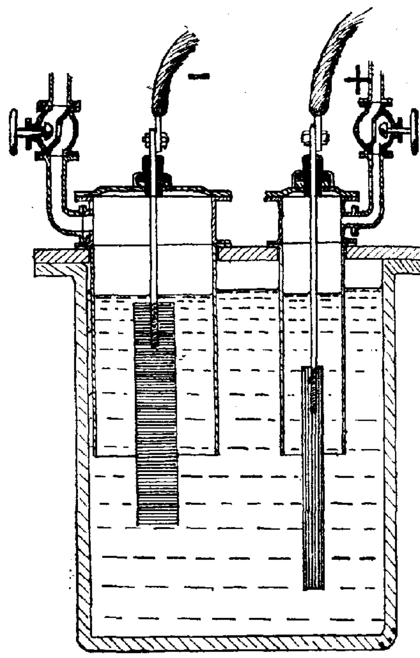

FIG. 1.

Filter-press Cells.—The design of this type is indicated to some extent by its name, and descriptions may be found in text-books on electrochemistry. Several firms have put this type on the market. The National Oxygen Company of Chicago effected improvements in the filter-press design in 1917, and the existence of numerous competitors of the Oerlikon cell (Schmidt's Patents) shows that this type has many points in its favour. Some care is needed in fitting the asbestos diaphragms and in screwing together the plates before starting up, but these are minor handicaps, and such plants have been in use for many years and given entire satisfaction to the users.

Diaphragm Unit Cells, sometimes known as tank cells, have of late been much improved and today represent the most perfect contrivances for producing oxygen and hydrogen by electrolysis. In the early type of cell (1911) manufactured by the International Oxygen Co., an iron tank formed both the containing vessel for a caustic soda electrolyte and the negative electrode. From the lid of this vessel was suspended an iron anode corresponding in shape to the outer tank and separated from it by an asbestos sack which depended from the lid. The kw.-hr. output was 7 cb. ft. of hydrogen of 99·7 per cent. purity.

An improved form of this cell is now made by the Davis-Bournonville Co., New Jersey. The kw.-hr. output is 7·5 cb. ft. of hydrogen, and the dimensions

of a 500-ampère cell are: 13·5 in. × 24 in. × 46 in. in height; 1000-ampère units are: 15 in. × 36 in. × 51 in. in height. A gas purity of 99·5 per cent. is guaranteed, and, in addition, a speciality is made of automatic control throughout the plant which diminishes risk of accident and restricts the amount of supervision required.

The next stage in the development of the unit tank cell was reached almost simultaneously in England and America. A flat cell was designed in which the body consists of a stout steel frame of rectangular shape. On each side of the frame is clamped an iron sheet, one positive and one negative, the two being insulated from each other and separated by an asbestos-sheet diaphragm which divides the cell into two vertical halves, thus effectively preventing the mixing of the oxygen and hydrogen which are evolved when the cell is working. The cell of the Integral Oxygen Co. (Fig. 2) is of this type, and a study of its design and record of output will show that economy of floor-space and material is combined with high efficiency. Each cell covers a floor-space of 4 in. × 42 in., and the total over-all height, with piping, is about 7 ft.

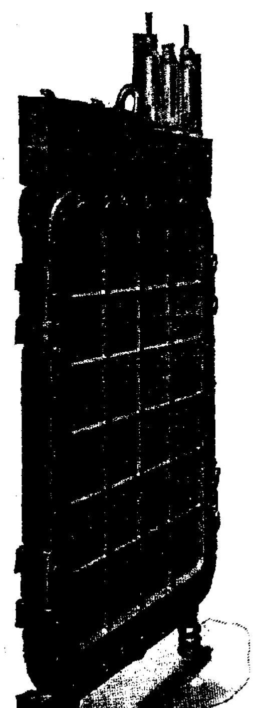

Fig. 2.

On the right side of the body shown is the nickel-plated cast-iron anode, and on the left is a similar iron cathode. The active surface of each plate is corrugated in order to give increased area and to facilitate the circulation of the electrolyte. It has been found necessary to plate the anodes of all electrolysers with nickel in order to avoid the formation of iron-oxide deposit, which speedily interferes with the efficient running of the cell and tends to block the pores of the diaphragm. Cast as parts of the head of this cell are a reservoir for electrolyte, proper channels for collecting the gases, and a simple arrangement of chambers and water-seals acting as an automatic internal-pressure equaliser. At the top of the diagram are shown an eye-bolt for raising and moving the cell, and three glass bells, of which the first is the hydrogen outlet, the second the feed for distilled water, and the third the oxygen outlet. These bells are protected by two iron uprights, the front one being an overflow pipe and the end one a standard, of which the function is entirely protective.

Each cell is rated at 600 ampères and 2·2 volts, and under these conditions gives 9·6 cb. ft. of hydrogen per hour. A battery of 50 cells takes up a floor space of 3 ft. 6 in. × 16 ft. 8 in., and with a current of 800 ampères at 2·4 volts will give 15,360 cb. ft. of hydrogen per 24 hours. The weight of the empty cell is 800 lb., and when filled with electrolyte 1000 lb., so that each holds about 20 gallons of water, one gallon of which will give about 160 cb. ft. of hydrogen.

The Levin cell (U.S. Pat. 1917), made by Electrolabs, Pittsburgh, Pa., is constructed on the same plan and is thoroughly efficient. A complete cell, which has the dimensions 30 in. × 25 in. × 6¼ in., is rated at 250 ampères, and weighs when empty 148 lb.; a larger type, 43 in. × 37 in. × 8¼ in., rated at 600 ampères, weighs 325 lb., and gives 9·6 cb. ft. of hydrogen per hour. There are three compartments, the two outer ones for generating oxygen, and the inner one for hydrogen. The three electrodes are independent of the casing of the cells, so that its construction differs in some respects from that of the cell last described.

Some idea of the efficiency of the various cells may be gained from the figures in the following table, which shows the output of hydrogen per kw.-hr. as well as the voltage needed for each cell and the guaranteed purity of the oxygen and hydrogen evolved:—

Cell.	Voltage required.	Hydrogen per kw.-hr. cb. ft.	Purity of Hydrogen Per cent.	Purity of Oxygen Per cent.
Oerlikon filter-press	2·2–2·4	6·0	99	97
National Oxygen Co., Chicago ..	2·0	7·4	99·5	99·3
Integral Oxygen Co.	2·2	7·3	99·5	99
Levin cell.. ..	2·2	7·3	99·8	99·5
Oxy-hydrogen and Plant Co. ..	2·3	6·0	98	96
Churchill Cell. ..	2·0–2·2	6·5–7·0	99	98
Davis-Bournonville.	2·1	7·5	99·5	99

Cost and Lay-out of Plant.—In considering the cost of purchasing and running plant for producing hydrogen and oxygen, attention must be directed to several factors. Direct current is necessary, and this may involve the installation of generating plant for converting the alternating current supply. The gases will be passed to gas holders under a pressure of a few ounces and thence, by low-pressure compressors, to storage tanks at 300 lb., and, in the event of one or both gases being sold, high-power compressors will be needed, together with steel cylinders for bottling under a pressure of about 2000 lb. per square inch.

The layout of a complete plant would consist of the cell room containing the electrolysers, in close proximity to the generator room, if generators are needed. From here the gases would pass to the gas-holders, of the usual gasometer type, which are erected in a suitable position outside and a few yards away from the cell room, and capable of holding at least 12 hours' supply of gas. In a neighbouring house would be the compressors, one for each gas, and the compressing table for filling the cylinders used in transporting the gas to the ultimate user. If the gases are to be used on the works, low-power compressors should connect to storage tanks holding 1000—5000 cb. ft., from which pipe lines will distribute the gas to the work-benches.

The capital outlay involved may now be considered. The floor-space needed for cells to supply

5000 cb. ft. of hydrogen per 24 hours would be as follows:—

Type.	Floor-space.	Type.	Floor-space.
Integral Oxygen Co.	7'x3' 4"	Churchill.	40'x3'
National Oxygen Co.	13'x4' 6"	Hydrogen Oxygen & Plant Co.	50'x9'

The approximate cost of the electrolysers will be £1400—£1500 in each case, and for compressors, gasholders, etc., another 150 per cent. may be added. Electrolysers for generating 20,000 cb. ft. of hydrogen and 10,000 cb. ft. of oxygen per 24 hours will cost approximately £6000, and if the whole of the accessory plant be needed a total outlay of £15,000 may be involved.

An example showing the total cost of producing oxygen and hydrogen by this method may now be outlined, in which the costs quoted are certainly above the average.

Costs.

Plant to provide 5000 cb. ft. of hydrogen per 24 hours	
Initial outlay on cells, switchboard, generator, compressors and gasholders	£4,000

Annual Cost of Production.

300 days of 24 hours, hydrogen	1 500,000 cb. ft.
" " oxygen	750,000 cb. ft.
Energy per 1000 cb. ft. O_2 / " 2000 cb. ft. H_2 } 300 B.Tr.U. at 1d.	25s. 0d.

Overhead Charges.

5% Interest on £4000	£200
Depreciation at 10%	£400
Attendance, 20 hrs. per day at 2s. per hour	£600
Annual cost of current, at 1d. per unit	£925
	£2125

Cost per 1,000 cb. ft. of oxygen (hydrogen being wasted) .. 56s. 0d.

If however both gases are utilised:—	per 1000 cb. ft.
Cost of oxygen	28s. 0d.
" hydrogen	14s. 0d.

Allowing for 200 cylinders at £5, *i.e.*, £1000, if gases are to be bottled and transported, the sum of £200 would have to be added to overhead charges for interest and depreciation at 20 per cent. In plants for oxy-hydrogen cutting the cost would be lower in labour, whilst low-power compressors only would be needed and no gas bottles, making a difference of £500, approximately, in capital expenditure.

The largest item is cost of current, but there are cases where this is cheap, or even surplus power.

The total in such a case might be £1500 for overhead charges. Hence cost of oxygen=40s. per 1000 cb. ft.; or if shared by hydrogen, 20s. per 1000 cb. ft. for oxygen, 10s. per 1000 cb. ft. for hydrogen. At the present time very many works are using the electrolytic process for generating oxygen and hydrogen, both in Europe and America. Among the uses to which the gases are being put are metal welding and cutting, hydrogenation of oils, manufacture of incandescent filament lamps, metal brazing, oxy-acetylene welding, smelting work, steel production, synthetic ammonia, accumulator works. The various Government aircraft stations are equipped with electrolytic generators, and the uses of the gases are extending rapidly.

Although it is a great advantage to utilise both gases on the spot, this is not always done, and sometimes the hydrogen, or even the oxygen, is run to waste.

An analysis of about 70 plants, put down on one system only, shows 18 works utilising both gases for their own manufactures, and 17 producing both gases exclusively for supplying outside consumers. Twenty are using only the oxygen, and the rest generally combine the use of one gas for their own needs with the sale of the other to outside consumers; but, obviously, on account of its value, oxygen is seldom run to waste.

The plant is comparatively simple in construction, is run with but little supervision, and generates the purest gases. The purity of the gases is sometimes the all-important factor, as in the hydrogenation of oils and in oxy-hydrogen cutting.

There can be no doubt that the electrolytic production of oxygen and hydrogen has a considerable future before it.

MEETINGS OF OTHER SOCIETIES.

ROYAL PHOTOGRAPHIC SOCIETY.

At the annual meeting of the Society held on March 8, Dr. G. H. Rodman was elected president for a second year, Sir William Pope and Mr. W. L. F. Wastell were elected vice-presidents, and most of the members of the old council were reappointed. The report of the year's work showed an exceptionally large accession to the membership. This will afford considerable financial relief to the Society, whose expenses naturally reflect the changed conditions produced by the war; the subscription is being raised only to those members joining after 1920. The Society's Progress Medal was presented to Mr. F. F. Renwick "in recognition of his researches in the chemistry and physics of photography." Previous recipients of the medal include Abney, Hurter and Driffield, and the Lumières.

The meeting of the Scientific and Technical Group, held on March 15, was devoted to reflex cameras. Mr. Newman gave a short sketch of the history of this form of camera, including a statement of the most important mechanical requirements and the usual methods of meeting them. Major A. Abrahams described the use of the camera in high-speed photography, especially of rapidly moving objects.

SOCIETY OF GLASS TECHNOLOGY.

During the forenoon of the meeting held in Newcastle-on-Tyne on March 16, a visit was paid to the works of Messrs. Lemington Glassworks, Ltd., Lemington-on-Tyne, to see the manufacture of electric-lamp bulbs and glass-tubing. Of especial interest were the Westlake automatic machines, which turn out bulbs at the rate of 1000 per hour.

The first paper at the afternoon meeting was a "Note on the Corrosion of Fireclay Refractory Materials by Glass-making Materials," by Mr. D. Turner and Prof. W. E. S. Turner. The authors found that even at 800° C. soda ash attacked fully-burnt fireclay, and that particles of a certain size lost 11 to 18 per cent. of their weight within three hours. Salt cake was not nearly so active as soda ash, as it took up only 1 per cent. of the fireclay at 800° C. The results indicated a direct correlation between the corrosive action of alkali salts and their temperature of decomposition, those decomposing at the lowest temperatures, *e.g.*, nitrates, being the most corrosive.

In a paper on "The Clouding of Glass," Dr. M. W. Travers described a research undertaken to determine the causes of the clouding of soft soda-glass during lamp-working operations at a short distance from the hottest zone. As no clouding effect was observed when pure hydrogen and air were used, he concluded that clouding was associated with some impurity in the gas, and further experiments showed that sulphur dioxide was the chief cause. The remedy lay in purifying the gas from sulphur, as was practised by the South Metropolitan Gas Co. Mr. W. W. Warren drew attention to the difficulty caused by the presence of sulphur in

the working-pot of the Westlake machine, and Mr. F. F. S. Bryson stated that the Glass Research Association had been considering the same problem.

A paper by Miss E. M. Firth and Prof. Turner on "The Shrinkage, Porosity, and Density of British Fireclays after Firing at 1500° C." was postponed owing to lack of time.

Prior to the reading of the papers the chairman, Dr. Travers, referred to the death of Lord Moulton, and it was unanimously resolved to record in the minutes the Society's appreciation of the great services he had rendered to science.

THE FARADAY SOCIETY.

A meeting of the Faraday Society was held in the rooms of the Chemical Society at Burlington House on March 22, when Prof. A. W. Porter delivered his presidential address on "The Scientific Work of the late Lord Rayleigh."

Lord Rayleigh was the first vice-president of the Faraday Society, and but for ill-health he would have been its president. His interests in physics were very wide, and the recently published collection of his researches contains more than four hundred papers. He was equally distinguished as a theorist and as an experimentalist, and though some of his experimental work necessitated most elaborate apparatus requiring consummate skill for its design and use, he always took the keenest delight in the design of the simplest apparatus with which most valuable results could be obtained. Considering some of Lord Rayleigh's elaborate experimental work, Prof. Porter pointed out that, although at the beginning of his work the absolute value of the ohm was only known to within 4 per cent., his classical determination gave a value differing by only 1 part in 10,000 from the most recently determined figure. Similarly, he determined with certainty the fourth figure of the electrochemical equivalent of silver, although the previous work had left an uncertainty of 2 per cent. Another example of this type of work was the famous discovery of argon.

Turning to the simpler experimental methods, Prof. Porter mentioned the simplification introduced into interferometry by abolishing the necessity for an accurate parallel movement between two plates. Another interesting observation was that the fouled surface of a liquid may be cleaned sufficiently for conducting surface-tension measurements by the simple expedient of scraping it with a piece of paper or with an expanding ring.

Referring to Lord Rayleigh's interest, from 1871 onwards, in the problem of the colour of the sky, the speaker foreshadowed useful developments of his work which he hoped would soon be published by Captain Paris. Lord Rayleigh also explained the cause of the gorgeous colours often to be seen in crystals of potassium chlorate, and the arguments he adduced are applicable to the reflection of X-rays by crystals.

In his work on capillarity and the intrinsic pressure in liquids, Lord Rayleigh did not consider very deeply the theoretical aspects of the phenomena or make much advance on the ideas of Laplace. Prof. Porter then showed that if the assumption be made that the force of attraction between two atoms, whose centres are at a distance of r from each other, varies inversely as r^n, and if it be assumed that the value of r can never become less than a fixed quantity σ, then measurements both of surface tensions and of intrinsic pressures show that n must be about 8·3. It was, however, necessary to point out that it is improbable that the centre of the atom can be regarded as the centre of the attraction.

Lord Rayleigh was always keenly interested in hydrodynamics and made extensive use of the method of dimensions, a particular case of which is known as "the principle of dynamical similarity." When this is applied to the sand-blasting of glass, it is readily seen that, on the assumption that rupture occurs when a particular stress is exceeded, independently of its duration, the rupture of the glass depends on the velocity of a particle of sand, and not on its size.

Mr. S. Field read a comprehensive paper on "The Electrolytic Recovery of Zinc," in which he described the state of the zinc industry both at home and abroad, and discussed the relative merits of the electrolytic and distillation processes. A detailed account of the electrolytic process followed, together with figures of working costs. The author believes that the employment of electrolytic extraction, by rendering possible the use of low-grade ores, might ameliorate the present depressed state of the industry in Great Britain and increase the national wealth. Mr. W. E. Hughes presented the first part of a paper on "The Forms of Electro-deposited Iron and the Effect of Acid upon its Structure," which dealt only with deposits from a bath composed of ferrous and calcium chlorides. The author showed that the structures found in iron deposits formed in such a bath are varieties of two general and distinct types —the normal and the fibrous—the latter being characteristic of deposits formed in acid or in agitated solutions. It was further shown that macroscopic features correspond with a macroscopic structure, a fact which may be used to facilitate control of the process. The last paper, by Prof. Alex. Findlay and Mr. V. H. Williams, was entitled "Notes on the Electrolytic Reduction of Glucose." Negative results were obtained in an attempt to obtain by electrolysis the hexahydric alcohol corresponding with glucose; both with graphite and with lead electrodes, glucose is reduced to formic acid and a pentose.

SOCIETY OF PUBLIC ANALYSTS.

A meeting was held in the Chemical Society's Rooms on April 6, Mr. A. Smetham presiding.

In a paper on the "Estimation of Strychnine in Scale Preparations containing Quinine and other Cinchona Alkaloids," Messrs. T. F. Harvey and S. Back discussed existing methods for separating strychnine and quinine which are only of limited value. The method recommended by the authors is based on the tartrate method of Harrison and Gair and on the ferrocyanide method of Simmonds. The greater part of the quinine is directly precipitated as tartrate from an aqueous solution of the scales, the strychnine and residual quinine are extracted from an aliquot part of the filtrate, and the strychnine is then precipitated as ferrocyanide. Characteristic residues are usually obtained. With the exception of quinicine, the behaviour of which was described, the presence of small quantities of other cinchona alkaloids is not detrimental.

Mr. J. L. Lizuis described "A Method for the Determination of the Acidity of Coloured Solutions," which consists in approximately neutralising the solution, filtering through a paper previously treated with the indicator solution, adding small quantities of standard alkali or acid, and refiltering, the procedure being continued until the filter paper gives the permanent coloration of the indicator.

"The Action of Water on Lead" was dealt with by Dr. J. C. Thresh, who referred to the conflicting views held on this action. He has found that water free from dissolved oxygen has no action on lead, but if free oxygen be present, action begins forthwith and continues until all the oxygen is used up, the rate of action depending on the amount of oxygen present. Theoretical explanations of the reactions involved were given.

A paper on "A Colour Reaction for Aconite" was read by Dr. S. Mellaneh, who stated that the colour reactions at present known for aconite were really those of benzoic acid, and that colour reactions generally were seldom useful unless applied to pure alkaloids. The author has devised a very delicate test for aconite, involving the use of potassium ferrocyanide and formic acid. The method is apparently specific, but confirmation is being sought; it is applicable not only to the pure alkaloid, but also to the powdered root, and the author recommends it for medico-legal work, particularly in India.

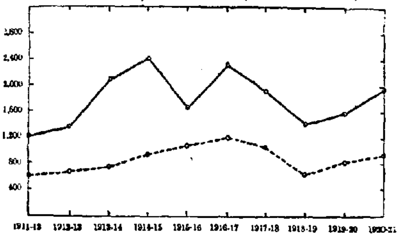
NEWS AND NOTES.

BRITISH INDIA.

The Groundnut Crop of 1920-21.—The final general memorandum on the groundnut crop of the season 1920–21 states that the total yield is estimated at 931,000 tons of nuts in shell, as against 822,000 t. last year, or an increase of 13 per cent. The total area returned is 1,951,000 acres, as compared with 1,586,000 in 1920, or an increase of 23 per cent. Of the total area under this crop in British India, 75 per cent. is in Madras, 13·5 per cent. in Burma and 10·5 per cent. in Bombay.

Area and Yield of Groundnuts, 1911–12 to 1920–21.

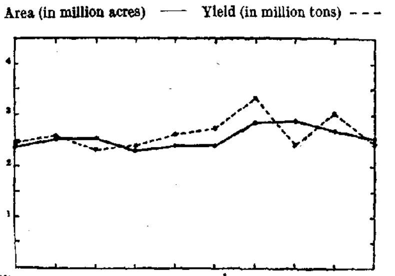
Area (in thousand acres) —— Yield (in thousand tons) - - -



The Sugar-Cane Crop of 1920-21.—The area sown to sugar-cane is estimated at 2,553,000 acres, or 5 per cent. less than a year ago, when it was 2,686,000 acres. The estimated yield of raw sugar (*gúr*) is 2,465,000 tons, compared with 3,036,000 t. last year, or a decrease of 19 per cent. Owing to deficient rainfall in certain of the producing provinces, the season has not been favourable, on the whole, for the crop sowing. The chief contributors to the total yield are:—United Provinces 52·4 per cent., Punjab 16·5 per cent., Bihar and Orissa 10·5 per cent., Bengal 8·7 per cent. and Madras 4·2 per cent. The appended chart illustrates the estimates of area and yield, as compared with the final figures for the preceding nine years.

Area and Yield of Raw Sugar, 1911–12 to 1920–21.

Area (in million acres) —— Yield (in million tons) - - -



—(*Indian Tr. J., Feb.* 25, 1921.)

Cinchona and other Medicinal Plants.—The vital need of possessing within the Empire essential raw materials, such as quinine, was strikingly brought home to us during the war. In 1914 Germany, one of the most important manufacturing and distributing countries, had full stocks in hand, with facilities for securing (during the early stages of the war) enough of the raw product to meet the wants of herself and her partner-in-arms. On the other hand, the supplies of the Allies were none too plentiful, and from the first they were dependent on the goodwill of Holland, which had, and still has, the virtual monopoly in her Java cinchona plantations. The Dutch, however, needed coal, machinery, and rice from Burma, so the result was a collective bargaining by the Allies and the signing of an agreement for the supply and distribution of quinine by the Dutch Quinine Combine and the Association of Quinine Manufacturers in Allied countries. This agreement was faithfully kept—although at some pecuniary sacrifice to the Dutch—until the end of the war. After the armistice the short supply of quinine led to hectic speculation by holders in second and third hands, and Government control became impossible. After decontrol prices became more stable, and at the present time the British Quinine Corporation, working in conjunction with the Dutch Combine, practically controls the British quinine market. Although prices have declined as a result of decontrol, the production of bark and quinine as a lucrative commercial proposition is apparently more firmly established than ever before. There is, therefore, a growing interest in cinchona cultivation in America, Japan, and within the British Empire.

An important scheme for developing the production of quinine in India was initiated during the past year, of which an account is given in the report on the Government Cinchona Plantations and Factory in Bengal for 1919–20, published in the *Calcutta Gazette* of December 8, 1920. According to this report it is probable that Burma will in time become an important source of the drug for India or the Empire. Owing to the strain of the war period, cinchona crops in Bengal have been much reduced. In 1919–20 the yield was 513,043 lb., and a still smaller harvest is anticipated for 1920–21; but this is all to the good of the plantations. The total area under cinchona is 3080 acres, of which 2319 acres is comparatively young. There are approximately 3,610,000 cinchona trees on Munsong estate and 1,480,000 on Mungpoo, making a total of 5,090,000. During the year under review 149,835 lb. of Mungpoo bark and 334,410 lb. of Munsong bark were worked up, besides 514,540 lb. of bark obtained from Java for the Government of India. These showed on analysis a total of 20,588 lb. quinine sulphate on the Bengal grown bark and 31,571 lb. on the imported bark. The products actually obtained were 47,724·25 lb. of quinine sulphate, 1022 lb. of hydrochloride (equivalent to 1160 lb. of sulphate), and 15,166 lb. of cinchona febrifuge (containing quinine equivalent to 2226 lb. of sulphate), making in all an average yield of 98 per cent. on analytical results. The total cost of the total harvest was Rs. 97,497, but the actual market value was Rs. 2,74,670; and it is pointed out that the purchase of the same quantity of bark in the market would have cost the Government Rs. 1,77,174 (*plus* freightage and carriage charges) more than it actually did.

Ipecacuanha, digitalis, and belladonna are being grown experimentally in Burma. Of the first-named, 76,000 plants are being cultivated, and during the past year the older plants seeded well and all the seed has been sown. It is still uncertain if the cultivation of ipecacuanha can be made to pay. The digitalis crops at Mungpoo did very well until heavy hail storms destroyed 50 per cent. of the leaf. To obviate this havoc in future, a portion

of the 1920–21 crop will be planted in partially-cleared forest only. European methods of drying the leaf have been employed successfully, and the product is of high quality. Moreover, with digitalis at its present price the requirements of India could easily be met by home-grown supplies. The cultivation of belladonna is only in its infancy, and good results are expected, but chenopodium culture has been discontinued owing to the low yield of oil. The collection of lycopodium from the natural supply on Mungpoo has also ceased as there is apparently no demand.

Department of Industries.—A Board of Industries and Munitions was constituted in February, 1920, as a temporary organisation to close the war commitments of the Indian Munitions Board, to take over some of the work of the Commerce and Industries Department and the Public Works Department, and to start the organisation of the new Department of Industries. This it has done, and consequently the board was merged into the new Department by a resolution of the Government of India dated February 15, 1921. The new department is under the charge of the Hon. Sir Thomas Holland, who is a member of the Governor-General's Executive Council.

The Development of the Indigo Industry in Assam in conjunction with Tea and other Crops is the title of Indigo Publication No. 8, of the Agricultural Research Institute, Pusa, written by Mr. W. A. Davis, Indigo Research Chemist to the Government of India.

Java indigo grows more luxuriantly in Assam than in Bihar, the yield of unusually high-quality green plant and seed per acre being extraordinarily high. Bihar has been almost entirely dependent on the United Provinces and Assam for its supply of indigo seed since the war. A small indigo factory was installed on the estate of the Panchnoi Tea Co. in 1919, and the yield of plant per acre, the leaf percentage on the weight of the plant, and the indigotin content have proved unusually high. In Bihar the bacterial-steeping conditions are usually good and give rise to a 70 per cent. efficiency of extraction, but in Assam the yield and quality of the indigo at first obtained were so poor, owing to the difficulties caused by green vats and bad settling, that the enterprise appeared likely to prove a failure. These difficulties have been traced to the fact that the water used for steeping at Panchnoi was obtained from a small river rising in the hills only a few miles away. The bacterial character of this water changed very rapidly with variations of rainfall in the hills; the water was very soft and, as a rule, was extraordinarily deficient in the indican-hydrolysing types of bacteria which are essential for good steeping results. An increase in the duration of steeping at Panchnoi gave much better results, the difficulty of green vats and bad settling disappeared entirely, and a very high yield of greatly improved quality was obtained. It is of the greatest importance to ascertain at each factory in Assam the duration of steeping each day which gives rise to the maximum produce and quality, and a simple colorimetric test has been devised for this purpose which permits the production in Assam of high-quality indigo, well up to the Bihar standard.

The profits to be derived from growing indigo in Assam are considerable, and with favourable working the product could not only compete with synthetic indigo, but displace it completely from the market. In addition the great value of the seet, or refuse from the steeping vats, as a rapid-acting nitrogenous manure for promoting the leaf-growth of other crops must be taken into account. The growth of indigo in Bihar is so poor that the seet obtained from 4—5 acres of indigo land only suffices to manure 1 acre of land, whereas in Assam, owing to the luxuriant growth of indigo, the seet from 1 acre would be sufficient to manure 1 acre of land. Indigo could be grown with great advantage on newly-opened or newly-cleared tea-land, and would enable considerable profits to be made in the preliminary 4—5 years before the tea bears. Seet has also proved an admirable manure for sugar-cane, the growth of which in Assam is likely to develop considerably in the future, and indigo could be grown with particular advantage on newly-opened sugar estates. The growth of flax in conjunction with indigo in Assam is also worthy of consideration, for the flax could be grown and manufactured in the cold weather, the indigo vats would be suitable for retting, and this crop would utilise labour advantageously in the off-season. In China and Japan there is an immediate and considerable market waiting to be supplied with indigo in the proper form, *i.e.*, a stable 20 per cent. paste such as can now be prepared readily. It is of the greatest importance that the output of natural indigo from India should be increased as rapidly as possible, for the present annual output from Bihar is less than 5 per cent. of the requirements of China and Japan.

FRANCE.

Organisation of Chemical Societies.—At the last general meeting of the Société de Chimie Industrielle, M. Paul Kestner, president, reviewed the work of the Society, put forward certain proposed modifications in its constitution, and explained its relationship to other French chemical organisations. The modifications include the formation of groups or sections corresponding to the various branches of applied chemistry; each group will appoint a president, vice-president, and secretary to hold office for three years, who will report monthly to a full meeting of all members of the group; and there will be a general meeting of all the groups once a year. The proposal to publish a joint abstract journal for pure and applied chemistry has been abandoned, and it has been agreed that the State subsidy granted for this purpose shall be shared by the *Bulletin de la Société Chimique* and *Chimie et Industrie*, which will publish abstracts in pure and applied chemistry, respectively.

The three chief chemical organisations in France are:—(1) Le Comité National de Chimie, which co-ordinates research work in pure and applied chemistry with a view to assisting Le Comité National des Recherches. (2) La Fédération Nationale des Associations de Chimie, founded in 1919 to co-ordinate the scientific, technical and economic activities of the following seven societies: La Société Chimique de France, La Société de Chimie Industrielle, L'Association des Chimistes de Sucrerie et de Distillerie, La Société des Experts Chimistes, La Société de Chimie physique, La Société de Chimie biologique, and L'Association des Chimistes de l'Industrie textile. (3) L'Union Internationale de la Chimie Pure et Appliquée, also founded in 1919, and L'Office Internationale de Chimie, the functions of which were detailed in our issue of July 31, 1920 (p. 251 R).

Industrial Notes.—*Chemical Industry.*—Except for a more active inquiry for superphosphate, market conditions remain practically unchanged. The factories have reduced their production by 40—50 per cent. The Lyons Fair was again a great success, and it is reported that most probably Lyons will become the centre of all fairs in France, and thus take the place of Paris, where in future a yearly exhibition of artistic products will be held. Lyons will be to France what Leipzig is to Germany.

Metallurgy.—The production of cast iron in France during 1920 was 3,317,371 metric tons, of

which 1,355,000 t. came from the recovered province of Lorraine; this compares with 5,311,316 t. in 1913 (exclusive of Lorraine). Of steel, 2,961,508 t. was produced, including 1,098,000 t. from Lorraine, against 4,635,166 t. in 1913. Although inquiries are more numerous the metallurgical market shows no decided improvement, and prices remain uncertain as no decision has yet been reached concerning the price of metallurgical coke.

Cotton Cultivation.—The cultivation of cotton is progressing very well in the French colonies; Algeria, in particular, is making good headway and will soon have about 2700 acres under cultivation. Great efforts are being made in Désirade Island, near Guadeloupe, as well as in French West Africa, in Togo, and in Cilicia.

The Window Glass Industry.—Owing mainly to the German invasion of Northern France the French production of window glass fell 75 to 80 per cent. during the war. Consequently imports of window glass, largely from the United States, increased very greatly, viz., from 3640 metric tons in 1913 to 8142 in 1915, 8612 in 1917, 47,900 in 1919, and 34,169 in the first nine months of 1920. The exports fell from 6116 t. in 1913 to 830 t. in 1915, and 525 in 1919, but increased to 3800 t. in the first nine months of 1920. During the war two new window-glass factories were established in the interior of France—the Société des Verreries Mesmer, at Andrezieux (Loire), and the Société des Verreries du Centre, at Montluçon (Allier). Practically all the factories in the devastated regions have been reconstructed, and the French production of window glass is now much in excess of home requirements. Exporters find it difficult to make firm quotations owing to unstable coal prices and unsettled labour conditions. In December last several factories in the north had to close down owing to lack of orders and dear coal. Large stocks are accumulating, and the Government is being urged to fix a special low price for coal used by glass manufacturers, in order to assist them in competing with their Belgian rivals.—(*U.S. Com. Rep., Jan.* 26, 1921.)

CANADA.

Maple Sugar, Honey, and Wax in Quebec.—The production of maple sugar in Quebec in 1920 amounted to 13,393 long tons, of an estimated value of $7,000,000. Apiculture is also a flourishing industry, and the output of honey and wax was 1313 t. and 12 t., respectively.—(*Official.*)

Mining Developments in Vancouver Island.—The Canadian Pacific Railway Co. is about to undertake a survey of two million acres of mineral-bearing land owned by it in Vancouver Island, the work to be carried out under the direction of the Trail Smelter Co., also owned by the C.P.R. It is considered probable that the survey may lead to the erection of a smelter on Vancouver Island. Particular attention will be given to the development of the coal deposits.— (*Official.*)

Proposed Asbestos Control in Quebec.—The Quebec Government is reported to be considering the question of controlling the asbestos industry of the province in the same way as the pulp-wood industry, *i.e.*, by attaching to mining leases a condition that the mineral won shall be worked up, either wholly or partially, in factories erected in the province. Quebec provides 85 per cent. of the world's supply of asbestos. In 1919–20, 174,521 tons, valued at $11,758,234, was exported; but very little is manufactured in the province.—(*Official.*)

Coal Production in 1920.—The Canadian Bureau of Statistics reports that the output of coal in 1920 was 16,968,568 short tons, the highest production ever attained; in 1919 it was 13,919,096 t. Alberta produced 41 per cent. of the output, Nova Scotia 37·8, British Columbia 18·3, Saskatchewan 1·9, and New Brunswick 1 per cent. By kinds of coal, the increases in output amounted to 0·3 per cent. for anthracite, 16·0 per cent. for bituminous, and 5·6 per cent. for lignite. In December, 1920, 22,848 underground and 8508 surface workers were employed at the mines. Exports increased to 2,558,223 t., compared with 2,070,050 t. in 1919, Nova Scotia being the chief coal-exporting province. Imports from the United States rose from 16,982,773 to 20,815,596 t., Ontario being the largest importer. The total coal supply amounted to 35,225,941 tons.

SOUTH AFRICA.

Output of Base Minerals in 1920.—Returns prepared by the Government Mining Engineer give the output of base minerals in South Africa for 1920 as follows:—

	Output. Tons.	Value. £
Arsenic, white	11	655
Iron ore	2,564	811
Lead ore	587	5,787
Manganese ore	67	277
Zinc ore and concentrates	2,349	15,614
Asbestos	7,112	114,195
Corundum	260	1,446
Graphite	73	2,339
Iron pyrites	3,469	5,014
Magnesite	1,418	3,780
Mica	0.77	500
Ochres, etc.	536	1,049
Talc	682	2,227

The total value of the output was £153,694.—(*S. Afr. J. Ind., Feb.*, 1921.)

AUSTRALIA.

Queensland.

State Enterprises.—The Government of Queensland has undertaken a considerable number of enterprises, under the direction of a Minister for State Industries, which include, among others, pastoral stations, sawmills, coal mines, iron and steel works, canneries, and a produce agency. Last year's balance-sheets for the whole of the enterprises showed assets valued at £1,976,090 and liabilities £1,743,124. The State pastoral stations cover almost 30,728 sq. miles of territory; the coal mines and the steel works are yet in the development stage; and much attention is being given to the development of the cannery industry, which will utilise fruits from the new settlements for returned soldiers formed by the Repatriation Department. The State Forestry Department is also making steady progress, and the director is urging the development of the Forest Products Laboratory. Among the products of the Queensland forests are: —Eucalyptus kinos containing 70 per cent. tannic acid; Cupanias containing commercial saponins; the Bauhinias yield gum arabic; the citron-scented Ti trees produce important essential oils; the Alstonias yield a caoutchouc; the Macrozamias a useful starch and a vegetable wool; and the Grass tree a valuable resin. In addition, there are millions of acres of apparently useless wood which could be distilled for wood spirit, acetic acid, etc.

The Prickly Pear.—This terrible pest is spreading very rapidly over large districts in Queensland, and so far no satisfactory means of eradicating it has been evolved. The following are some of the methods which have been tried experimentally:—(1) The insect *Dactylopius tomtentosus* will under certain circumstances attack the pear and destroy it, but quantities of the insects sufficient for large-scale work have not been obtained. (2) Felling the trees by cheap indentured labour. (3) When properly applied, arsenious chloride gas kills the tree completely, but it is difficult to prevent it rising too quickly. (4) Applying the sun's heat by means of powerful lenses. This method has been tried in California but it is expensive. (5) Sub-

mersion under water for three weeks is quite effective. It has been proposed to dam certain rivers, flood the districts for a time, and to use the water afterwards for irrigation purposes. (6) The Director of Forests proposes to master the growth of prickly pear by means of an overgrowth of drought-resisting, umbrageous, leaf-littering trees such as the southern silky oak, camphor laurel, and Canary Island or other pines (*cf.* J., 1919, 455 R).

UNITED STATES.

Vitreous Enamelling.—A valuable bibliography on the vitreous enamelling of iron and steel has been prepared by Dr. C. J. West and printed in the *Journal* of the American Ceramic Society. As the previous list, by J. C. Branner, covered the literature up to 1906, the present one begins with the year 1907.

Visit of Madame Curie.—Madame Curie is about to visit America, and it is proposed by certain women's organisations to present her with one gram of radium, estimated to cost \$100,000. Although Madame Curie played a leading part in the discovery of this element, she does not possess any of it to-day, and the object of the gift is to enable her to continue her researches.

Food Research Institute.—A food research institute is to be established at Stanford University, California, by the Carnegie Corporation of New York. Dr. C. L. Alsberg, chief of the Bureau of Chemistry of the United States Department of Agriculture, has been appointed director, and the Corporation will provide \$700,000 for the support of the Institute for 10 years. Work will be started on July 1. The University laboratories will be utilised, and duplication of any other work in the field of nutrition will be avoided.

GENERAL.

"Antimony 1913—1919," issued by the Imperial Mineral Resources Bureau as a 34-page pamphlet, describes the chief antimony minerals and their occurrence within the British Empire and in foreign countries, and gives such statistics of production as are available. Antimony is chiefly used in the manufacture of alloys and except in times of war, when large quantities of shrapnel bullets containing about 12 per cent. are required, there does not appear to be a greatly increasing demand. Of the compounds, the tetroxide is used in the ceramic industry for making opaque white enamel, the trioxide (known as antimony white) is used as a pigment, whilst other pigments are antimony vermilion (a red trisulphide of antimony), antimony yellow, produced by the slow oxidation of the sulphide, and antimony blue, resulting from admixture of the above with other minerals. Antimony sulphide is used extensively in the manufacture of rubber goods.

The chief antimony-producing countries in order of importance are China, France, Mexico, Italy, and Australia, but China has long since predominated, and during the war the output of crude regulus and refined antimony greatly increased—from about 13,000 tons in 1913 to about 35,000 tons in 1917. A considerable proportion of the world's output of refined antimony is produced in England from imported raw material. Its high quality is recognised throughout the world.

National Association of Industrial Chemists.—The report of the General Secretary presented at the fourth annual meeting held at Sheffield, Mr. A. B. Searle presiding, states that the Association has successfully come through the recent very critical period caused by industrial depression, and that it now possesses nearly 1100 members. Owing to the need for economy, it has been decided to postpone the publication of a magazine. Members have taken full advantage of the Advice Bureau; a special committee was appointed early last year to draw up a scale of minimum salaries, and as a result of assistance given by the Association over one hundred members who were receiving less than the adopted minimum succeeded in obtaining increases in salary. Another committee was formed to discuss preliminaries with the British Association of Chemists with a view to amalgamation, and negotiations are still proceeding. It is held to be essential to the interests of all British industrial chemists that a single, strong, fully representative organisation should be formed. The Employment Bureau has assisted members in obtaining situations, and only nine are now out of work.

Output of Iron and Steel in the United Kingdom in 1920.—The output of pig iron in 1920 was 8,000,700 tons, an amount which, though 8 per cent. more than the 1919 output—7,398,000 t.—is less than that of any war year and over 20 per cent. less than in 1913. A total of 9,055,600 t. of steel ingots and castings was produced, compared with 7,894,000 t. in the previous year. Production in both cases would have been considerably higher but for the coal strike, which reduced the monthly average during the last quarter of the year. In 1913, a record year, the production of pig iron and steel was 10,260,000 and 7,663,900 t., respectively, and the present proportions of the output indicate that the steel capacity is far in excess of the pig-iron production. The output of metallurgical coke in 1920 was 12,494,400 t., or 1,000,000 t. more than in 1919.—(*Iron and Coal Tr. Rev., Jan.* 7, 14, *Mar.* 25, 1921.)

The Austrian Cement Industry.—The output of the Austrian cement industry for 1920 is estimated at 120,000 to 130,000 tons. Owing to more plentiful supplies of fuel, the production has been increased by 27 per cent., but it is still far below the capacity of the industry and supplies only about 22 per cent. of the normal consumption.—(*U.S. Com. Rep., Jan.* 20, 1921.)

The German Cement Industry.—Government operation of the German cement industry was provisionally abolished in July, 1920, owing to the pressing demand for cement having been satisfied, but the Government still fixes prices for the domestic market. The price of cement increased from 35 to 333 marks per metric ton between August, 1914, and August, 1920, and in December, 1920, it was fixed at 310—333 mk., according to district, lower prices being fixed for cement supplied on Government contracts. During the middle of 1920 cement production increased, partly owing to the resumption of operations of the Offenbach Portland cement works, after a stoppage of over five years. Shortage of coal has affected the cement industry less than other industries, as it has been able to use much low-grade coal. Export of cement has been resumed.—(*U.S. Com. Rep., Mar.* 10, 1921.)

The Mineral Colour Industry in Spain.—A good grade of white lead has been manufactured for many years by the Real Cia. Asturiana de Minas, of Barcelona, a company which owns several large works and can supply most of the Spanish requirements. A small amount of good white lead is also made by the Vincente Fité y Cia at Mataró. Lithopone is made in large quantities principally by the Industriae Quimicas Albinana Argemi company, of Barcelona, which produces a very fine product. The prices of white lead and lithopone are fixed by the Spanish firms so that they are always somewhat lower than those of the imported products. Blanc fixe is made by a number of small firms: the firm of M. and G. Forst, of Barcelona, produces it as a by-product in the manufacture of

hydrogen peroxide. As the blanc fixe made in Spain is not of the best quality, the paper factories import it from England, France, and Germany. Chrome yellow of various shades is made in a large number of small works which also produce chrome green by blending the yellow with imported Prussian blue. Chrome yellow, zinc white, zinc yellow, zinc green, etc., are made at Barcelona by the Fabricacion General Espanola de Colores, Gorardo Collardin; red lead and litharge are made in large quantities and at competitive prices by the Real Cia. Asturiana de Minas, the Vicente Fité y Cia., and by a few other small firms in Catalonia.—(*Z. angew. Chem.*, *Feb.* 4, 1921.)

The Swiss Dye Industry in 1920.—Large quantities of dyes and intermediates were exported from Switzerland during the early part of the year and the manufacture of intermediates not hitherto made proved to be very profitable. The high value of Swiss currency, however, hindered trade with certain countries and made it impossible with others. Nevertheless the situation remained satisfactory until the autumn, when the crisis in the textile industry led to a reduced consumption of dyes; by the end of the year the stagnation had become general. The labour situation was good and there were no strikes for increased pay; wages, however, were raised twice during the year. In gauging the future of this industry, it must be remembered that wages are many times greater than those paid in competing countries, and that coal is many times dearer. In view of the contingencies that foreign import duties may be raised, or that economic conditions in Switzerland may affect the export trade, the controlling dye interests in Basle have purchased a factory in the United States at Cincinnati, in addition to the works acquired in England in 1919.—(*Z. angew. Chem.*, *Feb.* 18, 1921.)

Coquito Nuts in Mexico.—The coquito palm grows abundantly in Mexico in the States of Colima, Jalisco, Nayarit, and Sinaloa, where about 5000 tons of nuts are annually harvested. The oil expressed from the nuts is highly prized by the soap manufacturers of Guadalajaia and Mexico, who consume the entire production. Ten years ago when the value of the nuts was little appreciated, they were sold at about $40 per ton, but to-day they fetch $150—250.—(*U.S. Com. Rep.*, *Feb.* 5, 1921.)

Alcohol Production in the Dutch East Indies.—The export of alcohol from the Dutch East Indies in 1919 amounted to 3,397,680 galls., and in the first half of 1920 to 1,827,100 galls., which compares with 2,685,980 galls. in the corresponding period of 1919. The advance in the trade, which is rapidly assuming greater importance, was mainly due to increased exports to Italy and France, and to a very large demand from Singapore, Hongkong, India, and Ceylon.—(*U.S. Com. Rep.*, *Jan.* 19, 1921.)

Cultivation of the Oil Palm in the Dutch East Indies.—Of late years an increasing interest has been taken in the cultivation of the oil palm (*Elæis Guineensis*) in Dutch East India. Throughout the cultivated area of the east coast of Sumatra considerable tracts of land have been planted with this tree, and in 1919 existing estates were extended and new ones opened. At the end of that year 42 estates, covering an area of 13,500 acres, were devoted exclusively to this particular palm, and the total production of palm oil amounted to 830 metric tons, as against 330 tons in 1918. It is expected that during the next few years the area under cultivation will be considerably extended, and if the planting schemes now in hand are fully realised, the cultivated area should eventually yield a production of about 100,000 tons of palm oil.—(*Dutch East Indian Archipelago*, *Jan.* 25, 1921.)

PERSONALIA.

Prof. L. J. Henderson has been appointed Harvard exchange professor in biological chemistry to France, and will lecture at the Sorbonne during the second half of the present academic year.

Recent appointments in the University of New York include those of Prof. H. R. Moody as professor of chemical engineering, and Prof. W. L. Prager as ordinary professor in the same faculty.

Mr. H. Salt, late of Leeds University, and now of the Forest Products Laboratory of Western Australia, is making a survey of the resources of tanning materials in that State on behalf of the local Government.

Dr. R. F. Ruttan, head of the chemistry department at McGill University, has succeeded Dr. D. G. MacCullum as administrative chairman of the Advisory Council for Scientific and Industrial Research in Canada.

Prof. K. Hess has accepted the post of director of the organic-chemistry section of the Kaiser Wilhelm Institute for Chemistry in Berlin, in succession to Prof. E. Beckman.

Prof. Pietro Corbetta, formerly professor of inorganic chemistry at the Milan Polytechnic, has died in his 72nd year.

The deaths of the following members of the Society in the United States have recently been announced:—Mr. J. Hasslacher, president of the Roessler-Hasslacher Chemical Co.; Mr. J. D. Pennock, general manager of the Solvay Process Co., Syracuse, N.Y.; and Dr. E. J. Lederle, a well-known chemist and bacteriologist.

CORRESPONDENCE.

THE ORIGIN OF THE SOCIETY OF CHEMICAL INDUSTRY.

Sir,—Mr. Douglas Herman, in his letter to the *Journal* of January 31 last, states that the chairman of the meeting held at Widnes at which members of the Faraday Club attended was Mr. James Muspratt, brother of Dr. E. K. Muspratt. Dr. E. K. Muspratt's brother was Dr. James Sheridan Muspratt. Mr. James Muspratt, chairman, would be Mr. James Liebig Muspratt, Dr. E. K. Muspratt's nephew, and son of Mr. Richard Muspratt, of Flint, N. Wales.—I am, Sir, etc.,

St. Albans, Martin Taylor.
March 22, 1921.

Sir,—The letter of Mr. John Hargreaves in the *Journal* for March 15 (p. 86 R) appears on the whole to confirm my own impressions, which were written mostly from memory. The only point at issue between us appears to be the relative influence upon the formation of the Society exercised by the members of the Faraday Club and by the Widnes chemists who wished to name the new society "The South Lancashire Chemical Society"; whereas I believe that the former were mainly responsible, Mr. Hargreaves gives his vote in favour of the latter. Can we not agree to admit that the credit is due to both?

Among the men who assisted notably in the formation of the Society of Chemical Industry I certainly ought to have mentioned the late Dr. Ludwig Mond.—I am, Sir, etc.,

Lyons, Douglas de L. Herman.
March 28, 1921.

PARLIAMENTARY NEWS.

Safeguarding of Industries.

A White Paper (Cmd. 1219) has been issued which sets out the proposed Ways and Means Resolutions to be discussed in the House of Commons prior to the introduction of the projected Bill dealing with "key" industries, etc.

Resolution I proposes the imposition for a period of five years of an import duty of $33\frac{1}{3}$ per cent. *ad valorem* on certain articles which include *inter alia*:—(a) Optical glass and optical elements, microscopes, spectroscopes, and other optical instruments. (b) Beakers, flasks, etc. and other scientific glassware and lamp-blown ware, evaporating dishes, crucibles, combustion boats, and other laboratory porcelain. (c) Scientific instruments such as balances, pyrometers, barometers, etc. (d) Wireless valves and similar rectifiers, and vacuum tubes. (c) Ignition magnetos and permanent magnets. (f) Arc-lamp carbons. (h) Metallic tungsten, ferro-tungsten and manufactured products of metallic tungsten and compounds (not including ores or minerals) of thorium, cerium and other rare-earth metals. (i) All synthetic organic chemicals (other than synthetic organic dyestuffs, colours and colouring matters imported for use as such, and organic intermediate products imported for their manufacture), analytical reagents, all other fine chemicals, and chemicals manfactured by fermentation processes. Articles falling under any of the above descriptions which may be contained in any list issued by the Board of Trade are also included.

Resolution II prescribes an *ad valorem* duty of $33\frac{1}{3}$ per cent. on "articles of any class or description in respect of which an Order by the Board of Trade has been made under any Act of the present Session for giving effect to this Resolution, if manufactured in whole or in part in any of the countries specified in the Order, or deemed to be so manufactured." The grounds on which such Order may be made are that the article in question is being sold or offered for sale in the United Kingdom (a) at prices below the cost of production, or (b) at prices which, owing to depreciation of the currency of the producing country, are below the prices at which similar goods can be profitably manufactured in the United Kingdom; and that by reason thereof employment in any home industry is being, or is likely to be, seriously affected. The term "cost of production" is defined.

HOUSE OF COMMONS.

Imports of Gas Mantles.

Sir P. Lloyd-Greame, replying to Lieut.-Col. Sir J. Norton-Griffiths, said that 12,668 gross of incandescent gas mantles had been imported from Germany during the period January 1 to March 31, 1921. The general condition of the gas-mantle industry had been considered, and its difficulties were known.—(Apr. 4.)

The Coal Crisis.

In moving a resolution under the Emergency Powers Act, 1920, Sir R. Horne made a statement upon the coal crisis, in which he said that, following on the last coal strike, it was agreed that the owners and the Miners' Federation should attempt to find a new basis for the payment of wages, but the owners desired that any wage basis should be settled district by district, whereas the miners contended that it should be a national settlement, although that involved a pooling system under which profitable undertakings would have to subsidise unprofitable ones. After the determination of decontrol was announced the owners gave notice that they could no longer continue on the same basis and were obliged to fix a new scale. So far the miners had refused to discuss the new rates with the owners, and this had led to the present stoppage. Apparently the issue was not one of wages, but whether there should be a subsidy or not.

Mr. Clynes claimed that the hurried determination of the decontrol of coal was the cause of the trouble, together with the magnitude and suddenness of the reductions in the rate of pay.

Mr. Lloyd George said that the Government would willingly assist in further conference, but it must be understood that there could be no maintenance of the coal industry out of taxation, no re-establishment of control, and that attempts must be made to stop the flooding of the mines.—(Apr. 5.)

The Paper-making Industry.

Sir W. Seager asked if the President of the Board of Trade was aware that out of 48,000 employees in British paper mills 26,201 were totally unemployed and 16,153 on part time, owing mainly to the dumping of paper from Finland, Germany, Sweden, and Norway.

In a written answer, Sir P. Lloyd-Greame stated that he was aware of the unemployment in the industry, and although this was probably accentuated by cheap imports from the countries named, it should be noted that Swedish currency had not depreciated compared with sterling, and that Norwegian currency had depreciated relatively little.—(Apr. 7.)

REPORT.

General Report on the Industries and Commerce of Spain (December, 1920.) *By* Capt. U. de B. Charles, *Commercial Secretary to H.M. Embassy, Madrid. Department of Overseas Trade. Pp. 72. London: H.M. Stationery Office.* 1921. *Price* 1*s.* 6*d. net.*

Spain is above all an agricultural country and produces, in addition to fruit and cereals, sugar, olive oil, and esparto grass. Both beet and sugar-cane are cultivated, but the former is the more important, as it is grown over nearly the whole country; cane would be grown much more extensively were larger supplies of basic slag available from England. The sugar industry is controlled by a trust. Spain is the largest producer of olive oil in the world; nearly 4 million acres are planted with the olive tree. The most productive regions are the provinces of Jaen, Cordova, and Seville, and the oil is extracted chiefly in Malaga and Cordova. The estimated production of oil in 1919 and 1920 was 3,360,000 and 2,632,500 quintals, respectively. Not more than 25 per cent. of the production can be classed as fine-grade oil. Export of the oil was prohibited in October, 1920, in order to conserve domestic supplies. Esparto grass grows wild in the mountainous districts near Aguilas and Almeria, and about 150,000 tons is harvested each year. It is chiefly used in the manufacture of paper and rope, but experiments are being made to produce a finer fibre, and one recently obtained compares favourably with the jute yarns used in the manufacture of sacking and fine twines. Export of this grass has fallen off during the last year, but the industry could be much expanded.

The mineral resources are very great, and large areas have not yet been surveyed. In 1918 the capital employed in mining enterprises was estimated at 984,821,000 pesetas, of which 569,630,000

pesetas was held by foreigners (peseta=9½d. at par). The value of the Spanish mineral production has risen by nearly 75 per cent. during the last seven years, but the output; except that of coal, has decreased owing to industrial troubles, high working costs, and transport difficulties. Iron ore constitutes one of Spain's greatest economic reserves; the provinces of Viscaya, Santander, Almeria, and Huelva are the chief producers. The output of the province of Huelva is mainly iron pyrites. The highest-grade hæmatite ores are gradually being worked out, and it may soon be necessary to exploit deposits more distant from the coast. At present the industry centres round Bilbao, Santander, and Huelva, the output of pig-iron and steel is increasing, and there are now over 30 blast furnaces. The output of steel is almost entirely controlled by a combination of five manufacturing firms, called the Central Siderurgica.

The principal coalfields are situated in Asturias, Penarroya in Central Spain, and the Ebro district, the yearly production being now about 6 million tons. Much interest is being taken in the development of the coal deposits, but lack of experienced miners and modern plant has impeded progress. It is to be hoped that Great Britain will soon regain her former position as an exporter of coal, as the Spanish market is in danger of being lost to the United States. The lead and silver lead mines are mainly situated in the provinces of Cordova, Jaen, Murcia, and Badajoz, and practically the whole output of copper ore comes from the province of Huelva, where the British-owned Rio Tinto and Tharsis mines are the largest producers. Large reserves of zinc ore are stated to exist in the provinces of Santander and Murcia. Almost the whole of the manganese ore produced came from the province of Huelva, where it is found as a silicate with 28—32 per cent. manganese; the output has increased greatly owing to the cutting off of Russian supplies. The production of ores, minerals, metals, etc., in 1919 was as follows:—

	Tons.		Tons.
Coal and lignite	6,243,509	Zinc ores ..	103,608
Coke, etc.	1,027,936	Zinc metal ..	16,313
Lead and silver-lead ores	178,055	Mercury ores ..	24,966
Iron ores	5,071,249	Mercury metal ..	1,226
Iron and steel	835,356	Manganese ores ..	66,685
Copper ores	1,470,090	Superphosphates .	135,526
Copper metal	34,369	Cement	363,450

The total value of the production at the mines was 499,662,644 pesetas, and the value of the metals etc. at the works was 566,428,928 pesetas. Other minerals found in Spain are potash (the deposits at Cuna, in Barcelona, are said to contain nearly a million tons), salt, phosphates, wolfram, tin, bauxite, ochres, graphite, sulphate of soda, tripoli, and immense quantities of marble, granite, and other building materials.

The development of Spanish industry was greatly stimulated by the war; the machinery, metal, chemical, and textile industries made the most progress, but with the return of peace this advance has not been maintained. With few exceptions, Spanish goods are still far behind the standard of imported goods, and trade is being lost by the short-sighted policy of maintaining fictitious prices.

Although labour is plentiful, the political situation, the shorter working day, and decreased output are seriously affecting trade. The reaction began in 1919, and by the end of 1920 the country was filled with alarm. The total exports in 1919 were valued at 1,316,275,000 pesetas (£52,651,000 at par); about one-half consisted of foodstuffs, and one-sixth of raw materials. The export figures for the first nine months of 1920 are about one-fifth lower than those for the corresponding period in 1919, but mineral exports exceed those of 1919 by about 50 per cent., and chemicals show a gain of 7 per cent. The value of the imports has rapidly increased during the last two years, the aggregate value during January—October, 1920, exceeding those of the corresponding periods in 1919 and 1918 by 32 and 130 per cent. respectively. Imports of chemicals and fertilisers increased by 60 per cent. over those in 1919; 65,500 t. of nitrate was imported from Chile and England, and other fertilisers came mainly from the United States. The United Kingdom was the chief source of mineral colours, varnishes, and writing ink, whereas printing ink and coal-tar colours came largely from the United States. The United Kingdom also supplied practically all the tinplate, a large proportion of the imports of iron and steel, and most of the pharmaceutical products. U.K. manufacturers have a good prospect of recapturing the trade in heavy chemicals, now in Dutch and Belgian hands. British goods are preferred, and the future of British trade in Spain should be assured if local requirements are studied sufficiently.

TRADE NOTES.

BRITISH.

Seychelles in 1919.—The export of copra in 1919, 4328 tons valued at Rs.1,445,722, was considerably greater than in previous years. The cultivation of the coconut has been improved, attention has been paid to its diseases, and experiments have been made on the use as fertilisers of seaweed, ash from the distillation of essential oils, and guano. Nineteen times more rubber was exported than in 1918, the 1919 crop being 27,260 lb. Para rubber grows well, if slowly, but the tapping is badly done. Essential oils are important products, and in 1919, 44 factories produced 24,430 litres of cinnamon-leaf oil, which fetched high prices on the London market. *Ocimum viride* oil, produced experimentally, was found to contain over 50 per cent. of thymol and the cultivation of the plant has been taken up. Ambrette seeds are no longer grown, as they are produced more cheaply elsewhere. Fibre from *Fourcroya gigantea* is made in increasing quantities, and the plant, like sisal, could be grown on a large scale. The exports from the colony were valued at Rs.2,101,377, the chief destinations being France (Rs.1,113,787) and the United Kingdom (Rs.705,422). Imports were valued at Rs.1,125,316, those from the United Kingdom showing an increase of Rs.53,795 compared with 1918.—(*Col. Rep.—Ann., No.* 1061, *Feb.*, 1921.)

FOREIGN.

Proposed Japanese Duties on Soda Products.—According to *The Times*, the Japanese Government has introduced a Bill to increase the import duty on caustic soda by 100 per cent., and that on soda ash and natural soda by 400 per cent. Such increased duties would affect the Japanese glass industry, which exports glass to the value of £1,500,000 yearly, and also British manufacturers of soda compounds

Soda Trade in Manchuria.—There is a considerable demand for soda ash, bleaching soda and caustic soda in the Mukden district; Great Britain and its colonies supply all three of these, Japan only the first two, and the United States practically none. According to the customs returns, 54,286 tons of soda compounds was imported into China during 1919, of which 6316 t. was disposed of in Manchuria. The British Empire supplied 74·5 per cent. of the total Chinese imports, Japan 14 per cent., and the United States 11 per cent.—(*U.S. Com. Rep., Jan.* 14, 1921.)

Japanese Tanning Industry.—This industry developed considerably during the war, and large quantities are now used of galls, oak bark, mangrove bark, quebracho wood and various extracts, principally catechu and persimmon. The persimmon extract is made from a tree grown for the purpose, and an exportable surplus is produced. Imports of tanning materials and tanning extracts in 1919 amounted to 24,876 and 72[illegible]1 short tons, respectively; they were derived mainly from South Africa)57%), British India (29%) and China (10%); and the sources of the imported extracts were:—Dutch East Indies (34%), Argentina (22%), and the Straits Settlements (21%).—(*U.S. Com. Rep., Jan.* 22, 1921.)

State of Japanese Trade in January, 1921.—The state of the Japanese export trade was still unfavourable in January, and there was little prospect of improvement; imports were also small, and are considered certain to exceed exports for a time. The general financial position, however, was much better than was anticipated at the end of 1920. Stocks of copper amounted to 30,000 tons and were increasing. Reductions had been made in the prices of all products of the Government iron foundry at Yawata, but as the quotations were above market level, consumption can scarcely be affected; stocks in hand at the foundry amounted to 370,000 tons. Such large stocks of European paper had accumulated that manufacturers have reduced production as far as possible, and a fall in prices was anticipated. The depression in the match industry was most severe; many of the smaller manufacturers have suspended operations; all the large companies have made losses, exports have declined by 75·6 per cent., as China, formerly a large customer, is developing an industry of its own, and Swedish competition is growing. Belgium was competing strongly in the glass trade and exporting large quantities of window glass; local prices have been reduced but the decline in export was leading to a diminished output. German reparation dyes were still arriving, but the demand was negligible and stocks were estimated at 290 long tons (aniline dyes 197 t., alizarin 18 t., and synthetic indigo 78 t.).—(*U.S. Com. Rep., Mar.* 10, 1921.)

Siamese Imports of Chemicals and Drugs.—Chemicals and drugs are not manufactured in Siam, and it appears likely that increasing quantities of these materials will be imported in the near future. The imports of chemicals in recent years (the Siamese fiscal year ends on March 31) have been:—1917–18, 949·8 metric tons (£32,245); 1918–19, 1088·4 t. (£52,039); 1919–20, 916·4 t. (£42,995); whilst imports of drugs were:—1917–18, 903·8 t. (£98,910); 1918–19, 980·6 (£137,528); 1919–20, 971 t. (£424,319). The values given assume normal rates of exchange. Hitherto the bulk of the Siamese trade in chemicals and drugs has been in European hands, but the proportions supplied by the United States increased from 1·7 to 4·1 per cent. of the chemicals in 1918–19 and 1919–20, and from 0·7 to 3·5 per cent. of the drugs imported during the same period.—(*U.S. Com. Rep., Feb.* 7, 1921.)

Chinese Trade in Rubber Goods.—Practically no rubber goods are manufactured in China, and the imports of crude rubber and guttapercha are extremely small; in 1919, a record year, they were only 40 tons. The market for tyres, though limited to the few districts with good roads, is steadily developing and the value of the net import of motor-car tyres into the Shanghai district is ten times greater than in 1913. Tyres and other rubber goods rapidly deteriorate on keeping, and therefore big stocks cannot be held. There is an excellent demand for rubber goods such as gloves, hot-water bottles, vulcanite, etc., but the market for rubber foot-wear and clothing is small, although proofed fabrics apparently sell more readily. The chief port of entry for rubber and rubber manufactures is Shanghai, followed by Dairen, and the import duty is 5 per cent. *ad valorem*, plus 5 per cent. of the duty charges for wharfage and warehouse dues. —(*U.S. Com. Rep., Jan.* 19, 1921.)

COMPANY NEWS.

BRITISH DYESTUFFS CORPORATION, LTD.

The second ordinary general meeting was held on April 1, in Manchester. Sir H. Birchenough, who presided, referred to the late Lord Moulton's services to the dye industry, and then commented upon the report and accounts. In spite of the fact that only a part of the capital had been remuneratively employed, the year ended October 31 last was a satisfactory one. The profit, after allowing for depreciation and taxation, was £552,100 (issued capital £9,202,093), out of which the full 7 per cent. dividend on the preference shares had been paid; a dividend of 8 per cent. on the preferred ordinary shares was recommended, leaving £203,304 to be carried forward, as against £58,826 brought in. The sum of £289,366, inclusive of capital expenditure, had been spent on research during the past two years, and preliminary expenses figured among the assets at £251,551. On October 31 stocks in hand were valued (at cost or market price) at £3,998,543. The sum of £593,486 had been set aside to cover depreciation during the past two years, and in view of present trade conditions the directors had decided to suspend expenditure on constructional work.

The policy of the Corporation was to establish and develop a dyestuff industry which would gradually supply all the requirements of British consumers, and that progress in this direction had been made was evidenced by the fact that the increase in output was 54 per cent. above that for the previous year. Trade was so active during the early part of the year that all the demands of the colour-users could not be met, although sufficient dyes were supplied to enable them to take advantage of that period of unexampled prosperity. As the year 1920 advanced conditions became gradually worse owing to the flood of German imports and the general decline in trade. Every effort had been made to develop the Research Department under the direction of Prof. A. G. Green and Dr. R. Robinson, but the system of dual control by two managing directors had proved unsuccessful; it had been decided to replace the latter at an early date by one individual, but in the meantime the executive powers of the board would be vested in the chairman and two of the new directors, Sir W. Alexander and Mr. Vernon Clay, chairman of the Colour Users' Association (the third new director being Field-Marshal Sir W. Robertson). The late managing directors had been appointed ordinary members of the board, and the immediate duty of the new executive committee was to organise adequately the staff of the Corporation.

On questions being invited, Mr. J. Parker Smith moved that the adoption of the report should be deferred pending the report of a committee of investigation, but that the accounts be approved and the dividend on the preferred ordinary share be paid. He criticised very adversely the supersession of the two managing directors, Sir J. Turner and Dr. H. Levinstein, who had been the mainstay of the dye-making industry in this country. After a succession of speakers had spoken in favour of the amendment and several had demanded the reason

of the summary action taken against the two managing directors, the chairman said that the board could not agree to the course proposed, and that he was not prepared to argue the matter at a general meeting. The decision had been made after deliberate consideration; it was well known that the managing directors had not co-operated harmoniously, and the interests of the Corporation demanded the termination of their contracts. On a show of hands the amendment was declared lost by a narrow majority, and another amendment—that the appointment of the new directors be not confirmed—was rejected on a poll.

BORAX CONSOLIDATED, LTD.—The Rt. Hon. the Earl of Chichester, in presiding at the general meeting of this company held on March 21, said that the net profits for 1920 amounted to £476,581, compared with £442,023 in the previous year. The total of the reserve funds was £827,179 (issued capital £4,494,978, inclusive of debentures). A very large amount of ore was in sight, stocks stood at £506,617 on September 30, and the sum of £664,415 was on deposit and current accounts. A Continental works had recently been purchased on favourable terms, and other developments were contemplated. There were signs of recovery from the present bad trading conditions. Dividends on the deferred ordinary shares amount to 15 per cent. for the year.

BRITISH ALUMINIUM CO., LTD.—Addressing the annual meeting on March 31, Mr. A. W. Tait, chairman, stated that the company had achieved a record output and record sales during the year 1920; the great demand during the early part of the year could not be fully met. The company took over the entire Government stock of aluminium, all of which had now been disposed of. The period of financial stringency, which began last August, led to a serious disturbance of the motor trade and of the aluminium industry. Adverse conditions still prevailed, although there were signs of improvement; meanwhile the company was restricting its output. A great future awaited the application of suitable aluminium alloys in the motor trade and in general engineering, in the electrical industry, and in the manufacture of domestic utensils. Additions had been made to the alumina works in Scotland, and to the rolling mills at Warrington. The company had again taken steps to acquire additional water power in Scotland, and had modified the scheme put forward in 1918, which did not obtain Parliamentary sanction, in such a way as to allay local opposition. The new Bill had passed its second reading in the House of Commons. Some further work had been done on the company's power scheme at Orsières in Switzerland, but operations had since been suspended pending more favourable times. The profits for the year were £348,108 (issued capital, with debentures, £2,637,189), and the directors recommended a dividend on the ordinary shares bringing the total dividend upon them for the year up to 10 per cent. The liquid resources of the company were satisfactory.

NEW ISSUES.—Lever Bros., Ltd. has made an issue of £4,000,000 seven per cent. first mortgage debenture stock at 92½ per cent., redeemable at par in 1941, or in 1931 at the option of the company. The authorised share capital of this company is £130,000,000, of which £46,996,499 has been issued; assets at December 31 last were valued at £50,734,770. The Mond Nickel Co., Ltd. has offered £1,300,000 of 8 per cent. mortgage debenture stock at 98, redeemable in 1941 at 104 per cent. The issue was quickly subscribed. An issue by the British Oxygen Co., Ltd. of £250,000 of 8 per cent. first mortgage debenture stock at 96 per cent. was also rapidly taken up.

OFFICIAL TRADE INTELLIGENCE.

(From the Board of Trade Journal for March 24, 31, April 7.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of Firm or Agent.	Materials.	Reference Number.
Australia	Crockery, imitation leather ..	362
British West Indies	Glassware	426
Canada	Artificial silk yarns	393
"	Crockery, glass, scientific instruments, chemical plant, sugar machinery (catalogues of) ..	*
"	Drugs	‡
"	Creosote	—
Cyprus	Fertilisers, soda crystals	427
New Zealand ..	China, glassware	398
Belgium	Pitch	372
Bulgaria	Creosote, zinc chloride	—

* H.M. Trade Commissioner, 257/260, Confederation Life Buildings, East Queen Street, Toronto, Canada.

‡ High Commissioner for Canada, 19, Victoria Street, London S.W. 1.

TARIFF. CUSTOMS. EXCISE.

Australia.—As from April 1, licences for the import of foreign dyes, whether from stocks in the U.K. or not, are subject to permit issued by the High Commissioner's Office.

Austria.—Import licences are now required for certain leather and leather wares, and export licences for tanning materials, leather and leather wares (with some exceptions).

Belgium.—It is proposed to increase the customs duties on, *inter alia*, photographic apparatus, perfumes, pottery, glassware (except bottles), and mineral waters.

Licences are no longer required for the export of bottles, demijohns, cylinders for compressed and liquefied gases, carbonate of soda, natural cement, undressed hides and skins, superphosphates, linseed, rape-seed, scrap metals, coal-distillation products, and pyrites residues.

The export of bricks, artificial cement, raw bones, and fertilisers (except superphosphates) is subject to licence, but fertilisers, except potash salts, may be exported without licence as from June 1.

Bulgaria.—Export duties have been reduced on certain skins and edible fats.

Federated Malay States.—The export of china clay, felspar, and china stone is prohibited as from January 7.

Fiji.—The complete text of the revised customs tariff schedules may be seen at the Department, 18, Queen Anne's Gate, London, S.W. 1.

Exportation of gold and silver coin and bullion, rice, and raw sugar is prohibited as from December 15, 1920.

France and Algeria.—The export duty on oilcake has been modified.

The restrictions on the import of cellulose pulp and of paper in rolls have been withdrawn.

Greece.—The restrictions on the import of calcium carbide have been removed.

Grenada.—Additional export taxes have been levied on cocoa, cottonseed, nutmegs, and mace.

Italy.—Export licences are no longer required for manganese ore, magnesite bricks, newsprint paper, quinine salts, copper sulphate, and zinc waste.

Lead and zinc ores are again subject to export licence.

Malta.—The metric system of weights and measures will be used in levying customs duty as from July 1. Articles affected include alcohol, alcoholic beverages, malt, edible oils, petroleum, saccharin, sugar, spirit varnish, and vinegar.

Martinique.—The export duty on sugar has been increased to 21 fr. per 100 kg.

Netherlands.—The prohibition on the export of phosphatic fertilisers, glass powder, wood, zinc ore, and zinc oxide has been withdrawn.

The export of 240,000 metric tons of sugar-beet will be permitted, although the export prohibition remains in force.

Import duties have been increased on chloral hydrate, sulphuric and acetic ether, collodion, chloroform, spirit of nitrous ether, and similar substances prepared from or with alcohol.

New Zealand.—The regulations relating to the standards and labelling of vinegar are set out in the issue for April 7.

Nigeria.—Non-proprietary medicinal preparations containing alcohol imported by registered medical practitioners, dentists, and licensed druggists may be exempted from duty by the Governor in Council.

Portugal.—Paper fabrics and earthenware insulators now pay an increased customs duty.

Rumania.—The export duty has been modified on certain petroleum products and on oilcake.

Serb-Croat-Slovene State.—The export of all goods is allowed under conditions laid down in the Decree of April 16, 1920, with some exceptions, among which are sugar, gold, silver, and scrap iron.

Spain.—The export duty on oilcake has been abolished, but the export thereof is still subject to licence.

Switzerland.—Importation of industrial alcohol by private persons is prohibited.

As from March 18, import licences are required for paper, cardboard, and wares thereof, and for glass bottles.

Special export licences are required for, *inter alia*, cocoa powder, condensed milk, waste paper, scrap iron, copper turnings, precious metals, saccharin, potassium permanganate, indigo, and certain coal-tar colours.

Tunis.—Sugar may now be imported freely under certain specified conditions.

GOVERNMENT ORDERS AND NOTICES.

EMERGENCY REGULATIONS, 1921.

An Order in Council, issued on April 4, under the Royal Proclamation of Emergency, makes Regulations which empower the Government to take possession of land, works, plant, food, material, stores, etc., to regulate transport by road, light railway or canal, and requisition vehicles, to close ports and harbours, prohibit exports, control the supply of gas, water, electricity, and motor spirit, and to take possession of all or any coal mines, together with any plant, vehicles, railway wagons, etc., necessary for maintaining the supply and distribution of coal.

Coal Emergency Directions.—The Coal (Emergency) Directions, 1921, issued by the Secretary of Mines provide for a reduction of 50 per cent. in the industrial consumption of coal and fuel derived therefrom, prohibit the shipment of coal either as cargo or bunkers save with the permission of the Secretary for Mines or a person authorised by him, and regulate the supply and distribution of coal. Lighting used for advertisement and display is prohibited, gas and electricity companies are empowered to reduce the supply in order to economise coal, and the use of gas or electricity for power production is restricted by 50 per cent. The Directions came into force on April 2.

Prohibited Exports.—Licences are no longer required for the export to Russia of any goods other than those the export of which is prohibited, except under licence, to all foreign countries.

REVIEWS.

Les Ethers Cellulosiques. *Pt. I.: Les Ethers Minéraux de la Cellulose. Vol. I.: La Nitrocellulose et le Celluloid. By* André Dubosc. *Pp.* 334. (*Paris: A. D. Cillard.* 1920.) *Price* 45 *francs.*

A book bearing this title naturally attracts the attention of celluloid chemists, explosives chemists, and that increasing number of scientists who are investigating the colloidal behaviour of nitrocellulose. It is to be feared that each class will feel some disappointment after reading the book. Celluloid chemists and explosives chemists will find, it is true, a number of full descriptions of plant and processes, but not much that is new, and they will occasionally find that the data relating to the two industries are difficult to disentangle. Colloid chemists, on the other hand, will find little that is of interest, except some generalities on the colloidal constitution of celluloid. Possibly later volumes will be more stimulating in this respect. Some most important researches on nitrocellulose which have a direct bearing on the constitution of celluloid have recently been published, and it is to be hoped that the author will discuss these in due course.

The present volume deals with the manufacture of celluloid as far as the preparation of bleached and washed nitrocellulose pulp. It opens with a historical introduction, in which the author accepts the account of the discovery of celluloid given by Chandler (*cf.* J., 1914, 225) on the occasion of the presentation of the Perkin medal to J. W. Hyatt in 1914. This account led at the time to a somewhat acute discussion (*cf.* J., 1914, 678) on the relative claims of Hyatt and Daniel Spill, in which neither side perhaps did justice to the versatile genius of Alexander Parkes; however, the claims of

Parkes to fame rest also on his researches in electro-deposition and metallurgy, and there is no need to reopen the discussion. The chapter on the physical and chemical properties of celluloid will prove the most interesting to those outside the industry, and here one is impressed with the absence of direct experimental evidence for the theories advanced. The truth is that the experimental difficulties are so great and the complications so many in the case of the concentrated plastic masses obtained in celluloid manufacture that the results obtained from experiments can only be empirical. It is usually impossible to control experiments so that only one factor varies at a time, which is the ideal condition sought for in research. How many chemists would be prepared to assert that any two samples of nitrocellulose were identical? This difficulty arises at the outset, and since the nitrocellulose must be bleached, pulped, washed, dried, blended with solvents, kneaded, rolled, pressed, sliced, and stoved, and since, moreover, a few minutes more or less spent in some of these processes may profoundly modify the properties of the product, it is frequently impossible to ascribe the difference between any two samples of celluloid to a single cause. We are forced to conclude that the systematic study of solid celluloid must start with dilute solutions of nitrocellulose, and, although the author's views on the colloidal phenomena accompanying celluloid manufacture are interesting, we think that, for the present at any rate, they will prove sterile. A more promising system of attack would be to examine Bingham's division of colloid solutions into viscous liquids and highly mobile plastic solids, and to investigate nitrocellulose solutions in varying concentrations from this point of view. Until we know more about the distribution of solvent between the phases in dilute nitrocellulose solutions, we cannot expect to understand much about the constitution of solid celluloid.

The raw materials of celluloid manufacture are treated fully, and the author has made good use of the information contained in papers read before this Society by de Mosenthal (*cf.* J., 1904, 292; 1911, 782). The chapter on nitration is preceded by a theoretical discussion on etherification, which, although not directly applicable to the nitration of cellulose at present, is perhaps a useful caution against too much rule-of-thumb in the control of the factory operation. The somewhat obvious mathematical treatments of nitration and doping due to Clément, which have already been published more than once, are less useful than Fowler's graphical method (*cf.* J., 1919, 34 T), and might have been omitted, as well as some of the ancient formulæ dating back to the infancy of the industry. There is an interesting section on the Thomson displacement process in which the author sums up strongly against its applicability to the manufacture of nitrocellulose intended for celluloid manufacture. The last two chapters deal with stabilisation, washing, pulping, and bleaching, and due emphasis is placed on the necessity for using pure water and for avoiding any process which will injuriously affect the colour of the product. This important distinction between explosives practice and celluloid practice is not always appreciated.

There are no illustrations of plant in the book, which detracts from its usefulness. The type is good and only a few misprints have been encountered, among which "Van T. Hoff" has a quaintly American flavour. It is to be hoped that in the succeeding volumes M. Dubosc will break away still further from the tradition that books on nitrocellulose should be merely abstracts of patents of varying vitality, and will discuss the problems of celluloid manufacture in the light of his own unquestioned experience.

F. Sproxton.

Indian Tanstuffs. *By* J. A. Pilgrim, *Government of India, Board of Industries and Munitions. (Calcutta: Superintendent Government Printing, India, 1920.) Price 6 annas.*

The Government of India is to be congratulated on the production of a short, concise report of valuable chemical research in which the practical and commercial application of results is not overlooked. Mr. Pilgrim's handbook contains the results up to April, 1920, of his and Mr. W. Fraymouth's examination of the barks, leaves, fruit, etc. of Indian forest species, mainly from the point of view of manufacture of tannin extracts for export. The requirements of the Indian tanner, *i.e.*, cheap tanstuffs to be used in direct contact with the hide, are also not lost sight of. With the exception of one or two species, which are duly noted, many samples of each tanstuff have been examined, and it is evident that the sampling of each bark or leaf has been carried out with great care, thus greatly increasing the value of the conclusions arrived at. Hide-powder estimation of tannin is not an exact analysis, but if used as Mr. Pilgrim evidently uses it, it is of great value in determining the tannin value of barks, etc. We consider the publication of negative results, *e.g.*, those on pages 24 and 25, as of great value. It is not always appreciated that negative results are as valuable as positive results in research work.

Analyses and practical leather-making have established the value of Thawai (*Woodfordia floribunda*) bark, and if this could be produced at a low price in quantities, it is clear that it would threaten the consumption of South African wattle. It is to be regretted that the present bulletin does not contain figures of cost of the tanstuffs as the earlier bulletin did. It would be best to express these in shillings per unit of tannin per ton, free on rail in India. This applies also to a recent report in a trade paper showing extraordinarily favourable figures of tannin and non-tans in certain oak and chestnut barks which have been studied in Northern Burma (presumably by Mr. Pilgrim). Nothing whatever is said of the distance from the rail at which the forests of these trees are found, nor whether labour is available at reasonable prices for collecting the barks. Mr. Pilgrim continues the practice of examining samples of bark from each part of the tree, and we would urge that a full range, from bole, low branches, high branches, twigs, etc., should be studied in every case where the first examination demonstrates the possibility of a valuable source of tannin.

The principle adopted in the earlier researches at Maihar, viz., to collect the tanstuff without destruction of the tree, appears to have been less rigorously followed in the later work recorded in this report. The history of the tanner's bark has always been the same. A cheap and good bark becomes expensive as the demand grows and as the most accessible forests are depleted. It was so with English oak, with hemlock, and now with South African wattle, although in this case the bark exploiters have replanted vigorously. It appears probable that, other conditions being equal, the bark which can be got without destroying the trees will finally hold the market.

In a thoughtful preface Mr. Pilgrim explains his principles in studying Indian tannins from the point of view of extract-making. Unfortunately he adopts the standard of "crystals." It is a fact that all the biggest tanners, in Britain at any rate, if they use solid extract at all, demand a clean-fracture solid which generally contains more moisture than the 5 per cent. carried in "crystals."

The extent and resources of the forests of the Indian Empire are as yet little known in Britain, but now that the Forest Research Institute at Dehra Dun has received bigger grants and has engaged several new scientific officers, it is to be

expected that regular reports on the progress of research will appear. It is to be hoped that after the present trade depression is over, British financiers will study the work done and take the earliest opportunity of exploiting new discoveries. During the years before the war a large number of German firms in India had commenced such exploitation. The opportunity presented now by the absence from India of all ex-enemies will not last for ever, and the presence in India of other than British firms should be closely watched, if the spirit of the new reforms, *i.e.*, close co-operation between the Britisher and the Indian, is to be followed.

Text Book of Chemical Engineering. *By* Edward Hart. *Pp.* 211, *with* 200 *figures. (Easton, Pa.: The Chemical Publishing Co.; London: Williams and Norgate.* 1920.) *Price 4 dollars.*

There are not many text-books of chemical engineering, and therefore many chemists will welcome the opportunity of reading this small but attractive book, which is printed in good style, with profuse illustrations. The reading matter is, on the whole, very good, but all too brief to be of great service to the chemical engineer. As stated by the author, the book is primarily intended for the use of the college student and purposes to give him a general idea of the type of plant employed for standard operations in the chemical industry. Comparisons of one system with another are seldom attempted; these, though apt to be invidious, are very helpful. Exposition of the theory underlying the design or operation of the plant is also lacking. Historical matter is curtailed to a minimum and old-fashioned, inefficient appliances are omitted. For this reason the book gains in conciseness and can be said to be quite up-to-date as regards the subjects treated.

The chapters on crushing, filtration and drying re specially good, except for the lack of critical omparisons. Probably most industrial chemists ould regard the chapters on boilers, prime movers nd plumbing as superfluous, though the college tudent will, no doubt, find them useful.

There appear to be few errors of commission, ut, naturally, a good many of omission. We do ot find, for example, any information with regard o water, gas and electricity supply, disposal of aste, centrifugal pumps, electrostatic precipitaion, furnaces, gas washing, recovery of light spirit, ractional condensation, refrigeration, liquefaction, eat exchange, etc.

Whilst the general quality of the illustrations, hich fill more than half the pages, is excellent, a ew are distinctly open to criticism. For example, he circular stoneware tower appearing as a fullage illustration on page 63 (and again on page 00!) shows acute and right-angled pipe-bends, hich the engineer tries to avoid. Some of the llustrations, for example, figs. 188 and 189, are ot accompanied by the necessary descriptive and xplanatory text. Fig. 154 is badly drawn.

As a short and handy book for students this work as much to commend it.

W. B. Davidson.

Corrigenda.—In the issue for March 31, p. 113 R, under Legal Intelligence, Rail Conveyance Classification of a Washing Powder, substitute "Class C" for "Class 2" in lines 8, 15, and 26; and in lieu of "soap powder" read "washing powder" in lines 11 and 24.

OBITUARY.

LORD MOULTON OF BANK.

By the death on the 9th ultimo of Lord Moulton the Society has lost one of its most brilliant members. From New Kingswood School, Bath, John Fletcher Moulton went to Cambridge (St. John's College), where he became Senior Wrangler and First Smith's Prizeman. He took his M.A. degree of London University, and later that of Cambridge, becoming soon after a Fellow of Christ's College. Resigning his Fellowship in 1873, he was called to the Bar in the following year, taking silk in 1885. As the most successful patent lawyer of his day, he acquired knowledge of the arts of the chemist, the physicist, and the technologist, so that he had understanding of their language and their writings, a possession of special importance in handling the great number of legal cases pertaining to industry, and especially chemical industry, in which he was engaged. He was a member of the House of Commons, a Lord Justice of Appeal, a Lord of Appeal, and a Privy Councillor.

Here, in all probability, this notice would have concluded had it been written before August, 1914.

But war came, and Lord Moulton, then 70 years of age, placed his talents and his energies at the disposal of his country in her hour of trial. He first took up the matter of dye production—German supplies having suddenly ceased, leaving the textile industries faced with the impossibility of finishing their productions—the politicians' cry of "Business as usual" ringing more clearly in the ears of the nation than the danger alarm raised by the few who knew Germany and German aims. But it was quickly realised that the country was confronted with more serious tasks than the dyeing of cottons and silks, and, putting dyes for the time being on one side, Lord Moulton was entrusted with the chairmanship of a small advisory committee on high explosives. At that time the British Government made propellants but no high explosives, except a little tetryl (trinitrophenylmethylnitroamine) at Waltham Abbey. Picric acid, the standard one, was purchased from a limited number of contractors in relatively small quantities. TNT had hardly come upon the scene; its manufacture from toluol had been proposed to the writer some time before the outbreak of war, but in response to his inquiry as to the attitude of the War Office, he was told it was not favoured, although it had been brought into use in Germany. In England it was used only for minor purposes and in very small quantities—practically as a by-product of the dye industry.

The nation's pitiable plight of unpreparedness both in raw material supplies and in large scale processes soon became increasingly apparent. Germany had monopolised the organic chemical industry so completely that the greatest difficulties were experienced in this country when she was suddenly called upon to produce nitro-compounds in large quantities. We were short of plant, of trained chemists, and of manufacturing knowledge. Lord Moulton realised, more than any man, the inadequacy of our resources and the magnitude of our requirements. As chairman of the High Explosives Committee (A.6) under the Director of Artillery, his powers were gradually extended until in February, 1915, he had liberty to utilise to the utmost the capacity of the country. Four months later he became Director-General of the Department of Explosives Supply in the newly formed Ministry of Munitions of War. In order to work out the chemical and technical problems involved in manufacture on the necessary scale, the whole chemical industry throughout the length and breadth of the land was organised and co-ordinated

under his direction, no undertaking being too small to be entrusted with a share of the task. The production of the necessary raw materials was similarly dealt with, and before many months passed both crude- and final-product manufacturers were working in friendly consultation and competition, inspired by a most efficient system of costing and yield-checking worked out and put into operation at the headquarters of the department.

The preparation of high explosives was beset with greater difficulties than that of propellants, for besides the Government factory several private firms were well versed in the manufacture of cordite. On the other hand, the resources for picric acid (the standard high explosive) were inadequate not only as regards manufacturing capacity but also as regards raw material. This led to the manufacture of synthetic phenol and the inauguration of the production of TNT. As neither of these substances could be turned out in quantities sufficient to satisfy shell-filling requirements, Lord Moulton urged the addition of ammonium nitrate explosives, such as ammonal, schneiderite, and, later, amatol. Numerous problems of filling, detonation, and exploding were thereby introduced which required close investigation. Ultimately all troubles were overcome and the mixed explosives, in the preparation of which enormous quantities of ammonium nitrate were required, were entirely successful. The difficulties besetting adequate production were increased by the high standard of purity necessary for Service purposes, and the specifications were being constantly revised in order to reconcile quality and quantity. It has already been stated that the manufacture of TNT was practically new in this country, and Lord Moulton played a large part in raising it from small beginnings to a very large scale. This needed the organisation of materials, methods, and plant, with which he kept in close touch and in the development of which he rendered great assistance. Originally slow and wasteful, the processes were ultimately improved until they showed an efficiency upon which it would be difficult to improve. Purification methods were of great importance. These were originally attached to each plant, but one or two accidents led to their removal to separate works. The original process was crystallisation from alcohol, afterwards abandoned for washing in the cold first by alcohol, and later with sulphite. The latter method was introduced by Lord Moulton from France, where he found it in use. Safety precautions was another matter requiring careful watching, and Lord Moulton organised a special "Safety of Factories Branch" for the independent inspection of the many chemical factories. The fixation of nitrogen did not mature during the war. It formed the subject of investigation by a separate body, the Nitrogen Products Committee, of which Lord Moulton was a member. He several times expressed the opinion that one of the chief determining factors which induced Germany to choose August, 1914, as the date for launching the war was the perfecting and extension of the Haber process—without synthetic nitrates she would have lost the war within a year or less. Our own dependence upon imported nitrates was one of the weakest links of our defence, and the destruction of ships carrying them caused great anxiety and at times acute shortage.

In the spring of 1918 Lord Moulton took up the supply of poison gases, and this necessitated the establishment of factories for their production. The work was very distasteful to him, but he prosecuted it with vigour and entered closely into all the chemical and technical problems involved, which were naturally very numerous. The chief products were dichlorodiethylsulphide, phosgene, chloropicrin, and some arsenic compounds.

Lord Moulton was an energetic advocate of the establishment of a British dye industry on a scale large enough and strong enough to stand up against German competition, and he became Government representative and chairman of British Dyestuffs Corporation, Ltd., in 1919, holding the position until the following year, when he returned to his judicial labours.

It is not too much to say that under him the whole chemical industry of the country was not only reorganised on a basis enabling it to fulfil its war-time tasks, but also, and only second in importance, to meet adequately the post-war requirements of the nation. No man was better able to undertake two tasks of such magnitude. He was not merely an able lawyer, but a far-seeing and cultured man of the world and its affairs; and among other qualifications the possession of a large fortune acquired at the Bar must not be overlooked, since it placed him in a position of unassailable security in dealing with Governmental methods and red tape which might have weighed against the success of one less prominently and assuredly circumstanced. His name will be indissolubly connected with the future of chemical industry in Great Britain.

TOWARDS UNITY.

It is encouraging to note that the various proposals relating to the organisation of chemistry in this country which have been put forward from time to time by the Federal Council for Pure and Applied Chemistry have met with a uniformly favourable reception, and that the only criticism heard is that action has been too long delayed. In other words, to use Matthew Arnold's phrase, appreciation has been the soul of criticism, and this circumstance affords a very happy augury of benefits to come.

An important move in the direction of unity was made by the Council of the Society of Chemical Industry at its last meeting, when, in response to a suggestion received from the Council of the Chemical Society, it was resolved unanimously that the existing machinery of our Local Sections should be made available to a certain extent to members of the Chemical Society, the Society of Public Analysts, and, by implication, to members of other chemical organisations. The specific suggestion referred to was that papers on pure chemistry, whether contributed by members of the Society of Chemical Industry or others, should be accepted for reading at the meetings of our Local Sections, and that the Chemical Society should consider for publication any such papers sent on to it by us. The Council of this Society, in approving the suggestion as a council, decided to recommend its adoption to the Local Sections, and to leave details to be settled later.

The advantages to be derived from such a scheme are many. For some time past there has been a congestion of papers presented for reading at the monthly meetings of the Chemical Society, with the result that some of them are not read at all, and others are inadequately discussed. Furthermore, many Fellows are put to considerable inconvenience and expense in travelling to London to read their papers, and by increasing the number of localities where and occasions when papers can be read, delay in presentation and publication will be obviated, and a greater proportion of the contributions will be discussed and criticised. A paper, when read, may give rise to instructive and constructive criticism, valuable alike to author and audience, even if it be not sufficiently important to warrant subsequent publication; and the mere fact of public presentation would ensure, at any rate, a notice of the paper in the chemical scientific press, and perhaps also in the local newspapers.

From the point of view of our Local Sections it would appear that the reading of papers on pure chemistry would add to the attractiveness of meetings by providing a greater variety of subject matter. Those Sections which sometimes experience difficulty in filling their programmes would find relief in the greater quantity of material available, a consideration which applies more particularly to University towns; and other Sections which, owing to favourable environmental or other circumstances, have no such difficulty would reap the advantages of better attendances and wider publicity. In such cases it may be that the time devoted to the reading of each paper on the agenda would have to be curtailed, but many would regard this as an advantage; long papers are apt to become wearisome, and a free, fluent delivery of "things that matter" is preferable to reading verbatim, especially if an abstract has been circulated beforehand. Further, such composite gatherings would afford a common meeting-place for chemists of all classes and descriptions; readers of papers on technical chemistry would have the advantage of criticism by those who cultivate the "pure" science, and *vice versa;* and the opportunities afforded for social intercourse would be generally fruitful of much good, alike from the scientific, technical, and professional points of view.

But above and beyond all is the consideration that the whole-hearted adoption of the proposal would give impetus to the movement for securing that unity in the profession and practice of chemistry which many of us have so much at heart. The advantages accruing from co-operation and co-ordination have been dinned into our ears in recent years almost *ad nauseam*, and the time is surely ripe for action. Although the realisation of certain other proposals, such as that for a central Chemical House, may have to be postponed owing to the exceptionally adverse industrial conditions, there is much that can be done without delay. Bricks and mortar alone cannot make a united profession; it is the spirit that counts; and in the decision to extend to other chemists certain facilities which have hitherto been restricted to our own members, we see a manifestation of that desire for unity which alone can lead to the end we have in view.

DANGEROUS DRUGS.

Probably very few chemists see the pharmaceutical and medical press, and those who do are not likely to have read with care the articles which have appeared there recently on the draft regulations made by the Home Office under the Dangerous Drugs Act. These regulations are, however, likely to prove very detrimental to the interests of professional and research chemists. Thus Article 2 prohibits the manufacture of morphine, cocaine, ecgonine, or diamorphine, or their respective salts, or medicinal opium, except by persons properly licensed or authorised to do so, working on premises licensed for the purpose and in accordance with the conditions of such licence or authority. "Manufacture" is nowhere defined in the regulations, and it is a moot point whether a research chemist effecting a new synthesis of one of these alkaloids, or an analytical chemist determining morphine by extracting it from a plant or from the stomach contents of a poisoned animal, would not be "manufacturing" the alkaloid and so infringing the regulations, unless he takes the precaution to acquire a licence for himself and his premises.

Similarly in regard to Article 3, a chemist who effects a synthesis of one of these alkaloids or prepares one of them from a new source will be infringing the regulations if he sends some of his material to a colleague for confirmatory or supplementary tests, or even for inspection, unless he duly acquires a licence to supply the drug and acts in accordance with the terms of such licence or authority. But in this case not only is he himself likely to get into trouble, but the recipient may, unless duly licensed, be in the unfortunate position of having wrongfully secured possession of the alkaloid in question unless he, too, has taken the precaution to secure beforehand the necessary licence or authority. Experience gained hitherto in the working of the Cocaine Regulations shows that a long and tedious delay precedes the granting of a licence, so that a chemist requiring one of the so-called dangerous drugs may in future find that it takes many weeks to obtain even the smallest quantity of them. It also appears that a chemist who has acquired a supply of any of these drugs even for research or other professional purposes and has unwittingly left a grain or two in a bottle in some dusty corner of a stock-cupboard, or has

knowingly kept some for purposes of reference or comparison, will either have to destroy it or acquire a licence or other authority to retain it, and if he retains it he may apparently have to produce it when required for inspection by a constable or other duly accredited representative of the Home Office. As for purchasing, keeping and using these drugs for professional purposes, most chemists will think twice before undertaking to keep in order the licences, forms, books, etc., necessary to secure him immunity from the pains and penalties likely to overtake anyone undertaking such an operation.

These are a few of the possible difficulties which will occur to a chemist who casually peruses the draft regulations. The catalogue would no doubt be of considerable length if they were considered with a solicitor, versed in the possible legal twists and turns of an apparently innocent sentence in any of the 15 articles. Matters are apparently somewhat simpler if the chemist happens to be in addition a ship's captain with a ship at his disposal, a registered pharmacist, medical practitioner, dentist or veterinary surgeon; and the professional chemist who has much to do with these drugs, dangerous in more senses than one, will probably find his best course to be to take a medical degree, although even then he will probably need the help of a solicitor—unless he becomes that also—to steer clear of the difficulties which his professional duties may thrust upon him.

Fortunately the regulations are still only in draft, and it is earnestly to be hoped that the Institute of Chemistry and the Society of Public Analysts, which are the bodies best qualified to speak for chemists on such a matter, will promptly call the attention of the Home Office to a fact which it appears to have forgotten, namely, that professional, as well as legal, chemists, occasionally have to deal with these dangerous drugs in the course of their work. A short addition to the regulations indicating that chemists engaged in research, teaching or professional practice are exempt from the general restrictions would apparently meet the necessities of the case.

DISEASES OF OCCUPATION.*

STEPHEN MIALL.

The human body was designed for use in circumstances widely different from those which exist in modern industrial areas, and though evolution can accomplish much it is slow in its operation, and many thousands of years are required for any appreciable change in the qualities of the human organism. As chemical industry becomes more and more complicated it becomes more and more specialised, and we find now men and women who for the whole of their working life are engaged in the same processes, involving exposure to the same chemical compound hour after hour, day after day, and year after year. Whether this is entirely necessary I am not sure, but I wish to indicate very briefly some of the dangers of this sort of life and how they may be prevented or reduced to a minimum.

Broadly speaking, one may say that constant exposure to any chemical compound is likely to be injurious to health, particularly if the compound is likely to give rise to dust, fumes, or gas, and that an abundant supply of fresh air is, as one might expect, the best method of protecting the health of the workers. No doubt some compounds are worse than others, but one may say that all forms of dust and fumes are bad. Constant exposure to coal dust and tar causes what is known as pitch-makers' cancer, the tar being in this case the main irritant; the manufacture of marmalade causes injury to the skin by reason of the peeling of oranges and lemons; miners exposed to coal dust or to a fine silica dust have their lungs affected in a particular way; and workers exposed to dust of metallic compounds, phosphorus fumes, etc., contract specific kinds of poisoning.

Carbonic-oxide poisoning, carbon-dioxide poisoning, poisoning by chlorine, nitrous fumes, ammonia, aniline, tetrachlorethane, turpentine, ether, and acetone are not uncommon in industrial conditions.

The diagnosis of these diseases is often difficult, the cure is often difficult, the conditions under which they are contracted differ enormously, but they are usually all preventible by good ventilation.

The incidence of phosphorus poisoning is well known. Five-and-twenty years ago there were five or six cases a year in this country of phosphorus poisoning out of about 1700 persons employed in phosphorus processes. This has now been reduced to about three cases every two years, and the cause of the reduction is well known: to a large extent red phosphorus is employed instead of yellow phosphorus. The Swiss Government in 1879 introduced a Bill for the prohibition of the use of yellow phosphorus, which in due course became law, but it had to be radically altered because the disease became more prevalent. It seems that the workers imagined that when yellow phosphorus was prohibited they could dispense with a number of precautions which had usually been adopted, and they engaged to a considerable extent in processes where red phosphorus was used under very unhygienic conditions. Finally, the Act was practically repealed, and regulations were adopted by the various cantons which ensured suitable hygienic conditions of work. In France sesqui-sulphide of phosphorus, which gives off no fumes, has for many years been used instead of yellow phosphorus, and phosphorus poisoning has been stamped out in that country. It is interesting to note that whereas good ventilation and the ordinary rules of hygiene have in the main been responsible for the diminution of phosphorus poisoning in this and other countries, the substitution of some other forms of poisoning has been repeatedly advocated; in America there was a practice in match factories of hanging round the necks of the workers small vessels containing turpentine. In Italy a non-poisonous match was made of which the principal ingredient was persulphocyanic acid. The true remedy is a simple and efficacious one. Sir Thomas Oliver, who was a member of the Phosphorus Commission which reported rather more than 20 years ago, and is a recognised authority on dangerous trades, states in relation to phosphorus poisoning: "Of all hygienic measures full and free ventilation is the best."[1]

Cases of poisoning by carbon monoxide, nitrous fumes, ammonia, and other gases are on the increase in this country; there were 90 reported cases in 1913, and 132 cases in 1919; of these 59 in 1913 and 85 in 1919 were cases of carbonic oxide poisoning. Almost all these cases were due to ignorance on the part of the workers of the dangerous character of the fumes, or carelessness. There is no difficult chemical problem involved in the prevention of this form of poisoning; common sense in preventing and detecting leaks in flues will reduce such cases speedily, and workmen should be warned that products of combustion of all kinds are liable to be dangerous to health. A fair number of the cases of poisoning by such gases occur not in a closed room, but out of doors, in a gas works or lime kiln, or plant of that type. All these are preventible. In mines compressed air is largely used for drilling and for ventilation, and a number of deaths have

* From a paper read before the Liverpool Section on January 24, 1921.

resulted from the overheating of the air compressor and the firing of the oil used for lubricating the cylinders.[3] During the war there were many cases of carbon-monoxide poisoning from the exhaust of small power petrol-engines installed in dug-outs or similar places, and there have been cases of poisoning from the exhaust attached to closed motor cars, motor lorries, and ambulances.

During the last two or three years cases of chronic benzene poisoning have been notified in this country which have resulted from the employment of benzene as a solvent for rubber, and one case is of exceptional interest. In May, 1918, structural alterations were made in a particular factory, wooden uprights being inserted in certain windows so that they could not be widely opened. In July, 1918, a workman employed in the room was reported as suffering from benzene poisoning, and the case proved fatal.[3] Analyses of the air in different parts of the room showed from two to ten parts of benzene in 10,000 parts of air. The ventilation of the room was improved and no further cases occurred.

Poisoning by turpentine vapour is a problem which has been recently investigated in connexion with the paint industry. It has been long known that many persons are particularly susceptible to the smell of a newly-painted room; the white lead, the turpentine, the linseed oil, and the dryers have all been suspected. I suppose no scientific man now believes in a volatile lead compound given off as a gas or emanation from lead paint, and experiments made during the last twenty years clearly point to turpentine as being the delinquent. Lehmann in 1899 described the symptoms produced in cats by turpentine vapour, and Sir Kenneth Goadby has more recently shown that the poisonous effects produced in animals by exposing them to the vapour given off by painted surfaces are caused by the turpentine content of the paint and not by the linseed oil, dryers, or metallic salt of the paint. Turpentine poisoning produces kidney disease, and seems to cause, or predispose to, gout. Sir Kenneth Goadby states in the joint book by Dr. T. M. Legge and himself[4] that, according to Garrod, gout is constantly occurring among painters.

Dr. G. Arbour Stephens, in a recent paper,[5] reports that during the last six years he has had eight cases where the analysis of the liver showed from about 0·1 to about 0·9 grains of cadmium per pound, with merely a trace of lead. It is presumed from the details he gives that these cases occurred in the zinc-smelting industry in South Wales, and that they were all fatal cases. The symptoms of cadmium poisoning include kidney disease, constipation, and loss of appetite. Zinc is known to be a general protoplasmic poison and, according to Harnack, in the higher animals it causes muscular paralysis and kidney disease. Copper, tin, nickel, and manganese have injurious properties, but the cases of poisoning by these are few and far between.

White lead has been manufactured here since at least the time of Queen Elizabeth, and a variety of lead compounds has been made for a century; lead or lead compounds are used in a remarkably large number of industries and processes, and it is not surprising that by the time the disease had been identified and the method of preventing lead poisoning had become known it had become very prevalent; indeed, as we look back, it seems appalling to think that thirty years ago or less there were in Europe hundreds, or even thousands, of cases of lead poisoning every year, and most of them easily preventible. In many towns lead poisoning was in those days contracted through drinking water kept in contact with lead; in the white lead trade there were in this country nearly 400 cases a year; in the china and earthenware trade there were upwards of 200 cases a year; in smelting, in brass works, in printing, file cutting, glass cutting, shipbuilding and other trades there were over 400 cases, making a total of over 1000 cases per annum.

The attention of the public and of the Home Office was directed to the prevalence of lead poisoning at the end of the last century, when many inquiries were held and considerable information collected. The prohibition of the use of lead compounds in the pottery industry was threatened and various substitutes for lead were suggested. Finally regulations were put into force compelling the removal of dust, the wearing of overalls, regular medical examination, and so on. At the same time the manufacturers of china and earthenware were encouraged to use for glazing purposes an insoluble silicate of lead instead of the very soluble and very dusty white lead formerly used. On the whole the insoluble silicate has been a great boon to the manufacturers of pottery. It has been as satisfactory and cheap to use as the soluble white lead, more uniform in its composition and better to handle, and since its introduction the number of cases of lead poisoning in the china and earthenware trade has steadily declined. It came down from 200 a year in 1900 to 76 a year ten years ago, 15 cases in 1917, 11 cases in 1918 and 21 cases in 1919. The amount of lead in use in the industry has, so far as I am aware, not materially altered; the number of persons employed in the industry has slightly increased and the number of cases has declined to something less than one-tenth.

In the white-lead industry the diminution of cases has been somewhat similar, but even more marked: the number of cases was 399 in 1899, 189 in 1901, 40 in 1915, 18 in 1916, 17 in 1917 and none in 1918. The amount of white lead manufactured in England has declined during that period by about 10 per cent. and the number of persons employed is probably about the same as it was. These striking results have been attained by a careful study of lead poisoning during the last 20 or 25 years. Sir Edward Thorpe, Sir Thomas Oliver, and Dr. Legge, the Chief Medical Inspector of the Home Office, have been largely responsible for these results, and they were assisted in their efforts by a number of Home Secretaries, Inspectors of Factories and private individuals of both sexes. What is the vital factor necessary to the prevention of lead poisoning? Dr. Legge tells us in the Home Office Report for 1918,[7] and these are his words: "On the practical side little more is to be learnt as to how lead poisoning is caused, and it can be taken as axiomatic that all risk lies in inhalation of dust and fumes. These removed and prevented, there will be no lead poisoning." And again, in the Home Office Report for the year 1919,[8] Dr. Legge stated, "that locally applied exhaust ventilation is the sheet-anchor in the protection of the workers from leady dust and fumes and that these alone are the causative agents." With this knowledge it should be possible to reduce yet further the cases of lead poisoning in this country, and the next trade in which a serious effort is to be made is the painters' trade—I mean the painting of houses, ships, bridges and so forth, not the manufacture of paints and varnishes.

It is somewhat unexpected that lead poisoning should be caused not by the particles of lead swallowed by the worker, but by even more minute particles of lead compounds floating in the air and getting into his lungs and there acted on by the juices of the body and so getting into the system. But that this is the usual cause is now generally accepted.

The problem is beset with small difficulties which nevertheless are capable of being surmounted. To begin with, lead poisoning is in many cases by no means easy to identify. A doctor who regularly examines men who are employed in a lead factory

can, with a good deal of certainty, state whether a particular man is contracting lead poisoning and should be suspended from work or given employment which does not involve contact with lead compounds. But if a worker goes to the average careful general practitioner and complains of headache, colic, constipation, kidney trouble, and so on, it is pretty nearly impossible for the cause of these symptoms to be identified. There are so many things which will bring about these symptoms. Legge and Goadby—and I quote these as the greatest living authorities on lead poisoning—state in their book[9]: "The headache complained of by painters is probably not due to lead poisoning but, as has been suggested, to turpentine." Turpentine, too, is probably the cause of the gout to which painters are subject. But of one thing we may be certain, if a man goes to a general practitioner and complains of such symptoms as I have mentioned, and states that he is a painter or employed in a lead works, his case will be duly reported as one of lead poisoning. This is not merely an opinion of my own. Legge and Goadby[10] say that there is "an increasing inclination to attribute chronic nephritis and even (without sufficient justification in our opinion) phthisis and pneumonia to lead poisoning on the death certificates of lead workers." I do not deny that lead poisoning exists among painters and others, but I am quite certain that a great many of the so-called cases of lead poisoning in the paint trade and in other trades have no connexion with lead at all. The cases of cadmium poisoning I have already mentioned were some of them certainly, and all of them probably, returned in the statistics as lead poisoning, and no one can say how many cases of turpentine poisoning, indigestion, Bright's disease, etc., among lead workers have been returned as lead poisoning, but the number must be very large.

From time to time proposals have been made to reduce the frequency of lead poisoning by prohibiting the use of white lead in paint, and this question will be considered at the next conference of the International Labour Office at Geneva. I want you as scientific men to consider somewhat carefully what such prohibition means; if the principle is once admitted, we may have to face the prohibition in their own industries of mercury, antimony, copper, arsenic, and a host of other chemicals which are not intended for human consumption. The prohibition of lead in paints only deals with a portion of the problem, and will give a false sense of security to the painters similar to that which operated so dangerously in the phosphorus workers in Switzerland. The proper solution of the problem is that which has been found so efficacious in many other diseases of occupation—fresh air and the removal of dust and fumes. It has been seriously advocated that to avoid lead poisoning houses should be painted with antimony compounds, titanium compounds, and other heavy metal derivatives; the fact is that the dust of nearly all compounds of heavy metals is injurious and that the fumes of nearly all volatile solvents are bad for the health.

It is known to all in the trade that the dust is produced in the dry rubbing-down of old paint by pumice-stone or sandpaper, and, in my opinion, this should be prohibited by law. Rubbing down can be done wet—perhaps not quite so easily, but sufficiently so—and the painters ought to be protected from exposure to dust of old paint.

It is possible to do away with the dust of the rubbing down by keeping the sandpaper moistened with a cheap mineral oil. The sandpaper lasts as well as without the oil and the result upon the paint is fully as good. This is a method with which many German painters are familiar, and if it could be generally introduced into this country a great step forward would have been taken in improving the conditions in house painting and carriage and railway coach painting and ship painting.

Again, there is no reason why painters and those who prepare the paints for them should ever handle or be supplied with dry white lead or any other pigment; these should invariably be supplied ground in oil or some other medium. As to the vapours from the solvents in ready-mixed paints, I saw workmen in America a year or so ago painting the inside of a house by means of a spray, and attached to the painter was a tube communicating with the outside of the house enabling him to breathe fresh air instead of air which, in that particular case, was contaminated by the vapours of benzene, white spirit, and other solvents. If this method of applying paint is not liked in this country, much might be done by the opening of doors and windows of a newly painted room. The question of individual susceptibility has also to be considered, but one may say with a good deal of confidence that the prevention of dust, or its removal by fans or otherwise at the moment of its formation, and the removal of vapours or volatile solvents and the substitution of fresh air will bring cases of painters' colic, whether properly attributed to lead, to turpentine, or any other substance, down to insignificant proportions, and that no other remedy will be equally efficacious.

I am sorry to say that this sort of reasoning does not appeal to such a body as the International Labour Office, and that the very polyglot body which will in due course meet at Geneva will pay but little attention to medical evidence. The Treaty of Peace signed at Versailles provided for the holding of international conferences on questions in which labour is interested, such conferences to be attended by representatives of the governments, the employers, and the workers of every country, and each country is under an obligation to carry out so far as practicable the decisions arrived at by the conferences.

When I was at Washington rather more than a year ago at the first of these conferences we had to consider the health of the workers, and, in particular, the prevention of anthrax, of mercury poisoning, of phosphorus poisoning, and of lead poisoning in so far as it affected women and young persons. We made certain recommendations, one of which has in substance been embodied in the Women and Young Persons (Employment in Lead Processes) Bill, which became an Act of Parliament last session. I am bound to say that though I have in the past had a good deal to do with Acts of Parliament, I did not realise until I was at Washington the extraordinary difficulty of devising rules which would achieve the desired result without unnecessary dislocation of trade, and which were capable of being applied to a variety of countries with different industrial conditions and different methods of domestic legislation. With my recent experience of the Lead Processes Bill, I now realise the difficulties still more acutely, but even at Washington I thought it desirable to suggest to the conference that in view of the complexity of industrial diseases the problems attached to them should be carefully considered beforehand by a committee on which the governments, the employers, and the workers should all be represented. The Conference at Washington unanimously recommended the appointment of such a committee, but no such committee has been so far appointed, and a purely bureaucratic organisation is tackling the problems instead. Governments are particularly susceptible to public opinion, and the public opinion of to-day is largely based on the imperfect recollection of the cases of lead poisoning which occurred five-and-twenty years ago. An instance of this was brought to my notice during the passage of the above-mentioned Bill through

Parliament last session. In supporting the Bill one speaker gave an instance of lead poisoning which had occurred in the paint trade. He gave various details, and I had the incident he mentioned looked into and found it was a case of poisoning by arsenite of copper. This is typical of what happens. The conditions five-and-twenty years ago were so bad, and made such an impression on the social workers of the day, that many people believe that they prevail yet. The fact is that the Home Office, under the guidance of Dr. Legge, has very much reduced lead poisoning, and in the pottery industry has to all intents and purposes abolished it, for there are in that trade no new cases, and the cases which are from time to time reported in the china and earthenware statistics are the deaths of workers as they gradually get old, who contracted lead poisoning many years ago, before the Home Office regulations came into force. But though these facts are known to a few of us, the public as a whole, not only in this country, but in other countries, have not had time to bring their knowledge up to date, and, stimulated by their recollection of bygone days, they have brought pressure to bear on the various governments of the world, and the officials who represent them, to treat the problem as if it still was in the same state as it was a generation ago. The International Labour Office shows no inclination to have such problems scientifically examined by the employers and workers who are most nearly concerned, but they have appointed a permanent official, who seems to be entrusted with the duty of preparing a case for the prohibition of lead, and who has manifested no anxiety to have the assistance of such a committee as was recommended at Washington.

It is not very easy, but it is possible, to frame regulations which would reduce to a minimum the vapours and dust to which painters are exposed, and you may ask me why such regulations have not been, at any rate, given a trial. The answer is that in some foreign countries—for instance, Austria, Germany, and Belgium—they have been tried and have proved beneficial, and I am not without hope that the Home Government may give them a trial. Government Departments at the present time have their hands full of problems, and one cannot blame any department for not desiring to add more to its already heavy load. But I think the Home Office must pay the penalty of success. It has done so much to improve the condition of the workers with so little interference with trade; it has in the past co-operated fairly and reasonably with trades unions and manufacturers, and the tradition which it has created is one not to be lightly destroyed. We chemical manufacturers and chemists, recognising the importance of chemistry to the nation and the fact that we are now only in the beginning of a highly specialised chemical industry, must bring pressure to bear on the Home Office and all other Government Departments concerned to maintain the high standard they have themselves set up and not to be led away by the false gods of the Geneva bureaucracy. The International Labour Office may be productive of much good, but in so far as industrial hygiene is concerned it will accomplish nothing without the co-operation of those primarily affected, and its present methods are tending to promote suspicion rather than confidence.

BRITISH CHEMICAL PLANT MANUFACTURERS' ASSOCIATION.

Prior to the war British chemical manufacturers procured much of their plant from Germany owing to the difficulty they experienced in obtaining plant in this country which satisfied their requirements. A feeling had long prevailed in the industry that steps should be taken to promote closer co-operation between British chemical and British chemical-plant manufacturers. The need for such action was fully realised by those members of the Association of British Chemical Manufacturers who accompanied the mission sent out by that body under the ægis of the Department of Overseas Trade to inspect chemical factories in the Occupied Area of Germany in May, 1919.

A year later it was decided to invite representatives of the plant manufacturers to meet in conference representatives of the Fine Chemical Group of the Association of British Chemical Manufacturers, to whom the matter was of particular importance. The plant manufacturers agreed that it was desirable that they should be brought more closely into touch with the chemical manufacturers and kept more adequately informed of their requirements, and expressed their willingness to do all in their power to assist the chemical manufacturers. The two conferences then held led to the formation of the British Chemical Plant Manufacturers' Association, which at its inaugural meeting in July last consisted of nineteen firms. Mr. J. H. Rawson (The Widnes Foundry Co., Ltd.), Mr. L. M. G. Fraser (Messrs. W. J. Fraser and Co., Ltd.), and Mr. E. A. Alliott (Messrs. Manlove Alliott and Co., Ltd.) were elected chairman, vice-chairman, and hon. treasurer, respectively, and Mr. W. J. U. Woolcock (General Manager of the Association of British Chemical Manufacturers), secretary. The new Association became affiliated to the Association of British Chemical Manufacturers.

It was agreed that one of the first questions to be considered was the standardisation of chemical plant and apparatus, in which the Germans have reached a very advanced stage. At a joint meeting of representatives of the two Associations it was decided that the question of standardising jacketted-pans with stirrers and covers, boiling-pans and filter-press plant should be the first to receive consideration. The joint sub-committees which were set up to consider these matters are making good progress. Both the British Chemical Plant Manufacturers' Association and the Association of British Chemical Manufacturers are represented on the Sectional Committee on Chemical Engineering of the British Engineering Standards Association, which is also considering the standardisation of chemical plant and apparatus. A joint research committee was also appointed to investigate any new types of plant which may be reported to be in use in other countries and to go into any questions bearing upon the improvement of chemical plant in this country. This committee has invited the co-operation of the Chemical Engineering Group of the Society of Chemical Industry.

Attention having been drawn to the fact that the German plant manufacturers utilise nickel to a much greater extent than the British plant manufacturers, the Committee has now under consideration the uses to which this metal could be put in chemical plant. In this connexion very valuable assistance is being received from the Mond Nickel Co. The question of the use of 12 per cent. chromium steel is also being investigated.

The membership of the British Chemical Plant Manufacturers' Association has increased considerably since its inauguration, and it is hoped that, as the Association becomes more fully representative

of the various branches of the manufacture of chemical plant, the object for which is was formed will be achieved, namely, to ensure that British chemicals shall be made with British plant.

THE HABER PROCESS AT MERSEBURG (SAXONY).

J. R. PARTINGTON.

The Haber process carried out at Merseburg differs from that at Oppau (cf. J., 1921, 99 R) in two respects:—(i) The mixture of nitrogen and hydrogen is made directly by treating a mixture of producer (air) gas and water gas, with the addition of steam, by the Bosch process (B.P. 14,508 of 1920); (ii) the purified mixture of nitrogen and hydrogen, before passing to the main catalyst furnaces, is passed through a series of small catalyst furnaces ("Vorofen") to remove impurities (B.P. 5835 of 1911).

There are 31 gas generators, 5 for air gas and the rest for water gas, all the air being provided by two blowers, each of 350 h.-p. The gases are passed through three gasholders, each of 1,765,000 cb. ft. capacity, providing a reserve for fifteen minutes. From these the gases are taken and mixed by blowers. The mixed gas then takes up the requisite amount of water vapour in two rows of six towers, each 82 ft. high, through which hot water is pumped by seven pumps, each of 70 h.-p. The water is warmed in a tower by the gases leaving the heat-exchanger of the contact furnaces for the hydrogen production. There are 48 heat-exchanger towers.

The gases, containing hydrogen, nitrogen, carbon monoxide and some carbon dioxide, now pass, after preheating, to two sets of 24 contact furnaces in which the reaction $CO+H_2O\rightleftarrows CO_2+H_2$ occurs. The gas passes to two gasholders, one of 350,000 cb. ft. and the other of 1,050,000 cb. ft. capacity. Carbon dioxide is removed by washing in 21 to 30 towers at 25 atm., the compression of the gas being in large part effected by one of the cylinders of the 200 atm.-compressors, although a few pumps for 25 atm. are provided. Pelton wheels recover about 40 per cent. of the energy of the released gas, which is utilised to compress the water to 25 atm. The power for this part of the plant is 40,000 h.-p.

For the removal of the carbon monoxide, the gas compressed to 200 atm. by twenty-four 1000 h.-p. compressors and twelve 500 h.-p. compressors is scrubbed in 19 towers with ammoniacal copper formate solution circulated by nine double pumps of 600 h.-p. The carbon monoxide recovered by reducing the pressure in the towers is sent along with water to the hydrogen contact-plant. Six towers for caustic soda remove the remaining carbon monoxide, the soda being circulated by six small pumps.

The gas now passes to nine small contact furnaces ("Vorofen"), in which the remaining impurities are removed by catalyst mass before passing to the main contact furnaces. There are twenty-four main catalyst furnaces, five being in reserve, and twenty-four heat-exchangers. Circulation is effected by eleven pumps of 700 h.-p. each ("Umlaufpumpen"). The ammonia formed is absorbed in water, compressed to 200 atm. by five 100 h.-p. and two 300 h.-p. pumps in twenty towers 39·3 ft. high and 29 ins. diameter. The ammonia solution is passed to an expander, the ammonia gas evolved being absorbed in a separate tower. In the expansion the hydrogen and nitrogen gases dissolved in the water under 200 atm. pressure are liberated; these pass through the ammonia scrubbing tower and are collected in a gasholder, from which they re-enter the circulatory system.

The capacity of the Merseburg factory, when completed, will be 800 tons of ammonia per day.

SOCIETY OF CHEMICAL INDUSTRY.

APRIL MEETING OF COUNCIL.

Among the matters considered at the meeting held on April 15, Sir William J. Pope presiding, was a suggestion made by the Institution of Mechanical Engineers that a further joint meeting of the two societies might be held in the early part of next session. The Institution proposed that the paper should be contributed by one of its members, and should deal with some subject of common interest, such as the construction and manufacture of large-scale chemical plant. The suggestion was cordially approved. The proposal put forward by the Chemical Society is dealt with elsewhere in this issue (p. 139 R).

Sir William Pearce was re-appointed the Society's representative on the Governing Body of the Imperial College of Science and Technology for a period of four years from June 1 next; and the resignation from the Council of Mr. W. J. A. Butterfield on account of pressure of work was accepted with regret. It was reported that the following retire from the Council after the Annual General Meeting:—(*a*) Vice-presidents: Prof. W. R. Hodgkinson, Mr. Robert Mond, and Mr. W. F. Reid. Mr. S. R. Trotman also retires but is eligible for re-election. (*b*) Ordinary members: Mr. C. S. Garland, Sir R. Hadfield, and Dr. F. M. Perkin.

The Government and Parliamentary Committee reported that it had brought before the Board of Trade certain points in the Dangerous Drugs Act, 1920, which may prevent or restrict the development of scientific research in the particular chemicals to which the Act refers. The renewal of the Society's subscription to the Conjoint Board was authorised. Twenty-eight new members were elected; and the report of the Manchester Section was submitted and approved.

ANNUAL MEETING, 1921.

McGILL UNIVERSITY, MONTREAL.

It will be of particular interest to members who are going to Canada to attend the annual meeting of the Society in August, to know that many of the members they will meet there as manufacturers, or associated with manufacturers, are graduates of the university which owes its existence to the exceptional foresight of the Scotchman James McGill, who was born in Glasgow in October, 1744. Exactly one hundred years ago, in 1821, the charter for the establishment of McGill University was granted.

When the visiting members first see the University they will find it difficult to realise that the fine site the University buildings occupy in the heart of Montreal was wild pasture land less than a century ago. But the rapidity of development characteristic of Canada is exemplified in this seat of learning as well as in commerce, manufacturing, and agriculture, and an idea of the vast strides that have been made may be gathered from the fact that when James McGill was one of Montreal's leading merchants the town consisted of only 9000 people, whereas the city's population is now approaching one million. Prominent among the buildings is that of the medical faculty, which brings to mind some of the men most famous in

medical science. McGill University has given to the mother country two of her most illustrious professors, Sir W. Osler and Sir E. Rutherford.

Associated with the University are the Forest Products Laboratories of the Dominion Government, the function of which is research and technical service relating to woods and all products derived therefrom. The fact that Canada is the third largest timber-producing country in the world and the largest within the Empire indicates the importance of this work. Canada was the first country in the Empire to establish laboratories of this kind, but the value of research in connexion with forest products is now recognised, and similar institutions have been or are being established in India, in Australia, Great Britain, and Burma. The laboratories at present are organised into four research and technical service divisions, namely, pulp and paper, timber, physics, timber tests, and wood preservation. Visitors interested in work of this kind will be made welcome and conducted through the institution by a member of the staff.

* * * * *

Members and their friends who propose to attend the Annual Meeting in Montreal and/or the subsequent proceedings in Canada and the United States are reminded that they will be heartily welcome to travel with the President and his party by the s.s. "Megantic," which leaves Liverpool for Montreal on August 12; and that they should notify the General Secretary of their intention without delay.

NEWS FROM THE SECTIONS.

NOTTINGHAM.

At a meeting held on April 13, Mr. S. H. Burford gave an informal account of the work of the Public Analyst. The variety and amount of the information required concerning each sample have much increased in recent times. An analyst must be a student all his life; he must have a wide knowledge of the chemical and legal sides of his profession, and must be able to prepare reasoned and judicial reports. Mr. Burford suggested that the time was ripe for the institution of official laboratories throughout the country, staffed by full-time assistants, and each in charge of an expert who should deal with special substances, *e.g.*, water and sewage in one laboratory, oils and fats in another.

The chairman, Mr. J. H. Dunford, noted that under the Fertilisers Act it might be an offence to sell a product having a higher percentage than that demanded by the Act. Mr. J. White considered that the cares and variety of the work lent it interest. Milk which was clean when first produced should be kept so, not contaminated and then purified. Major S. R. Trotman agreed as to the exacting work of the profession. The analyst had little or no time for research into analytical methods. Mr. H. Droop Richmond said that the analyst, as a consultant, was kept in touch with analytical problems, and he simply had to make time to investigate them. Mr. S. J. Pentecost thought that the results of the Public Analyst should be made available to the public as were those of Medical Officers of Health. Mr. J. M. Wilkie referred to a recent paper by Cofman on the French system of territorial laboratories; and expressed the opinion that the Public Analyst should be better remunerated so that he might have a proper staff. Mr. Burford, in reply, and also Mr. H. Droop Richmond, remarked upon the uniformity of milk samples at the present day, which they ascribed to the elimination of the small dealer, or the blending of small supplies, or the control by analysts employed by large firms.

MEETINGS OF OTHER SOCIETIES.

FARADAY AND OTHER SOCIETIES.

A general discussion, organised by the Faraday Society with the co-operation of several of the technical societies, was held on April 6 in the hall of the Institution of Mechanical Engineers, the subject being "The Failure of Metals under Internal and Prolonged Stress." As nearly all of the 17 papers presented had been printed and circulated beforehand, it was possible to confine the actual presentation of the papers to a few minutes, leaving for the discussions the greater part of the six hours occupied by the three sessions into which the meeting was divided. This arrangement was found to be very successful, and the subject was treated from many points of view, metallurgists, engineers, and pure physicists contributing their quota of information and opinion. Prof. A. W. Porter, Capt. H. Riall Sankey, and Sir George Goodwin, as presidents of three of the co-operating societies, presided in turn.

Dr. W. Rosenhain, in an introductory address, explained how the hypothesis of an inter-crystalline cement had been developed to account for the phenomena of the time-effect in the flow of metals under stress and the spontaneous cracking of cold-worked material. This hypothesis received strong support from Sir Alfred Ewing, speaking from the standpoint of the crystallographer, and it must be said that, although numerous objections to the hypothesis from the theoretical and practical sides were brought forward, no other hypothesis capable of explaining the whole of the facts was suggested. In the discussion of the general question much stress was laid on the part played by corrosion in the initiation of season-cracking, the important investigations of Mr. H. Moore and his colleagues in the Research Laboratory of Woolwich Arsenal containing evidence, derived from a large quantity of experimental material, that such cracking only occurs when chemical action has taken place. Some speakers considered that cracking also occurred in the absence of chemical action, but such a statement is naturally difficult to prove, since minute traces of ammonia, for instance, are sufficient to initiate the action. Prof. C. H. Desch reviewed the facts concerning the inter-crystalline nature of the attack of certain chemical reagents on various metals and alloys, and laid stress on the selective action in such cases. Evidence of the effect of time in bringing about fracture under comparatively low stresses was afforded by Mr. L. Archbutt's observations on the failure of the lead sheathing of telegraph cables, the metal showing inter-crystalline brittleness without chemical corrosion. Dr. W. H. Hatfield's paper opposed the hypothesis of an amorphous film, continuing a controversy begun at a recent meeting of the Institute of Metals.

After the general papers, two groups of papers dealing respectively with steel and with the brasses and similar alloys were taken. Sir Henry Fowler described the failure of some steel locomotive boiler tubes, and several speakers dealt with the remarkable brittleness in steel caused by the action of hot solutions of alkalis and certain salts. Cases of inter-crystalline failure in steel are comparatively rare, but have a special interest. The season-cracking of brass was dealt with from several aspects, much experience having been gained during the war in regard to the behaviour of brass tubes, cartridge cases, and other objects. There were several contributions from Woolwich Arsenal on this subject, and it was shown that the method recommended there and adopted by some manufacturers of annealing at a temperature too low to cause softening of the hard-worked metal

is an effectual preventive of season-cracking. It was stated, however, by some speakers that when a correct draft is taken in the drawing of tubes, for instance, the setting up of severe internal stresses is avoided, and annealing becomes unnecessary. The almost explosive cracking of hardened steels was discussed, a paper on this subject by Mr. J. N. Greenwood entering deeply into the theory as well as the practical experience in hardening shops.

The joint discussion must be considered as one of the most valuable of those which have been held under the auspices of the Faraday Society, and the interchange of views has done much to prepare the way for a comprehensive survey of the whole subject of failure under stresses of the kind which present themselves in season-cracking, slowly developing brittleness, and other forms of intercrystalline weakness.

NATIONAL UNION OF SCIENTIFIC WORKERS.

The half-yearly meeting of the Council was held on April 9, in London, the president, Prof. L. Bairstow, presiding. Among the resolutions passed unanimously were the following:—

"That this Council views with misgiving the subordination of scientific workers controlling scientific staffs to non-scientific officials in Government departments. It considers that it is in the best interests of the State that its scientific officers should enjoy the greatest possible freedom from lay interference in connexion with their duties, and should be granted at least equal status and remuneration to that of officials of the highest class in the Civil Service."

"That this Council, having regard to the existing demand for increased educational facilities, deplores the growing tendency of public bodies to reduce expenditure on education, particularly in neglecting to provide for further institutions for the study of science and technology, and by threatening existing institutions with closure, irrespective of their national utility."

A third resolution deprecated the tendency to discriminate between the sexes in the payment of salaries of scientific workers; a fourth urged freedom in research and the undesirability of research work demanding privacy in its pursuit and restriction in publication being undertaken under the auspices of a university; and other resolutions were carried approving the appointment of a consultative committee of representatives of Government branches, and of allowing reduced subscriptions to members resident abroad and to research students and apprentices receiving small grants or salaries.

On April 14 Mr. H. E. Potts, of Liverpool, addressed the London Branch on "The Position of Employer and Scientific Worker in relation to Patent Law." Prof. L. Bairstow presided.

Mr. Potts dealt with the present legal position, the basic principle of which is that in the absence of special contract the invention of an employee, even though made in the time, with the materials, and at the expense of the employer, does not become the property of the employer so as to prevent the employee from taking out a patent. There are, however, many exceptions, and the higher the position of the employee the more likely they are to apply. The four principal exceptions are:—(1) The work may be done under specific instructions, in which case the director may claim to be the inventor and his claim allowed. (2) The work may be considered as a condition of employment and to be included in the duties of the position held. (3) The worker may be in a position of special confidence and have access to special information. The case quoted was that of an English agent for an American firm who attempted to patent in England an improvement on the firm's design. (4) There is frequently an agreement in force between firms and their scientific staffs that all patents arising out of work done shall be assigned to the firm. In return some firms give bonuses for successful inventions, others a share of the proceeds or royalties, and it sometimes happens that a firm only claims a free licence and leaves all royalties to the inventor. Mr. Potts is of the opinion that the Union should decide what is a fair agreement, and that some form of bonus for successful inventions should be offered to stimulate effort in the final stages of invention. He suggested that before formulating a policy in regard to inventions of scientific workers in industry, the Union should investigate the conditions prevailing in America and on the Continent, and should confer with some representative body of employers.

ROYAL PHOTOGRAPHIC SOCIETY.

The meeting held on April 12, arranged by the Scientific and Technical Group, was devoted to a consideration of some aspects of kinematography. Mr. R. J. Trump described an ingenious device for a shutterless, continuous-feed, projecting kinematograph. The light from the projecting lens is reflected by a plane stationary mirror on to the inner periphery of a large wheel rotating synchronously with the movement of the film. The wheel carries a number of plane mirrors arranged in sets of three and disposed at such angles that the image of the moving picture is kept stationary on the screen. An absence of flicker and a reduction of wear and tear of film and mechanism are the advantages claimed for the system.

Mr. H. M. Lomas dealt generally with the limitations imposed by the materials at present available for kinematographic purposes and the difficulties arising from them. Amongst the things specifically mentioned were "static markings," marks produced in the unwinding of the film caused by light flashes due to electrification, and the coarseness of grain of the emulsion which limits definitely the amount of magnification allowable.

THE PHYSICAL SOCIETY.

At the meeting held on April 8, Sir W. H. Bragg read a paper on "The Application of the Ionisation Spectrometer to the Determination of the Structure of Minute Crystals." The method of X-ray analysis of the structure of minute crystals as developed by Debye and Hull necessitates the use of heavy discharges in the X-ray bulb and long exposure of the photographic plate. In the present method, the crystal powder is pasted on a flat surface and placed on the spectrometer table in the manner employed for a large single crystal. The intensity of the diffracted X-ray spectrum corresponding to various angles is measured in the ionisation chamber of the spectrometer in the usual manner. A bulb current of one milliampère is sufficient, and the main part of the spectrum can be determined in about half an hour. The paper was illustrated by the spectra of aluminium, silicon, and lithium fluoride determined in this manner.

A paper on "A New Registering Microphotometer" was submitted by Dr. W. J. H. Moll, of Utrecht. The instrument is designed to record the respective densities of very small areas of a photographic plate. A small incandescent lamp is fitted with a condenser, whereby an image of the glowing filament is cast upon a slit. The photographic plate is disposed between two microscope objectives in such manner that an enlarged image of the illuminated portion of the plate is produced at a second slit through which radiation transmitted by the

plate passes and falls upon an extremely sensitive and robust type of thermopile designed by the author. The plate can be given a slow motion by a micrometer screw, and the beam of light reflected from the mirror of the galvanometer connected with the thermopile records the intensity of the radiation transmitted by the illumined portion of the plate. The device is readily applicable to the investigation of the density of photographic negatives of all kinds, and the extremely sensitive thermopile employed should find application in a large number of other directions.

ROYAL SOCIETY OF ARTS.

A paper on "Low Temperature Carbonisation and Smokeless Fuel" was read by Prof. H. E. Armstrong on April 13, Sir Arthur Duckham presiding.

In the first part of his paper, Prof. Armstrong dealt with the use and abuse of coal as fuel, and outlined the early history of "coalite." Early in 1913 a large German company was about to associate itself with the English undertaking, but the war intervened, and it was not until 1919 that development work was resumed at Barnsley. A carbonising plant built to the design of Mr. T. M. Davidson had been in operation since November, 1920, and was undoubtedly a success. The trouble due to expansion of the fuel on carbonisation had been overcome by building the ovens with upright walls and fitting them with perforated hanging plates movable in a vertical plane over a narrow range; the coal was filled into the space between the side of the oven and the opposed face of each plate, thus enabling the width to be varied. During carbonisation the plates exerted pressure on the coal, and the volatile matter escaped through the perforations. When carbonisation was complete, after 5—8 hours, the "coalite" slabs were allowed to fall into an air-tight, water-cooled chamber. It was essential that the "coalite" should not be exposed to air during cooling. The product contained 10—15 per cent. of volatile matter and burned with a bright flame; the coal oil was well within the Admiralty specification for fuel oils; and motor spirit could be obtained from the liquid and scrubbed from the gas.

In the long discussion which followed, the chairman said that he had seen the plant at Barnsley and was convinced of its success. The great drawback to the process, however, was the lack of an absolutely satisfactory balance-sheet, and this was the reason why gas engineers had fought shy of it; the success of the process would depend on the value of the "coalite" and the value of the oil. Dr. J. A. Harker said that in an investigation carried out under the auspices of the Ministry of Munitions, it was ascertained that from 1 ton of coal the yield of crude "coalite" was 14 cwt., of which rather less than 13 cwt. was saleable. Economically, the process depended upon selling the 13 cwt. for the same price as that paid for 1 ton of the coal, and of paying operating costs from the sale of by-products. He thought that the margin between profit and loss would be very narrow. Among the points raised by subsequent speakers were the friability of fuel produced by low-temperature carbonisation processes and the necessity for briquetting, the economy that should be obtainable with the Neilsen process of internal-heating of the retorts with water gas, and the need of eliminating as much ash as possible by properly washing the coal.

In his reply, Prof. Armstrong said that, as a professor, he was not concerned with the cost of the process. The public should be prepared to pay more for "coalite" than for coal because it did not burn away so rapidly and was smokeless. The yield of fuel oil was about 1 ton from 10 tons of coal.

THE CHEMICAL SOCIETY.

A meeting was held at the Institution of Mechanical Engineers on April 7, Sir William Pope presiding, when Dr. F. W. Aston delivered a lecture on "Mass Spectra and Atomic Weights." On April 21 an ordinary scientific meeting was held at Burlington House. Sir James Walker, the new president, gave a short address, and then six of the nine papers on the agenda were presented in abstract. The paper of most immediate interest to technical chemists was that by Dr. J. A. Newton Friend on "A Colloid Theory of the Corrosion and Passivity of Iron and of Ferrous Salts," of which the object was to show that the reactions involved are not purely ionic but colloidal.

When iron is exposed to moving water containing dissolved air the rate of corrosion increases rapidly with the flow of the water until it reaches a maximum, after which further increase in the velocity of the water causes a retardation of corrosion, none taking place at about five miles per hour. It was suggested that iron slowly oxidises in aerated water to form colloidal ferrous hydroxide, which then undergoes alternate oxidation by air and reduction in contact with metallic iron, the latter suffering rapid corrosion. If, however, the colloid is swept from the surface of the iron as rapidly as it is formed this autocatalytic action cannot take place, and the iron oxidises but slowly. The theory was tested by determining whether or not the rate of corrosion is influenced by factors that increase the stability or effect the precipitation of positive sols. This was shown to be the case. Thus the presence of anions such as Cl, SO_4, and Cr_2O_7 is known to cause the precipitation of colloidal iron hydroxide, Cl being least and Cr_2O_7 most effective. These ions also influence the rate of corrosion, Cr_2O_7 exerting the most marked inhibiting action and Cl the least. It was also shown that protective colloids, such as gelatin, acacia, and albumin, inhibit corrosion, and that there was a remarkably close relationship between their action in this respect and their influence on the catalytic activity of colloidal platinum upon hydrogen peroxide. Suspensoid colloids are very sensitive to "poisons," and attention was drawn to the fact that poisons also inhibit corrosion, arsenious oxide being particularly effective. Radium rays, which precipitate iron hydroxide sol, likewise retard corrosion. Colloidal iron hydroxide is very stable in pure water, and is not precipitated by boiling. Addition of small quantities of an electrolyte, such as sodium chloride, causes marked precipitation if the temperature is raised. An explanation is thus forthcoming of the remarkable and otherwise inexplicable fact that whereas sea-water is more corrosive than fresh water at 10° C., it is less corrosive at 30° C. It was pointed out that passivifying agents are those which possess anions capable of precipitating positive sols; and the oxidation of ferrous sulphate in neutral or alkaline solution was attributed to the presence of a sol.

Dr. F. Challenger contributed a paper on the interaction of the halogen derivatives of tertiary aromatic bismuthines with organo-derivatives of magnesium and mercury; Prof. G. T. Morgan outlined some new work by himself and Mr. J. D. Smith on the constitution of simple and complex cobaltic quinoneoxime lakes; and Dr. N. V. Sidgwick and collaborators presented three papers dealing with the influence of position on the solubility of the substituted benzoic acids, on the solubility and volatility of the mono- and dinitrophenols, and on the solubility and volatility of the chloro- and nitro-anilines and their acetyl derivatives.

NEWS AND NOTES.

AUSTRALIA.

Cobalt Ore in Queensland.—The Imperial Mineral Resources Bureau has received from the Department of Mines, Brisbane, an account of the development work which has been carried out on the recently discovered deposit of cobalt ore in the Cloncurry district (*cf.* J., 1920, 378 R). Two shafts, 250 ft. apart, have been sunk on the general strike (underlie), the first to a depth of 112 ft. and the second to 92 ft. In No. 1 shaft from the surface to 42 ft. the ore (cobaltite) averaged 4—5 per cent. metallic cobalt over an average width of 5 ft. A similar ore body was found at 80 ft. No. 2 shaft has met with ore varying from 1 to 3 ft. wide of similar value to that encountered in No. 1 shaft. Development work is not sufficiently advanced to show if the ore occurs in short shoots or as a continuous run.

Shale Oil in New South Wales.—The Joadja oil-shale mine, which was formerly worked by the Australian Kerosene Oil and Mineral Co. but closed down about 20 years ago as a result of American competition in oil, is now being reopened by the Shale Petrol Oil Co., Ltd., a new company that proposes to work the coal, which occurs abundantly on its property, as well as the shale. The mine is situated near Mittagong, on the main line between Sydney and Melbourne. On distillation, the shale gives 73 per cent. of volatile hydrocarbons and an average of 106 galls. of crude oil per ton of shale. The old company produced considerable quantities of motor spirit, which in those days was considered a nuisance and therefore burnt on the spot.

Tasmania.

Shale Oil Distillation.—The Rialton-Latrobe shale works has started to send crude oil to Melbourne to be refined. The company owns shale deposits which are expected to produce about 300 million galls. of oil, and is installing a plant which should be able to distil about 350 tons of shale per day. Demand for oil is growing almost daily, owing to the steady increase in the use of motors for farming operations.

Cement Manufacture.—The hydro-electric plants which are being laid down in Tasmania are making very heavy demands upon the supplies of cement available in the island. As a result of this, new cement works are being erected by the National Portland Cement Co. on Maria Island, and by the Fingal Cement Co. on the mainland; the former company is planning an output of 30,000 tons per annum, and the latter is expecting to produce in July next.

Lessons in Economic Independence.—The manufacture of calcium carbide was developed in Tasmania during the war, and was safeguarded owing to shipping difficulties. It was just beginning to become well established when the shipping situation improved, and the old importers began to attempt to recover their market by offering carbide at a "cut" price. In consequence, the Federal Government prohibited the importation of carbide, except under licence, for a period of twelve months, by which time it is anticipated that the new tariff law will be in operation.

A different story is that of imported petrol, which is not produced in the country. The importers of this commodity (the price of which is fixed by law) applied to the Court for permission to increase the price, and when they were asked by the President of the Court what would happen if their request were refused, they replied that the importation would cease. The application was granted.

JAPAN.

The Camphor Industry.—The efforts made by the Japanese Camphor Monopoly to increase production resulted in 1919 in a yield of nearly 6·7 million lb., of which 5·7 million lb. came from Formosa. Although this was nearly double the 1918 output, it was approximately 20 per cent. less than that for 1916, a year of record production. On account of the rapid growth of the Japanese celluloid industry, the exportable surplus is becoming smaller, and in 1919 the United States received only 1·42 million lb., compared with 2·5 million lb. before the war.—(*Chem. Ind., Mar.* 14, 1921.)

FRANCE.

Industrial Notes.—*Coal.*—One immediate effect of the coal strike in Great Britain was to stimulate the French coal trade. The fear of a short supply of coal has been strongest in the south-west and south, where British coal is mainly consumed. It is estimated that the increase in orders arising from this cause is about 350,000 tons.

According to the report of the Central Committee of the French Coalfields, the production of coal in France rose from 22,341,864 metric tons in 1919 to 25,274,294 t. in 1920. Importations in 1920 were 24,056,262 t. of coal, 3,985,213 t. of coke, and 2,070,893 t. of briquettes, compared with 22,005,000 t., 1,723,619 t., and 1,180,139 t. respectively in 1919. British exports to France in 1920 amounted to 11,432,000 t. of coal, 667,000 t. of coke, and 887,000 t. of briquettes, and showed a great reduction over the figures for 1919; this was due to increased supplies from Germany and the Saar basin, and to importations from the United States. The total supplies in the past year were thus 48,359,000 t. of coal, 4,767,000 t. of coke, and 4,129,000 t. of briquettes, or 4 million tons of coal and 2¼ million tons of coke in excess of the supplies in 1919; but the ratio of production to consumption, 50 per cent., compares unfavourably with that for the last pre-war year, viz., 65 per cent. The production of the Saar and Lorraine coalfields—about 7 million tons—is about 4 million tons less than the consumption in the recovered provinces. There is, moreover, little prospect of increased output in view of the 8-hour day and the diminished efficiency of the individual miner.

Metallurgy.—The greatly increased production of cast iron and steel resulting from the return of Alsace-Lorraine has emphasised the importance of finding outlets abroad, and this question is being considered by the Ministries of Commerce, Public Works, and Industrial Reconstruction in conjunction with representatives of the industry. As a result of combination between important metallurgical firms, production costs have been reduced and the general commercial organisation improved and strengthened so as to obtain a firmer hold on foreign markets. The Comptoir Sidérurgique has lately added to its list of members the iron and steel firms of the Saar basin, but as these refuse to enter the export trade, the Comptoir is at present dealing solely with the home trade, although its chief function should be to promote exportation.

Chemical Industry.—Soap can now be exported freely, and it is to be hoped that complete freedom will soon be forthcoming, as this would be followed by a material reduction in prices. The slump on the chemical market still continues, and were it not for exportation the situation would be critical. Abroad there is acute competition from England, Germany, and the United States, and the last-named country is daily gaining a firmer hold on the South American market, formerly supplied by Germany.

The projected publication of all chemical abstracts in *Chimie et Industrie* and *Le Bulletin de*

la Société chimique de France (*cf.* J., 1921, 127 R) is generally welcomed by chemists, if only on account of the time that will be saved in searching in one or two journals for matter which may now be dispersed in many.

UNITED STATES.

Recent Research in Applied Chemistry.—*Carbon Black.*—A new process for producing carbon black is being rapidly perfected. It consists in forcing natural gas, consisting of nearly pure methane, through molten metal and collecting the resulting carbon black by the Cottrell process, hydrogen being liberated as a by-product.

Syrup from Sweet Potatoes.—The Bureau of Chemistry has devised a process of manufacturing a table syrup from sweet potatoes, of which large quantities do not now reach the market. The syrup is rich in sugar, has a good brown colour, is palatable, and suitable for baking, for making sweets, and for table purposes. It is considered by many to be equal to a high-grade, cane-sugar table syrup.

Tarnishing of Metal Surfaces.—A research laboratory which is investigating problems relating to the protection of metal surfaces has found that tarnish on highly-polished machine parts is often due to sunlight. This result is brought about by very slow breaking down of some of the hydrocarbons in the lubricating oil, carbon being deposited and hydrogen set free. The brown stain produced is indelible, but harmless.

Testing the Fastness to Light of Dyes.—A series of tests to ascertain the best means of determining the fastness to light of dyes has been completed, and the decision reached that the violet carbon arc gives results which agree best with the effect of sunlight. The white-flame carbon arc gave rather better results, but was only half as rapid. These carbon arcs were found to be superior in constancy to the mercury arc.

Chlorination of Natural Gas.—The chlorination of natural gas in localities where other economical use is excluded seems a certainty for the near future. Investigations conducted by the Bureau of Mines have shown the possibility of producing the four chloromethanes, etc., with a 90 per cent. or better yield, and the only remaining problem is that of heat control.

Applications of Carbonyl Chloride.—Phosgene is known to be very reactive at or above 450° C., and Dr. Charles Baskerville has utilised it to convert the oxides of aluminium and cerium, insoluble in acids, and the oxides of zirconium and thorium, which are soluble only in boiling concentrated sulphuric acid, directly into water-soluble chlorides or oxychlorides. Bauxite and carborundum gave ferric and aluminium chlorides, and zircon yielded zirconium chloride, the ferric chloride from the contaminating iron being distilled off owing to its greater volatility. The method consists in simply heating the pulverised material in a quartz tube in a current of the gas.

Wood-alcohol Poisoning.—Many deaths have occurred in the United States as the result of drinking wood alcohol, and various preventive measures have been discussed. It was pointed out by Mr. A. E. Outerbridge that the addition of a small amount of fluorescein to denatured alcohol, although invisible in the concentrated solution, would give on dilution a yellowish-green fluorescence that would immediately be noticeable and would therefore serve as a deterrent. Accordingly a sample of denatured alcohol containing 7 mg. of fluorescein per 100 c.c. was submitted to the Prohibition Commissioner, who gave the opinion, in a letter to *Chemical and Metallurgical Engineering* of March 2, that it was inexpedient to use fluorescein for this purpose, as the colour that becomes apparent on dilution might prove objectionable in some manufacturing processes; the voluntary addition of fluorescein to a factory stock of completely or specially denatured alcohol, however, was highly desirable.

Potash Discovery in Texas.—A large deposit of alunite has been discovered near Floresville, Texas. Three outcrops of the mineral occur, separated from one another by six to twelve miles, and the outcrop of highest grade mineral covers about 20 acres. The commercial value of the alunite is said to be about $250 per ton, and should it be possible to exploit the deposits commercially, an important source of potash will be made available.—(*Oil, Paint and Drug Rep., Mar.* 14, 1921.)

The American Oil Chemists' Society.—For many years the leading chemists in the cottonseed oil industry have been associated in the Society of Cotton Products Analysts, an organisation which was devoted primarily to perfecting methods of analysis used in the cottonseed industry. Certain specific qualifications for membership limited this society in numbers to those highly specialised but ensured a large amount of important investigation work. During the war the United States was drawn into a large international trade in several of the vegetable oils which became keen competitors of cotton oil, and this caused a commensurate widening of the society's interests with the result that at its annual meeting in May, 1920, it was re-organised under the name of the American Oil Chemists' Society. All persons engaged in chemical work relating to fats, oils, waxes, and allied substances are eligible for active membership in the new society, provided they have had at least five years' chemical training. Meetings are held once a year, usually in May, and in conjunction with the Inter-State Cotton Crushers' Association. The Society publishes regularly its transactions and maintains the Chemists Section of the Cotton Oil Press, a journal devoted exclusively to the interests of the edible vegetable-oil industry. Membership, however, is not limited to chemists and technologists engaged exclusively in the edible oil trade, but includes also those concerned with its industrial or technical aspects. Anyone interested in the activities of this new organisation may obtain further information from the secretary and treasurer, Mr. T. B. Caldwell, Wilmington, N.C.

BRITISH INDIA.

Chemical and Allied Industries in Madras.—The Acting Director of Industries, Madras, in a summary of industrial intelligence appearing in the first number of the *Journal of Indian Industries and Labour*, points out that the high price and scarcity of fuel is one of the main difficulties which hinder the development of industries in Southern India. Numerous discoveries of coal have been made in the Presidency from time to time, the most promising being those made in the Godaveri and Kistna Districts. Endeavours to interest firms and syndicates in the exploitation of the fields have in so far been successful that a leading Madras firm has been granted a prospecting licence over a total area of 173 sq. miles in the Kistna district and over 80 sq. miles in the Godaveri district.

The question of a possible cement industry at Bezwada has been investigated for the past three years, and it now seems probable that it will soon be established, as the Government has recently approved of the grant to a syndicate of rights in certain districts for mining and quarrying the limestone and shale required in the manufacture. One of the conditions governing the grant of the concession is that within four years an output of at least 30,000 tons of cement per annum must have been attained.

A collection of samples of aromatic gums and oleo-resins, available in commercial quantities in Madras forests, was made for a large London firm of manufacturing chemists, which was also supplied with full information about the sources of supply and quantities available. The firm is considering the establishment in Southern India of a factory for the manufacture of drugs and essential oils. Another London firm of manufacturing chemists is contemplating the erection at Vizagapatam of a factory for producing crude alkaloids, principally strychnine, from nux vomica. The firm has already acquired the necessary land, and a factory will be erected at an early date.

The exploitation and development of the deposits of phosphatic nodules in the Trichinopoly District, with a view to supplying this fertiliser at cheap rates to the ryots of the delta districts, has been under consideration for some time past. It is proposed to establish an experimental works for the production of finely-ground phosphate and for the exploitation of the gypsum and red ochre associated with the nodules.

The industrial chemist attached to the Department of Industries is investigating at the Indian Institute of Science, Bangalore, the fermentation vat for indigo dyeing, and the fermentation of prickly pear. The production of power alcohol and the suitability of South Indian woods for the manufacture of paper and pulp are also being considered.

The manufacture of inks and vinegar is being carried out at the Government Industrial Laboratory, Coonoor. Experiments in progress at the laboratory include the manufacture of casein glue, lacquer for tins, sealing wax, and an investigation into the available sources of pectin.

As a result of the experiments in the manufacture of glue which were undertaken by the Department, agreements have been made for the establishment of a small experimental factory in Madras. Other schemes being considered by private firms, with the assistance of the Department, are the manufacture of finished rubber goods, extraction of oil from groundnut and gingelly seeds, manufacture of pottery and porcelain ware, and a factory for the production of cane sugar.

Second Forecast of Winter Oilseeds.—The total area under rape and mustard, so far reported, amounts to 2,793,000 acres, or 22 per cent. below the revised figure at the corresponding date of last year. The total area under linseed is reported to be 1,784,000 acres, which is 23 per cent. below last year's second forecast. In both cases these figures exclude the "mixed" crop of the United Provinces. The condition of the crops is reported to be generally fair. —(*Ind. Tr. J., Mar.* 18, 1921.)

SOUTH AFRICA.

Mining in the Protectorate of South-West Africa.—Since the country was opened for prospecting on March 1, 1920, there has been considerable mining activity; copper ore has been found in the Kaokoveld, galena and silver in the Kalkfontein district, discoveries of tin and iron are reported from the Usakos district, and oil-shales have been discovered in the Gibeon district. Copper ore traffic, which recommenced in August, 1919, has been steadily maintained, and an average of about 3000 t. per month has been dispatched during the last few months. The tin mines have been more active, and although they are not able to record a large production, owing to lack of machinery, the output has increased considerably. About 50 tons of scheelite was produced at the Natas mine in 1919, the output of marble has notably increased, and 948 tons of salt was dispatched by rail during the year. The value of the diamond output for 1919 was £1,500,000, the production (426,180 carats) showing a large increase over the previous year.

A writer in the *Star* (Johannesburg) states that the tinfields situated in the Karibib and Omaru districts extend over several hundreds of square miles and that their production will expand considerably. One of the properties has recently been acquired by a leading Rand mining house, and another has been taken up by an East London company. Mining methods have hitherto been very primitive, but modest profits have been won. The obstacles to development are lack of water and transport.—(*S. Afr. J. Ind., Feb.*, 1921.)

GENERAL.

Finsbury Technical College.—When the projected closing of the City and Guilds Technical College, Finsbury, was announced last July, students past and present, and many friends who appreciated the educational facilities offered at this College during nearly forty years, endeavoured to avert the disaster. A Defence Committee was formed which was composed largely of former students, and urgent protests were evoked almost spontaneously from the great professional institutions. As a result, two petitions were sent to the City and Guilds of London Institute, one signed by the presidents of many of the professional institutions, and the other signed by a large number of former students of the College and friends interested in its continuance. In reply the petitioners were informed that there was every hope that the College would be continued, with the help of the Board of Education and the London County Council, for a period of five years. The success of these negotiations has now been announced, and it is hoped that the future of the College is now assured. The members of the Defence Committee are very grateful for the help given by many friends of the College during the critical period which has now passed.

The Imperial Mineral Resources Bureau.—The second annual report, covering the year 1920, shows that excellent progress has been made in the organisation and work of the Bureau. Good headway has been made in the collection of information, both from the appointed corresponding members and from unofficial sources, and in its co-ordination and tabulation. The information so obtained is made available to all Government Departments both at home and overseas, as well as to co-operating technical institutions and societies; individuals and companies may also avail themselves of the service of the Bureau, but these are charged a nominal fee if information is asked for which involves special work by the staff. Important work is being done with a view to introducing a unified system of mining and metallurgical statistics, including the standardisation of weights and measures, and at the suggestion of the Bureau a resolution was passed at the Imperial Statistical Conference to the effect that when the projected Central Bureau of Statistics for the Empire comes into being, it shall work hand-in-hand with the Imperial Mineral Resources Bureau. It has also been arranged that the Bureau shall have charge of the mineral exhibit at the British Empire Exhibition to be held in 1923. The Technical Advisory Committees constitute an important feature of the organisation; they are fifteen in number and comprise 148 of the leading authorities on the respective minerals and the industries associated therewith. Sir Herbert Jackson is chairman of the Committee for Chemical Industries.

The work of indexing technical literature of the Empire and of foreign countries is being actively prosecuted, and during the year ten pamphlets, each relating to one metal or mineral, were published; twelve more were nearly ready for press

at the end of the year, and another eight were in course of preparation. Future publications of this type will include statistics relating to labour, health, and accidents. A special and comprehensive work on the "Iron Ore Resources of the World" is also being prepared. The Legal Section of the Bureau has completed two volumes dealing with Mining Law in Nigeria and West Africa, respectively, and a third on South Africa, with special reference to the Transvaal, is nearing completion. The Bureau was supported financially by grants which amounted to £20,452, of which £10,000 was from the Imperial Government, and the rest from the Overseas Dominions and the National Federation of Iron and Steel Manufacturers. The paid staff numbers 45 persons, exclusive of the chairman, Sir Richard Redmayne, and the vice-chairman.

"Cobalt (1913—1919)" (Imperial Mineral Resources Bureau pamphlet, 22 pp., price 9d.).—Although the results of research indicate the possible value of cobalt metal as a constituent of alloys and in electro-plating, commercial interest lies chiefly in the use of its salts in the pottery and enamelling trades. The oxide has largely superseded smalt (silicate) as a colouring agent owing to its greater purity, uniformity, and lower cost. For special purposes the carbonate, chloride, sulphate, and, less commonly, aluminate, phosphate, arsenate, and nitrate are also employed. As driers in the paint and varnish trade the acetate, resinate, and oleate of cobalt are used. During the war a cobalt-chromium alloy ("Stellite") found some application in the manufacture of cutting and milling tools.

The world's annual production of cobalt oxide up to 1913 amounted approximately to 250 tons. Before the discovery of cobalt ore in Ontario, New Caledonia produced over 80 per cent. of the world's supply. In recent years Canada has been the chief producing country, the actual figures for 1918, quoted from the Report of the Canadian Mines Department, being metallic cobalt 196 tons, cobalt oxide 512 tons, and other compounds 83 tons. The production of Katanga, in the Belgian Congo, promises to be of some importance, and considerable interest has lately been shown in a new deposit which is being actively exploited in the Cloncurry district of Queensland (*cf.* J., 1920, 378 R, and this issue, p. 148 R).

The price of cobalt oxide in July, 1919, was quoted in London at 7s. 8d. per lb. For some unexplained reason it rose during 1920 to 20s. per lb., but has since fallen to 16s. per lb. nominal.

British Yeast.—The "Report on Yeast" by the sub-committee of the Standing Committee on Trusts (Cmd. 1216. 2d.) states that compressed distillers' yeast has almost entirely superseded brewers' yeast for use in bread-making, and that nearly the whole home-supply is produced by three firms, two of which are located in Edinburgh and one in Belfast. The pre-war selling price, inclusive of delivery, was about 19s. per 56-lb. basket, and the present price of about 39s. represents an increase in the cost of bread of less than 0·1d. per loaf. No information concerning production costs was forthcoming. From the time it leaves the distillery until it reaches the consumer, the yeast is controlled by the Wholesale Yeast Merchants' Association, together with its subsidiary yeast dealers' associations, and these in turn are controlled or influenced by the representatives or agents of the distillers; no person outside these associations could obtain supplies of British yeast.

Before the manufacture of compressed distillers' yeast was started in this country in 1886, foreign yeast was imported at the rate of about 282 tons per week, but owing to the competition of the home-produced material the imports had declined to about 200 t. per week immediately before the war. From 1915 to 1917 imports were gradually restricted, and from April, 1917, to April, 1919, were prohibited. Importation was resumed in 1919, and now about 70 tons is being imported weekly. During the period of prohibition the output of British distilleries rose from about 400 t. to 650—700 t. a week, and at the present time the home consumption is estimated at about 635 t. a week. When, during the war, the distillers were invited by the Ministry of Munitions to enlarge their plants in order to meet the entire home demand, the Ministry is said to have given them some sort of assurance that importation would be restricted after the war; but this has been denied. The conclusion arrived at by the sub-committee is that unrestricted imports form the only safeguard against a combination of distillers arbitrarily fixing the price to the consumer, and should it be found necessary to protect the British distillers against imported yeast, such action should be preceded by legislation to protect the consumer by providing for the surveillance of trusts and monopolies.

Use of Peat Fuel on Swedish Railways.—Extensive trials have shown that peat, reduced to powder or briquetted, makes an excellent substitute for coal as fuel for locomotives (*cf.* J., 1919, 145 R), and the Swedish Railway Board has taken over the plant at Hästhagen bog, near Vislanda, which cost 975,000 kronor (krona=1s. 1½d. at par) and has a capacity of 30,000 tons per annum. The power required by the plant is small, and the peat is air-dried as far as possible, the hardest and driest lumps being used as ordinary fuel and the remainder pulverised or briquetted. Various new machines and devices for digging, transporting and drying peat have been devised by Engineer Eklund, and it is proposed to manufacture them in a new factory.—(*U.S. Com. Rep., Feb.* 25, 1921.)

The Norwegian Paper Industry.—In this industry there are 26 cellulose mills, 63 wood-pulp grinding mills, 48 paper and cardboard factories, and about 15,000 workers. The production in 1918 was 438,438 tons of cellulose and wood pulp, and 116,889 t. of paper and cardboard. At present there is little demand for paper, stocks are accumulating, and the situation is not bright. Many mills have had to reduce their output, some have been closed, and about one-half of the 80 paper machines is lying idle. The production of wood pulp has as yet only been reduced where it is required for paper-making; stocks of cellulose and wood pulp are not so large as those of paper.—(*U.S. Com. Rep., Feb.* 6, 1921.)

Projected Salt and Magnesium Industries in Norway.—The A.-S. Norske Saltverker is erecting a factory for the extraction of salt from sea water in Fjotlandsvaag. The factory will have a capacity of 5000 t. per annum, and will probably be finished in the summer. It is intended to utilise the magnesium salts for the production of about 100 tons of magnesium yearly, *i.e.*, about one-quarter of the world's present production. The magnesium will in part be made into alloys for constructing motors, aircraft, balances, conductivity wiring, etc. For such purposes the alloy or metal will be covered with a protective film of oxide by a process, discovered by the engineer Backer, which consists in boiling in water under high pressure for about 15 minutes; the resulting coating is said to be firmly adherent even when hammered, and to act as an electrical insulator.—(*Chem. Ind., Mar.* 28, 1921.)

Belgian Coal Output in 1920.—The Belgian output of coal in 1920 was 22,414,000 metric tons, which compares with 18,483,000 t. in 1919 and 22,842,000 t. in 1913. The average output per shift per face worker was 2802 to 3696 t. Coke production has now attained 1,800,000 t., as against 757,000 t. in 1919 and 3,523,000 t. in 1913, and the coke-ovens

consumed 2,343,000 t. of coal, of which 379,000 t. was imported. Owing to increased use on the Belgian railways, the output of briquettes rose from 2,458,000 t. in 1919 to 2,922,000 t. in 1920. Exports, largely to France, amounted to 1,638,000 t. of coal, 219,000 t. of coke, and 215,000 t. of briquettes; imports were 1,541,000 t. of coal, 124,000 t. of coke, and 152,000 t. of briquettes, Germany, Great Britain, and the United States supplying 1,211,000 t., 301,000 t., and 28,000 t., respectively. The total consumption of fuel amounted to 22,449,000 t., or 86 per cent. of the consumption in 1913.—(*Iron and Coal Tr. Rev., Mar.* 25, 1921.)

Position of the German Potash Industry.—In reply to an inquiry made by the French delegates at the Brussels Conference, the German delegates stated that the German potash industry was now operating 201 shafts, 74 factories which produce chloride and sulphate of potassium, 8 special factories where salts from other works are treated, and also factories that work up by-products, such as bromine and magnesium chloride. Owing to the small demand and lack of coal, production was being still further reduced, especially in Hannover. The present production, however, could be more than doubled without sinking new shafts or erecting new plant, etc., and it could be increased many times were transport and labour conditions slightly better. Handling facilities were good, the works were all interconnected by rail, and adequate means were available for conveyance by water to the seaports.—(*Z. angew. Chem., Feb.* 11, 1921.)

The German Leather Industry in 1920.—On the whole, 1920 was a good year for German leather manufacturers, but fine leather-ware was in little demand. When the industry was freed from Government restrictions in August, 1919, the importation of raw materials again became possible, and such war-time substitutes as wooden soles, paper fabric, etc., disappeared completely, although wooden heels are still made. As the export duty on leather products restricted the proper development of the export trade, the Government removed the duty so far as it affected the finer grades of leather and leather goods. The export trade fluctuated during the year and is still unsatisfactory, as the former German markets are well stocked and are making strenuous efforts to ward off German competition. The German leather factories use mainly lignite as fuel; they have suffered from frequent interruptions in the supply of electric light and power, and the increased railway rates, which became effective on December 1 last, will be acutely felt by the industry.—(*U.S. Com. Rep., Mar.* 3, 1921.)

Sugar Production in Europe.—During the last six years the production of sugar in Europe has fallen by about 66 per cent., and Germany, formerly the largest exporter, cannot now supply her own needs. The European sugar production for the years 1913–14 and 1919–20 is given below:—

	1913-14.	1919-20.
	Million metric tons.	
Germany	2·738	0·750
Austria-Hungary (former)	1·688	0·585
Holland	0·231	0·238
Sweden	0·137	0·145
Denmark	0·146	0·160
Belgium	0·229	0·127
France	0·781	0·175
Russian Empire (former)	1·688	0·350
Other countries	0·543	0·300
Totals	8·181	2·830

Apart from political considerations, the large decrease in Germany is ascribed mainly to the high price of fertilisers, particularly nitrogenous fertilisers, which are chiefly used in great quantities for sugar-beet. Germany has lost important producing areas, but certain sugar factories in South Germany have formed an "Interessengemeinschaft" to further the development of the industry.—(*Schweiz. Chem.-Z., Mar.* 1, 1921.)

Indigo in Java.—Indigo is grown on about 40 estates in Java as well as by the natives. The estate indigo contains from 60 to 80 per cent. of indigotin, but the native product, which is used locally, contains only 0·75 to 1 per cent. Before the war Holland took most of the powder and Singapore the paste, but since 1917 Japan has purchased the bulk of the powder. Singapore became an important market for the product during 1920.—(*U.S. Com. Rep., Feb.* 19, 1921.)

Drug Manufacture in Petrograd.—During the period July—September, 1920, four State drug factories and four private factories were in operation. Two of the State factories produced:—Liquid medicines, 14,924 kg., powders, 7509 kg., ointment, 2444 kg., plasters, 65 kg., chemical and mineral preparations, 789 kg., chemical dressings, 1,500,000 kg., and iodine, 150 kg. The other two factories and the private laboratories manufactured sweetening material solely, the production in the above-mentioned period amounting to 196 kg. There was a general shortage of all raw materials, particularly fats.—(*Chem. Ind., Mar.* 28, 1921.)

PERSONALIA.

Dr. Morris W. Travers has been elected president of the Society of Glass Technology for the ensuing year.

The new chair of biochemistry at Cambridge University, to be known as the Sir William Dunn chair, has been offered to and accepted by Prof. F. Gowland Hopkins, fellow and prelector in biochemistry at Trinity College.

Mr. F. W. Harbord has been elected president of the Institution of Mining and Metallurgy in succession to Mr. Frank Merricks. Mr. Benedict Kitto, and Prof. R. Peele, of Columbia University, New York, have been elected honorary members.

Prof. E. Lagueur has been appointed professor of pharmacology and director of the Pharmacological Institute in the University of Amsterdam.

The eightieth birthday of Prof. K. Graebe, the discoverer of synthetic alizarin, was celebrated recently in his native town, Frankfurt-on-the-Main. Prof. Graebe occupied the chair of chemistry at Geneva University from 1878 to 1906, and last year he published a history of organic chemistry.

Prof. R. Scholl, of Dresden, has been appointed to the chair of chemistry at Vienna, in succession to Prof. Schlenk, who is to succeed Emil Fischer in the University of Berlin.

The following appointments, etc., at German Technical "Hochschulen" have been notified:—Prof. Schuberg to be head of the chemical department at Charlottenburg, in succession to Prof. Dolezalek; Dr. L. Moser to the chair of analytical chemistry at Vienna; Dr. Alex. Classen is retiring from the chair of inorganic chemistry and electrochemistry at Aachen.
